If you just want to hide the window, you can press Shift while clicking the close button. This skips the dialog and just hide the window.

Killing a procedure window closes the window and removes it from the current experiment but does not delete or otherwise affect the procedure file with which the window was associated. If you have made changes or the procedure was not previously saved, you will be presented with the choice of saving the file before killing the procedure.

The Close item of the Windows menu and the equivalent, Command-W (*Macintosh*) or Ctrl+W (*Windows*), behave the same as the close button, as indicated in these tables.

Macintosh:

Actions	Modifier Key	Result
Click close button, choose Close, press Command-W		Displays dialog
Click close button, choose Close, press Command-W	Shift	Hides window
Click close button, choose Close, press Command-W	Option	Displays dialog

Windows:

Actions	Modifier Key	Result
Click close button, choose Close, press Ctrl+W		Displays dialog
Click close button, choose Close, press Ctrl+W	Shift	Hides window
Click close button, choose Close, press Ctrl+W	Alt	Displays dialog

Macintosh: When the Close Procedure Window dialog is showing, you can press Option to make the Kill button the default. The Kill button will become bold while the "Save and then kill" button will become normal. You can then press Return or Enter to kill the window. Similarly, press Shift to make the Hide button the default button.

Shared Procedure Files

You may develop procedures that you want to use in several but not all of your experiments. You can facilitate this by creating a shared procedure file. This is a procedure file that you save in its own file, separate from any experiment. Such a file can be opened from any experiment.

There are two ways to open a shared procedure file from an experiment: by explicitly opening it, using the File→Open File submenu or by adding an include statement to your experiment procedure window. The include method is preferred and is described in detail under **Including a Procedure File** on page III-346.

When Igor encounters an include statement, it searches for the included file in "Igor Pro Folder/User Procedures" and in "Igor Pro User Files/User Procedures" (see **Igor Pro User Files** on page II-46 for details). The Igor Pro User Files folder is the recommended place for storing user files. You can locate it by choosing Help→Show Igor Pro User Files.

You can store your shared procedure procedure file directly in "Igor Pro User Files/User Procedures" or you can store it elsewhere and put an alias (*Macintosh*) or shortcut (*Windows*) for it in "Igor Pro User Files/User Procedures". If you have many shared procedure files you can put them all in your own folder and put an alias/shortcut for the folder in "Igor Pro User Files/User Procedures".

When you explicitly open a procedure file using the Open File submenu, you are adding it to the current experiment. When you save the experiment, Igor saves a *reference* to the procedure file in the experiment file. When you close the experiment, Igor closes the procedure file. When you later reopen the experiment, Igor reopens the procedure file.

When you use an include statement, the included file is not considered part of the experiment but is still referenced by the experiment. Igor automatically opens the included file when it hits the include statement during procedure compilation.

Note: There is a risk in sharing procedure files among experiments. If you copy the experiment to another computer and forget to also copy the shared files, the experiment will not work on the other computer. See **References to Files and Folders** on page II-37 for more explanation.

Saving Shared Procedure Files

If you modify a shared procedure file, Igor saves it when you save the experiment that is sharing it. However, you might want to save the procedure file without saving the experiment. For this, choose File→Save Procedure.

Global Procedure Files

Global procedure files contain procedures that you want to be available in *all* experiments. They differ from other procedure files in that Igor opens them automatically and never closes them.

When Igor starts running, it searches "Igor Pro Folder/Igor Procedures" and "Igor Pro User Files/Igor Procedures" (see**Igor Pro User Files** on page II-46 for details), as well as files and folders referenced by aliases or shortcuts. Igor opens any procedure file that it finds during this search as a global procedure file.

You should save your global procedure files in "Igor Pro User Files/Igor Procedures". You can locate this folder by choosing Help→Show Igor Pro User Files.

Igor opens global procedure files with write-protection on since they presumably contain procedures that you have already debugged and which you don't want to inadvertently modify. If you *do* want to modify a global procedure file, click the write-protect icon (pencil in lower-left corner of the window).

When you create a new experiment or open an existing one, Igor normally closes any open procedure files, but it leaves global procedure files open. You can explicitly close a global procedure window at any time and then you can manually reopen it. Igor will not automatically reopen it until the next time Igor is launched.

Although its procedures can be used by the current experiment, a global procedure file is not part of the current experiment. Therefore, Igor does not save a global procedure file or a reference to a global procedure file inside an experiment file.

Note: There is a risk in using global procedure files. If you copy an experiment that relies on a global procedure file to another computer and forget to also copy the global procedure file, the experiment will not work on the other computer.

Saving Global Procedure Files

If you modify a global procedure file, Igor will save it when you save the current experiment even though the global procedure file is not part of the current experiment. However, you might want to save the procedure file without saving the experiment. For this, use the File→Save Procedure menu item.

Including a Procedure File

You can put an include statement in any procedure file. An include statement automatically opens another procedure file. This is the recommended way of accessing files that contain utility routines which you may want to use in several experiments. Using an include statement is preferable to opening a procedure file explicitly because it doesn't rely on the exact location of the file in the file system hierarchy.

Here is a typical include statement:

```
#include <MatrixToXYZ>
```

This automatically opens the MatrixToXYZ.ipf file supplied by WaveMetrics in "Igor Pro Folder/WaveMetrics Procedures/Data Manipulation". The angle brackets tell Igor to search the "Igor Pro Folder/WaveMetrics Procedures" hierarchy.

To see what WaveMetrics procedure files are available, choose Help→Help Windows→WM Procedures Index.

You can include your own utility procedure files by using double-quotes instead of the angle-brackets shown above:

```
#include "Your Procedure File"
```

The double-quotes tell Igor to search the "Igor Pro Folder/User Procedures" and "Igor Pro User Files/User Procedures" hierarchies (see **Igor Pro User Files** on page II-46 for details) for the named file. Igor searches those folders and subfolders and files or folders referenced by aliases/shortcuts in those folders.

These are the two main variations on the include statement. For details on less frequently used variations, see **The Include Statement** on page IV-145.

Included procedure files are not considered part of the experiment but are automatically opened by Igor when it compiles the experiment's procedures.

To prevent accidental alteration of an included procedure file, Igor opens it either write-protected (User Procedures) or read-only (WaveMetrics Procedures). See **Write-Protect Icon** on page III-342.

A #include statement must omit the file's ".ipf" extension, if it has one:

```
#include <Strings as Lists>      // RIGHT

#include <Strings as Lists.ipf>  // WRONG
```

See **Cross-Platform Procedure Compatibility** on page III-404 for details.

Creating Packages

A package is a set of procedure files, help files and other support files that add significant functionality to Igor.

Igor comes pre-configured with numerous WaveMetrics packages accessed through the Data→Packages, Analysis→Packages, Misc→Packages, Windows→New→Packages and Graph→Packages submenus as well as others.

Intermediate to advanced programmers can create their own packages. See **Packages** on page IV-222 for details.

Invisible Procedure Files

If you create a package of Igor procedures to be used by regular Igor users (as opposed to programmers), you may want to hide the procedures to reduce clutter or to eliminate the possibility that they might inadvertently change them. You can do this by making the procedure files invisible.

Invisible procedure files are omitted from Igor's Procedure Windows submenu which appears in the Windows menu. This keeps them out of the way of regular users.

There are three ways to make a procedure file invisible. In order of difficulty they are:

- Using the "#pragma hide" compiler directive
- Using an independent module
- Using the operating-system-supplied file visibility property

Invisible Procedure Windows Using #pragma hide

In Igor Pro 6.1 or later, you can make a procedure file invisible by inserting this compiler directive in the file:

#pragma hide=1

This prevents the procedure window from being listed in the Windows→Procedures submenu but only if the window is opened for read-only or is write-protected using Igor's write-protect icon (see **Write-Protect Icon** on page III-342). Since Igor automatically turns write-protect on for #included files, this method is easy to use with them.

Procedures windows that include this compiler directive and which are read-only or write-protected become invisible on the next compile.

You can make these windows visible during development by executing:

```
SetIgorOption IndependentModuleDev=1
```

and return them to invisible by executing:

```
SetIgorOption IndependentModuleDev=0
```

You must force a compile for this to take effect.

Invisible Procedure Windows Using Independent Modules

You can also make a set of procedure files invisible by making them an independent module. The independent module technique is more difficult to implement but has additional advantages. For details, see **The IndependentModule Pragma** on page IV-43.

Invisible Procedure Files Using The Files Visibility Property

This section discusses making procedure files invisible by setting the operating-system-supplied file "visible" property.

Note: This is an old technique that is no longer recommended. It may not be supported in future versions of Igor.

When Igor opens a procedure file, it asks the operating system if the file is invisible (*Macintosh*) or hidden (*Windows*). We will use the term "invisible" to mean invisible on Macintosh and hidden on Windows.

If the file is invisible, Igor makes the file inaccessible to the user. Igor checks the invisible property only when it opens the file. It does not pay attention to whether the property is changed while the file is open.

You create Igor procedures using normal visible procedure files, typically all in a folder or hierarchy of folders. When it comes time to ship to the end user, you set the files to be invisible. If you set a file to be invisible, you should also make it read-only.

You can use the **SetFileFolderInfo** operation (see page V-557) to set the visibility and read-only properties of a file:

```
SetFileFolderInfo /INV=1 /RO=1 "<path to file>"
```

The file will be invisible in Igor the next time you open it, typically by opening an experiment or using a #include statement.

The file will still be visible in the Macintosh Finder until you restart the Finder.

On Windows, merely setting the hidden property is not sufficient to actually hide the file. It is actually hidden only if the Hide Files of These Types radio button in the View Options dialog is turned on. You can access this dialog by opening a folder in the Windows desktop and choosing View→Options from the folder's menu bar. Although the hidden property in Windows does not guarantee that the file will be hidden in the Windows desktop, it does guarantee that it will be hidden from within Igor.

After the files are set to be invisible and read-only, if you want to edit them in Igor, you must close them (typically by closing the open experiment), set the files to be visible and read/write again, and then open them again.

Igor's behavior is changed in the following ways for a procedure file set to invisible:

1. The window will not appear in the Windows→Procedure Windows menu.
2. Procedures in the window will not appear in the Procedure pop-up menu at the bottom of all procedure windows.
3. Procedures in the window will not appear in the contextual pop-up menu in other procedure windows (Control-click on *Macintosh*, right-click on *Windows*).
4. If the user presses Option (*Macintosh*) or Alt (*Windows*) while choosing the name of a procedure from a menu, Igor will do nothing rather than its normal behavior of displaying the procedure window.
5. When cycling through procedure windows using Command-Shift-Option-M (*Macintosh*) or Ctrl+Shift+Alt+M (*Windows*), Igor will omit the procedure window.
6. The Button Control dialog, Pop-Up Menu Control dialog, and other control dialogs will not allow you to edit procedures in the invisible file.
7. The Edit Procedure and Debug buttons will not appear in the Macro Execute Error dialog.
8. If an error occurs in a function in the invisible file and the Debug On Error flag (Procedure menu) is on, the debugger will act as if Debug On Error were off.
9. The debugger won't allow you to step into procedures in the invisible file.
10. The **ProcedureText** function (see page V-506) and **DisplayProcedure** operation (see page V-118) will act as if procedures in the invisible file don't exist. (The **MacroList** and **FunctionList** functions will, however work as usual.)
11. The GetIgorProcedure and SetIgorProcedure XOPSupport routines in the XOP Toolkit will act as if procedures in the invisible file don't exist. (The GetIgorProcedureList function will, however work as usual.)

Inserting Text

On occasion, you may want to copy text from one procedure file to another. The Insert File item in the Edit menu makes this easy. With the procedure window active, choose Insert File. This will display a dialog in which you can find the file and will then insert its contents into the procedure window.

Adopting a Procedure File

Adoption is a way for you to copy a procedure file into the current experiment and break the connection to its original file. The reason for doing this is to make the experiment self-contained so that, if you transfer it to another computer or send it to a colleague, all of the files needed to recreate the experiment will be stored in the experiment itself.

To adopt a file, choose Adopt Window from the File menu. This item will be available only if the active window is a notebook or procedure file that is stored separate from the current experiment and the current experiment has been saved to disk.

If the current experiment is stored in packed form then, when you adopt a file, Igor does a save-as to a temporary file. When you subsequently save the experiment, the contents of the temporary file are stored in the packed experiment file.

If the current experiment is stored in unpacked form then, when you adopt a file, Igor does a save-as to the experiment's home folder. When you subsequently save the experiment, Igor updates the experiment's recreation procedures to open the new file in the home folder instead of the original file. If you adopt a file in an unpacked experiment and then you do not save the experiment, the new file will still exist in the home folder but the experiment's recreation procedures will still refer to the original file. Thus, you should normally save the experiment soon after adopting a file.

Adoption does not cause the original file to be deleted. You can delete it from the desktop if you want.

To "unadopt" a procedure file, choose Save Procedure File As from the File menu.

It is possible to do adopt multiple files at one time. For details see **Adopt All** on page II-38.

Auto-Compiling

If you modify a procedure window and then activate a nonprocedure window other than a help window, Igor automatically compiles the procedures. If you have a lot of procedures and compiling takes a long time, you may want to turn auto-compiling off.

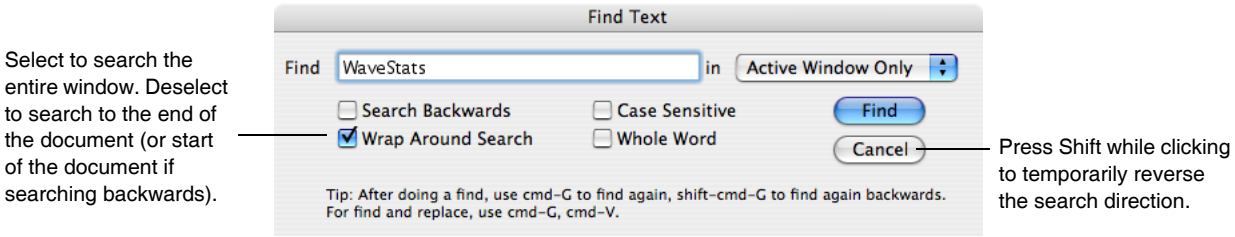
You can do this by deselecting the Auto-compile item in the Macros menu. This item appears only when the procedures need to be compiled (you have modified a procedure file or opened a new one). If you deselect this item, Igor will not auto-compile and compilation will be done only when you click the Compile button or choose Compile from the Macros menu.

Debugging Procedures

Igor includes a symbolic debugger. This is described in **The Debugger** on page IV-184.

Finding Text

You can access the Find Text dialog via the Edit menu or by pressing Command-F (*Macintosh*) or Ctrl+F (*Windows*).



You can search for the next occurrence of a string by selecting the string and pressing Command-Control-H (*Macintosh*) or Ctrl+H (*Windows*) (Find Selection in the Edit menu).

After doing a find, you can search for the same text again by pressing Command-G (*Macintosh*) or Ctrl+G (*Windows*) (Find Same in the Edit menu). You can search for the same text but in the reverse direction by pressing Command-Shift-G (*Macintosh*) or Shift+Ctrl+G (*Windows*).

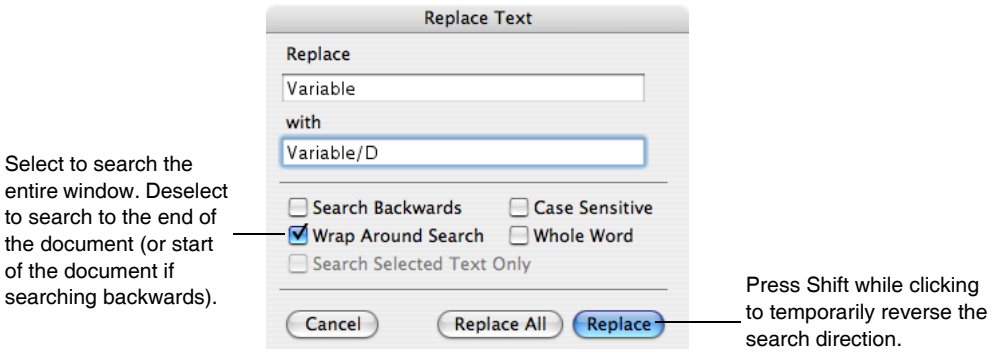
These keyboard shortcuts can be handy. For example, imagine that you are looking at the definition of a function and you want to see where it is used. You can double-click the name of the function to select it and then press Command-Control-H (*Macintosh*) or Ctrl+H (*Windows*) to search for the next occurrence. Then, you can press Command-G (*Macintosh*) or Ctrl+G (*Windows*) to find it again or Command-Shift-G (*Macintosh*) or Ctrl+Shift+G (*Windows*) to go back to the previous occurrence.

You can also perform a Find on multiple help, procedure and notebook windows at one time. See **Finding Text in Multiple Windows** on page II-69.

The Procedures pop-up menu at the bottom of the procedure window provides other ways to find the definition of a procedure in the same or in another procedure file. If you click the pop-up menu, you get a list of all procedures in the active procedure window. If you Option-click (*Macintosh*) or Alt click (*Windows*) on the pop-up menu, you get a list of all procedures in all procedure windows. If you select the name of a procedure and then click the pop-up menu, the first item in the pop-up menu will take you directly to the definition of that procedure, no matter what procedure file it is in.

Replacing Text

You can access the Replace Text dialog via the Edit menu or by pressing Command-R (*Macintosh*) or Ctrl+R (*Windows*).



The Search Selected Text Only option is handy for limiting the replacement to a particular procedure.

Replacing text is not undoable. Save the file before doing a mass replace so you can revert-to-saved if necessary.

Another method for searching and replacing consists of (*Macintosh*) using Command-F (Find) followed by a series of Command-V (Paste) and Command-G (Find Same) or on *Windows*, Ctrl+F followed by a series of Ctrl+V and Ctrl+G.

Printing Procedure Text

Each procedure file has its own page setup record which you can set using the Page Setup item of the File menu. You can use preferences (see **Procedure Window Preferences** on page III-352) to set the page setup record for new procedure windows.

As of Igor Pro 6.20, to make Igor start up faster, each opened help file and procedure file uses a copy of the same page setup record copied from the preferences for plain text notebooks. This change was made to cope with recent Macintosh HP drivers that take a very long time to create a new page setup record. This means that page setup records stored in help and procedure files loaded during launch are ignored.

You can print all or part of a procedure file.

Macintosh: To print all of the file, click so that no text is selected and then use the Print Procedure File item in the File menu. To print part of it, select the text to be printed and then use the Print Procedure Selection item in the File menu.

Windows: Choose File→Print Procedure File and use the Selection radio button in the Print dialog.

Indentation

We use indentation to indicate the structure of a procedure. This is described in **Indentation Conventions** on page IV-22.

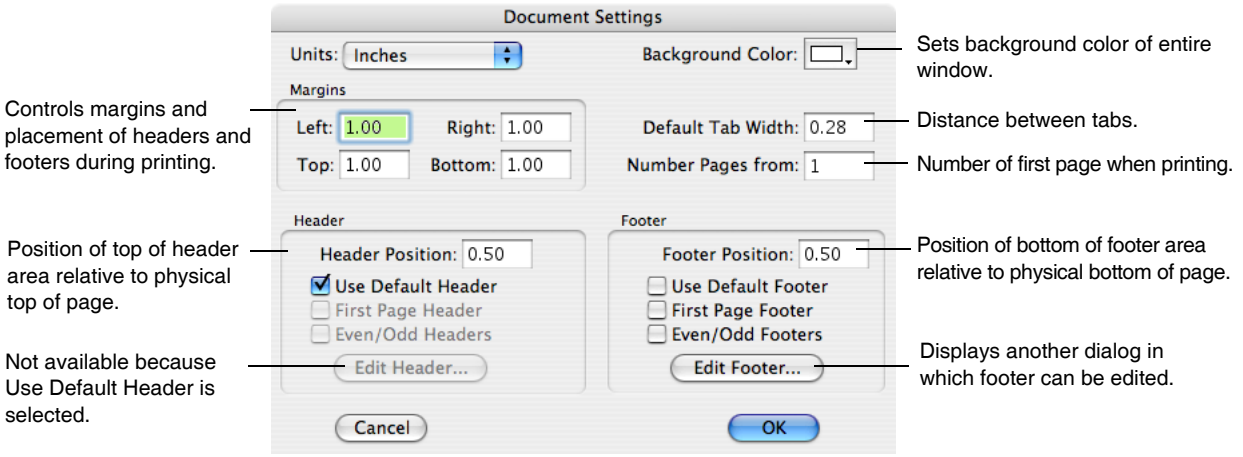
To make it easy to use the indentation conventions, Igor maintains indentation when you press Return or Enter in a procedure window. It automatically inserts enough tabs in the new line to have the same indentation as the previous line.

To indent more, as when going into the body of a loop, press Return or Enter and then Tab. To indent less, as when leaving the body of a loop, press Return or Enter and then Delete. When you don't want to change the level of indentation, just press Return.

Included in the Edit menu for Procedure windows, is the Adjust Indentation item, which adjusts indentation of all selected lines of text to match Igor standards. The Edit menu also contains Indent Left and Indent Right commands that add or remove indentation for all selected lines.

Document Settings

The Document Settings dialog controls settings that affect the procedure window as a whole. You can summon it via the Procedure menu.



Note: On *Windows* there is no way for Igor to store settings for an auxiliary procedure file, which is stored as a plain text file. When you open a procedure file or an experiment containing a procedure file on Windows, Igor uses preferences to set the procedure file's text format (text font, size, style). Thus, text format changes that you make to a procedure file are lost on Windows unless you capture them as your preferred format. The settings for the main procedure window are stored in the experiment file.

Syntax Coloring

The procedure editor colorizes comments, literal strings, flow control, and other function syntax elements. Colors of various elements can be adjusted using the following commands:

Command	Effect
`SetIgorOption colorize,doColorize=<1 or 0>`	Turn all colorize on or off
`SetIgorOption colorize,OpsColorized=<1 or 0>`	Turn operation keyword colorization on or off
`SetIgorOption colorize,BIFuncsColorized=<1 or 0>`	Turn function keyword colorization on or off
`SetIgorOption colorize,keywordColor=(r,g,b)`	Set color for language keywords
`SetIgorOption colorize,commentColor=(r,g,b)`	Set color for comments
`SetIgorOption colorize,stringColor=(r,g,b)`	Set color for strings
`SetIgorOption colorize,operationColor=(r,g,b)`	Set color for operation keywords
`SetIgorOption colorize,functionColor=(r,g,b)`	Set color for built-in function keywords
`SetIgorOption colorize,poundColor=(r,g,b)`	Set color for #keywords such as #pragma

The settings last only for the length of the Igor session. See **SetIgorOption** operation on page V-562.

Values for *r*, *g*, and *b* range from 0 to 65535.

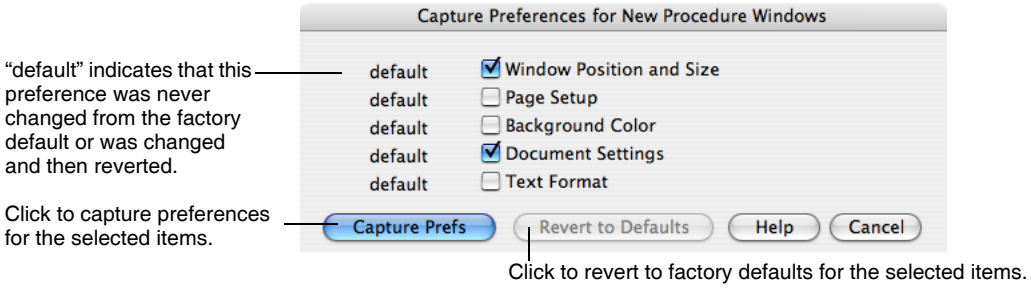
Text Character Settings

You can specify the font, text size, style and color using items in the Procedure menu. Since procedure windows are always plain text windows (as opposed to notebooks, which can be formatted text) these text settings are the same for all characters in the window. On Macintosh, text format settings are stored in the resource fork of the procedure file. On Windows, where there is no resource fork, text format settings are not stored and revert to the preferred settings when a procedure window is opened.

Procedure Window Preferences

The procedure window preferences affect the creation of *new* procedure windows. This includes the creation of auxiliary procedure windows and the initialization of the built-in procedure window that occurs when you create a new experiment.

To set procedure preferences, set the attributes of any procedure window and then use the Capture Procedure Prefs item in the Procedure menu.



To determine the current preference settings, you must create a new procedure window and examine its settings.

Procedure windows each have their own Page Setup values. New procedure windows will have their own copy of the captured (or default) Page Setup values.

Preferences are stored in the Igor Preferences file. See Chapter III-17, **Preferences**, for further information on preferences.

Double and Triple-Clicking

Double-clicking a word conventionally selects the entire word. Igor extends this idea a bit. In addition to supporting double-clicking, if you triple-click in a line of text, it selects the entire line. If you drag after triple-clicking, it extends the selection an entire line at a time.

Matching Characters

Igor includes a handy feature to help you check parenthesized expressions. If you double-click a parenthesis, Igor tries to find a matching parenthesis on the same line of text. If it succeeds, it selects all of the text between the parentheses. If it fails, it beeps. Consider the command

```
wave1 = exp(log(x))
```

If you double-clicked on the first parenthesis, it would select "`log(x)`". If you double-clicked on the last parenthesis, it would beep because there is no matching parenthesis.

If you double-click in-between adjacent parentheses Igor considers this a click on the outside parenthesis.

Igor does matching if you double-click the following characters:

Left and right parentheses	(xxx)
Left and right brackets	[xxx]
Left and right braces	{xxx}
Plain single quotes	'xxx'
Plain double quotes	"xxx"
Typographic single quotes	‘xxx’*
Typographic double quotes	“xxx”*

* No matching is done on two-byte typographic quotes, which are used in Asian fonts.

Code Comments

The Edit menu for procedures contains two items, Commentize and Decommentize, to help you edit and debug your procedure code when you want to comment out large blocks of code, and later, to remove these comments. Commentize inserts comment symbol at the start of each selected line of text. Decommentize deletes any comment symbols found at beginning of each selected line of text.

UTF-16 Files

You can open UTF-16 (two-byte Unicode) text files as procedure windows. Igor does not recognize non-ASCII characters, but does ignore the byte-order mark at the start of the file (BOM) and null bytes contained in UTF-16 text files. If you open a UTF-16 file and then save it from Igor, it will be saved as plain ASCII, not UTF-16, and some information may be lost.

Procedure Window Shortcuts

To view text window keyboard navigation shortcuts, see **Text Window Navigation** on page II-68.

Action	**Shortcut** (*Macintosh*)	**Shortcut** (*Windows*)
To show the built-in procedure window	Press Command-M.	Press Ctrl+M.
To hide the active procedure file and cycle to the next	Press Command-Shift-Option-M.	Press Ctrl+Shift+Alt+M.
To cycle through the open procedure windows	Press Command-Option-M.	Press Ctrl+Alt+M.
To get a contextual menu of commonly-used actions	Press Control and click in the body of the procedure window.	Right-click the body of the procedure window.
To execute commands in a procedure window	Select the commands or click in the line containing the commands and press Control-Return or Control-Enter.	Select the commands or click in the line containing the commands and press Ctrl+Enter.
To insert a template	Type or select the name of an operation or function and press Shift-Help.	Type or select the name of an operation or function and press Ctrl+F1.
	Control-click the name of an operation or function.	Right-click the name of an operation or function.
To get help for an operation or function	Type or select the name of an operation or function and press Shift-Option-Help.	Type or select the name of an operation or function and press Ctrl+Alt+F1.
	Control-click the name of an operation or function.	Right-click the name of an operation or function.
To find a procedure in the active procedure window	Click the Procedures pop-up menu at bottom of the procedure window.	Click the Procedures pop-up menu at bottom of the procedure window.
To find a procedure in any procedure window	Press Option and click the Procedures pop-up menu at bottom of any procedure window.	Press Alt and click the Procedures pop-up menu at bottom of any procedure window.
To find the definition of a procedure when you have selected an invocation of it	Click the Procedures pop-up menu at bottom of the procedure window or press Shift-Option-Help.	Click the Procedures pop-up menu at bottom of the procedure window or press Ctrl+Alt+F1.
To find the same text again	Press Command-G.	Press Ctrl+G.
To find again but in the reverse direction	Press Command-Shift-G.	Press Ctrl+Shift+G.
To find the selected text	Press Command-Control-H.	Press Ctrl+H.
To find the selected text but in the reverse direction	Press Command-Control-Shift-H.	Press Ctrl+Shift+H.

Action	Shortcut (*Macintosh*)	Shortcut (*Windows*)
To find a user-defined menu's procedure	Open any procedure window and press Option while selecting a user-defined menu item.	Open any procedure window and press Alt while selecting the user-defined menu item.
To select a word	Double-click.	Double-click.
To select an entire line	Triple-click.	Triple-click.

Chapter
III-14

Controls and Control Panels

Overview

We use the term *controls* for a number of user-programmable objects that can be employed by Igor programmers to create a graphical user interface for Igor users. We call them *controls* even though some of the objects only display values. The term *widgets* is sometimes used by other application programs, especially on non-Macintosh systems.

Here is a summary of the types of controls available.

Control Type	Control Description
Button	Calls a procedure that the programmer has written.
Chart	Emulates a mechanical chart recorder. Charts can be used to monitor data acquisition processes or to examine a long data record. Programming a chart is quite involved.
CheckBox	Sets an off/on value for use by the programmer's procedures.
CustomControl	Custom control type. Completely specified and modified by the programmer.
GroupBox	An organizational element. Groups controls with a box or line.
ListBox	Lists items for viewing or selecting.
PopupMenu	Used by the user to choose a value for use by the programmer's procedures.
SetVariable	Sets and displays a numeric or string global variable. The user can set the variable by clicking or typing. For numeric variables, the control can include up/down buttons for incrementing/decrementing the value stored in the variable.
Slider	Duplicates the behavior of a mechanical slider. Selects either discrete or continuous values.
TabControl	Selects between groups of controls in complex panels.
TitleBox	An organizational element. Provides explanatory text or message.
ValDisplay	Presents a readout of a numeric expression which usually references a global variable. The readout can be in the form of numeric text or a thermometer bar or both.

The programmer can specify a procedure to be called when the user clicks on or types into a control. This is called the control's *action procedure*. For example, the action procedure for a button may interrogate values in pop-up menu, checkbox, and SetVariable controls and then perform some action.

Control panels are simple windows that contain these controls. These windows have no other purpose. You can also place controls in graph windows and in panel panes embedded into graphs. Controls are not available in any other window type such as tables, notebooks, or layouts. When used in graphs, controls are not considered part of the *presentation* and thus are **not** included when a graph is printed or exported.

Nonprogrammers will want to skim only the Modes of Operation and Using Controls sections, and skip the remainder of the chapter. Igor programmers should study the entire chapter.

Modes of Operation

With respect to controls, there are two modes of operation: one mode to use the control and another to modify it. To see this, choose Show Tools from the Graph or Panel menu. Two icons will appear in the top-left corner window. When the top icon is selected, you are able to use the controls. When the next icon is selected, the draw tool palette appears below the second icon. To modify the control, select the arrow tool from the draw tool palette.

When the top icon is selected or when the icons are hidden, you are in the *use* or *operate* mode. You can momentarily switch to the *modify* or *draw* mode by pressing Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*). Use this to drag or resize a control as well as to double-click it. Double-clicking

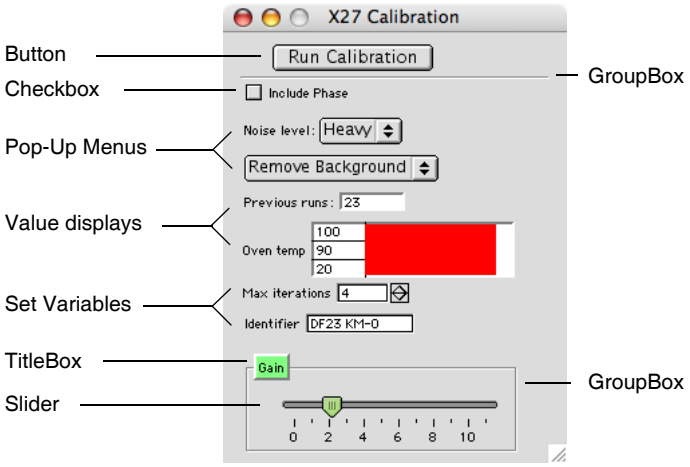
with the Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*) pressed brings up a dialog that you use to modify the control.

You can also switch to modify mode by choosing an item from the Select Control submenu of the Graph or Panel menu.

Important:To enable the Add Controls submenu in the Graph and Panel menus, you must be in modify mode; either by clicking the second icon or by pressing Command-Option (*Macintosh*) or the Ctrl+Alt (*Windows*) while choosing the Add Controls submenu.

Using Controls

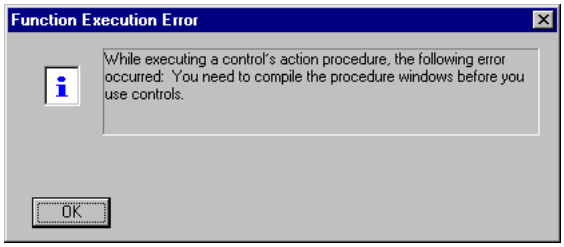
The following panel window illustrates most of the control types.



Buttons

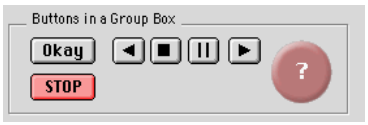
When you click a button, it runs whatever procedure the programmer may have specified.

If nothing happens when you click a button, then there is no procedure assigned to the button. If the procedure window(s) haven't been compiled, clicking a button that has an assigned procedure will produce this dialog:



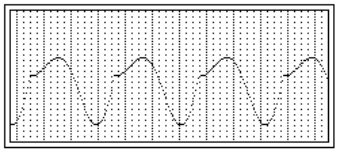
You should choose Compile from the Macros menu to correct this situation. If no error occurs then the button will now be functional.

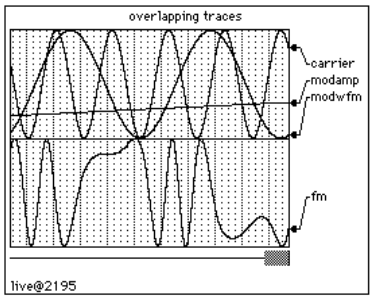
Buttons usually have a rounded appearance, but a programmer can assign a custom picture so that the button can have nearly any appearance.



Charts

Chart controls can be used to emulate a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. Charts can be used to monitor data acquisition processes or to examine a long data record.





Note: Although programming a chart is quite involved, using a chart is actually very easy. However, since most users will never use a chart control, their use is described in **Charts and FIFOs** on page III-369.

Checkboxes

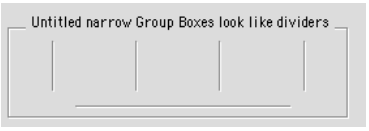
Clicking a checkbox changes its selected state and may run a procedure if the programmer specified one. A checkbox may be connected to a global variable. Checkboxes can be configured to look and behave like radio buttons.

CustomControl

CustomControls are used to create completely new types of controls that are custom-made by the programmer. You can define and control the appearance and all aspects of a custom control's behavior. See **CustomControl** on page III-371 for examples.

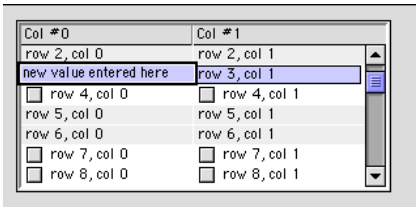
GroupBox

GroupBox controls are organizational or decorative elements. They are used to graphically group sets of controls. They may either draw a box or a separator line and can have optional titles.



ListBox

ListBox controls can present a single or multiple column list of items for viewing or selection. ListBoxes can be configured for a variety of selection modes. Items in the list can be made editable and can be configured as checkboxes.



Pop-Up Menus

These controls come in two forms: one where the current item is shown in the pop-up menu box

and another where there is no current item and a title is shown in the box.

The first form is usually used to choose one of many items while the second is used to run one of many commands.

Pop-up menus can also be configured to act like Igor's color, line style, pattern, or marker pop-up menus; these always show the current item.

Set Variable

Set Variable controls also can take on a number of forms and can display numeric values. Unlike Value Display controls that display the value of an expression, Set Variable controls are connected to individual global variables and can be used to set or change those variables in addition to reading out their current value. Set Variable controls can also be used with global string variables to display or set short one line strings. Set Variable controls are automatically updated whenever their associated variables are changed.

When connected to a numeric variable, these controls can optionally have up or down arrows that increment or decrement the current value of the variable by an amount specified by the programmer. Also, the programmer can set upper and lower limits for the numeric readouts.

New values for both numeric and string variables can be entered by directly typing into the control. If you click the control once you will see a thick border form around the current value.

You can then edit the readout text using the standard techniques including Cut, Copy, and Paste. If you want to discard changes you have made, press Escape. To accept changes, press Return, Enter, or Tab or click anywhere outside of the control. Tab enters the current value and also takes you to the next control if any. Shift-Tab is similar but takes you to the previous control if any.

If the control is connected to a numeric variable and the text you have entered can not be converted to a number then a beep will be emitted when you try to enter the value and no change will be made to the value of the variable. If the value you are trying to enter exceeds the limits set by the programmer then your value will be replaced by the nearest limit.

When a numeric control is selected for editing, the Up and Down Arrow keys on the keyboard act like the up and down buttons on the control.

Changing a value in a Set Variable control may run a procedure if the programmer has specified one.

Set Variable Controls and Data Folders

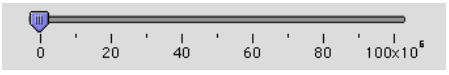
Note: If you are not using Data Folders (described in Chapter II-8, **Data Folders**), you can skip this section.

Set Variable controls remember the data folder in which the variable exists, and continue to function properly when the current data folder is different than the controlled variable. See **Set Variable** on page III-362.

The system variables (K0 through K19) belong to no particular data folder (they are available from any data folder), and there is only *one* copy of these variables. If you create a SetVariable controlling K0 while the current data folder is "aFolder", and another SetVariable controlling K0 while the current data folder is "bFolder", *they are actually controlling the same K0.*

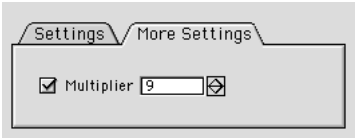
Sliders

Slider controls can be used to graphically select either discrete or continuous values. When used to select discrete values, a slider is similar to a pop-up menu or a set of radio buttons. Sliders can be live, updating a variable or running a procedure as the user drags the slider, or they can be configured to wait until the user finishes before performing any action.



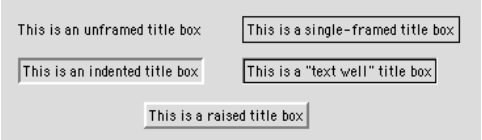
TabControl

TabControls are used to create complex panels containing many more controls than would otherwise fit. When the user clicks on a tab, the programmers procedure runs and hides the previous set of controls while showing the new set.



TitleBox

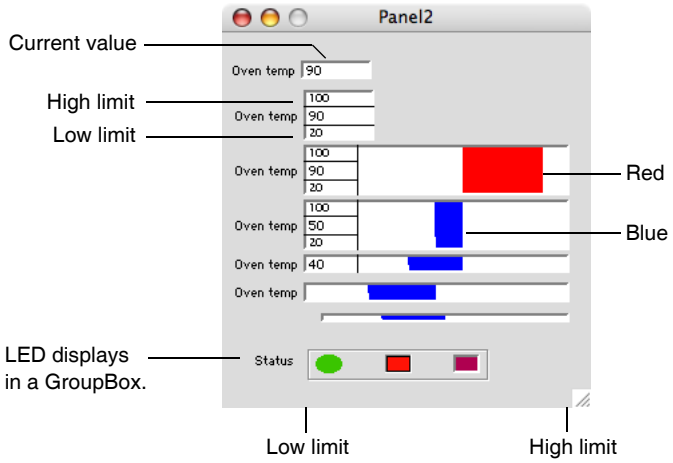
TitleBox controls are mainly decorative elements. They are used provide explanatory text in a control panel. They may also be used to display textual results. The text can be unchanging, or can be the contents of a global string variable. In either case, the user can't inadvertently change the text.



Value Displays

These can take on a number of forms ranging from a simple numeric readout to a thermometer bar. Regardless of the form, value displays are just readouts. There is no interaction with the user. They display the current value of whatever expression the programmer specified. Often this will be just the value of a numeric variable, but it can be any numeric expression including calls to user-defined functions and external functions.

Here is a sampling of the forms that Value Display controls can assume.

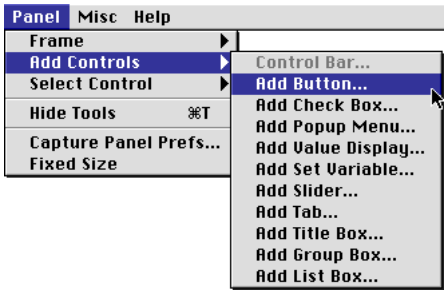


When a thermometer bar is shown, the left edge of the thermometer region represents a low limit set by the programmer while the right edge represents a high limit. The low and high limits appear in some of the above examples. The bar is drawn from a nominal value set by the programmer and will be red if the current value exceeds the nominal value and will be blue if it is less than the nominal value. In the above examples the nominal value is 60. There is no numeric indication of the nominal value. If the nominal value is less than the low limit then the bar will grow from the left to the right. If the nominal value is greater than the high limit then the bar will grow from the right to the left.

If you carefully observe a thermometer bar that is connected to an expression whose value is slowly changing with time you will see that the bar is drawn in a zig-zag fashion. This provides a much finer resolution than if the bar were to be extended or contracted by an entire column of screen pixels at once.

Creating Controls

The ease of creating the various controls varies widely. Anyone capable of writing a simple macro can create Buttons and Checkboxes, but creating Charts and CustomControls requires more expertise. Most controls can be created and modified using dialogs. You will find these dialogs under the Add Controls submenu in the Graph or Panel main menu.



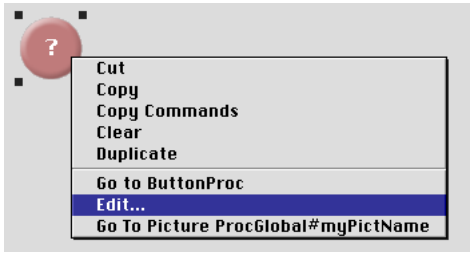
The Add Controls and Select Control menus are disabled until the arrow tool in the toolbar is enabled. (You use the toolbar's arrow tool to position and resize controls.) To do this, choose Show Tools from the Graph or Panel main menu and then click the second icon from the top (in the graph or panel's tool bar).

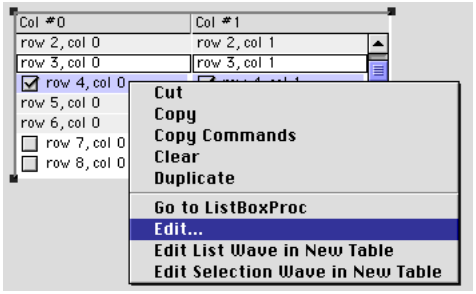
Note: You can also temporarily use the arrow tool without the toolbar showing by pressing Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*). Holding down these keys while selecting from the Graph or Panel menu, you can also choose from the normally-disabled Add Controls and Select Control menus.

When you click a control with the arrow tool, small handles are drawn that allow you to resize the control. Note that some controls can not be resized in this way and some can only be resized in one dimension. You will know this when you try to resize a control and it doesn't budge. You can also use the arrow tool to reposition a control. You can select a control by name with the Select Control submenu in the Graph or Panel menu.

With the arrow tool, you can double-click most controls to get a dialog that modifies or duplicates the control. Charts and CustomControls do not have dialog support.

When you right-click (*Windows*) or Control-click (*Macintosh*) a control, you get a contextual menu that varies depending on the type of control.





You can select multiple controls, mix selections with draw objects and perform operations such as move, cut, copy, paste, delete with undo and align. You can't group buttons or use Send to Back as you can with Igor's draw objects.

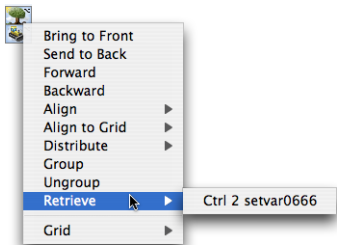
In panels, when you do a Select All it includes all controls and draw objects, but in the case of graphs, only draw objects are selected. This is because draw objects in graphs are used for presentation graphics whereas in panels they are used to construct the user interface.

If you want to copy controls from one window to another, simply use the Edit menu to copy and paste.

Note: If user controls are copied to the Clipboard, then the command and control names are also copied as text. This is handy when modifying controls that have no dialog support.

Hold down Option (*Macintosh*) or Alt (*Windows*) while choosing the Copy command to copy the complete set of procedures that create the copied controls.

If you copy a control from the extreme right side or bottom of a window, it may not be visible when you paste it into a smaller window. Use the smaller window's Retrieve submenu in the Mover menu to make it visible.



General Command Syntax

All of the control commands use the following general syntax:

```
ControlOperation Name [,keyword[=value] [,keyword[=value]]…]
```

Name is the control's name; it must be unique to the window containing the control. If *Name* is not already in use then a new control will be created. If a control with the same name already exists then that control will be modified, so that multiple commands using the same name result in only one control. This is useful for creating controls that require many keywords.

All keywords are optional. Not all controls accept all keywords, and some controls accept a keyword but do not actually use the value(s). The value for a keyword with one control can have a different form than the value for the same keyword used with other controls; the "value" keyword is a prime example of this. See the specific control operation documentation in Chapter V-1, **Igor Reference** for details.

Some controls utilize a format keyword to set a format string. The format string can be any printf style format that expects a single numeric value. Think of the output as being the result of the following command:

```
printf formatString , value_being_displayed
```

See the **printf** operation on page V-499 for a discussion of printf format strings. The maximum length of the format string is 63. The format is used only for controls that display numeric values and only for the principal value within a control (e.g., not used for the limit values for the ValDisplay control)

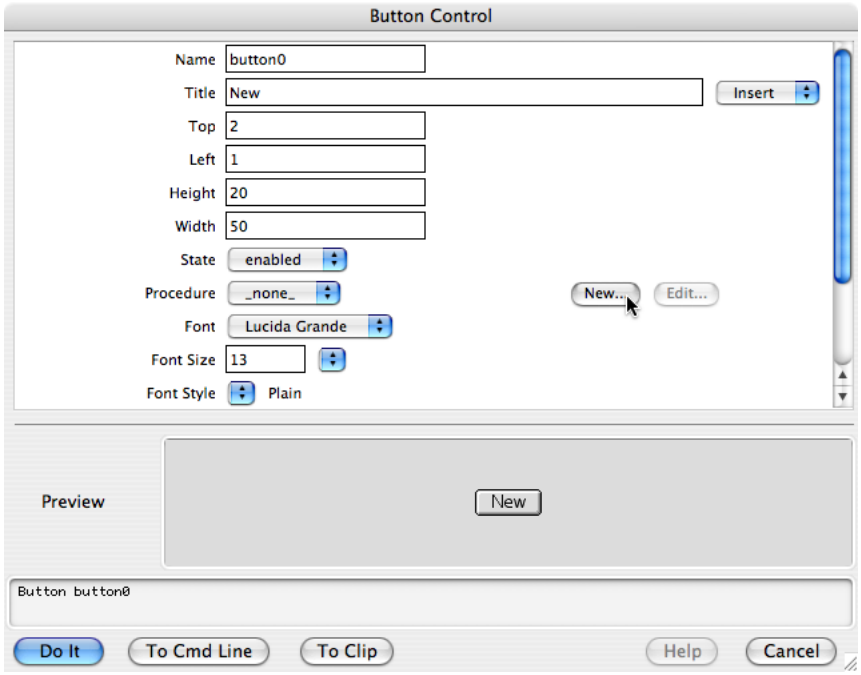
All of the clickable controls can optionally call a user-defined function usually when the user *releases* the mouse button. We use the term *action procedure* for such a function or macro. Each control passes one or more parameters to the action procedure. The dialogs for each control can create a blank user function with the correct parameters.

Read the following section on Buttons for general techniques that apply to all controls. You should also refer to Chapter V-1, **Igor Reference**, for each of the control-related operations and functions.

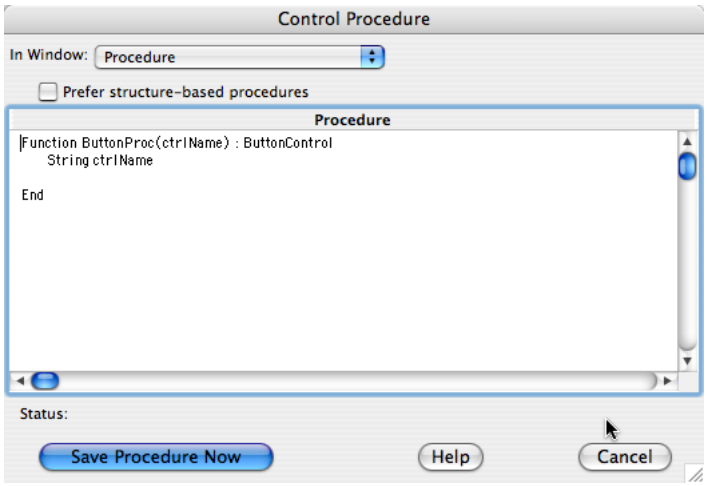
Button

The **Button** operation (page V-38) creates or modifies a rounded-edge or custom button with the title text centered in the button. The default font depends on the operating system, but you can change the font, font size, text color and use annotation-like escape codes (see **About Text Escape Codes** on page III-44). The amount of text does not change the button size, which you can set to what you want. However, the size of a custom button is determined only by the size of its Proc picture.

Here we create a simple button that will just emit a beep when pressed. Start by choosing the Add Button menu item in the Graph or Panel menu to get the Button Control dialog:



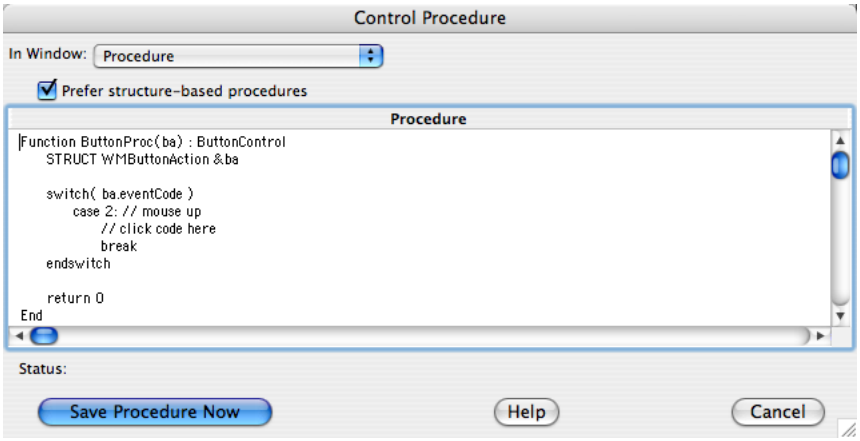
Clicking the procedure's New button brings up a dialog containing a procedure template that you can edit, rename, and save:



The controls can work with procedures using two formats: the "classic" procedure format used in Igor 3 and 4, and the "structure-based" format introduced in Igor 5.

Selecting the "Prefer structure-based procedures" checkbox creates new procedure templates using the structure-based format.

Tip: If you haven't edited a template (or if you delete the template), selecting or deselecting the checkbox will switch the template between the two formats:



Click Help to get help about the type of control the procedure works with. In this example, clicking Help would show the help file for the Button operation, which lists the details about the WMButtonAction structure in the Details section.

All we did in the above dialogs was click the New Procedure button, change the function name from `ButtonProc` to `MyBeepProc` and add the Beep command.

The fact that you can create the action procedure for a control in a dialog may lead you to believe that the procedure is stored with the button. This is not true. The procedure is actually stored in a procedure window. This way you can use the same action procedure for several controls. The parameters which are passed to a given procedure can be used to differentiate the individual controls.

As you can see from the above example, the user defined action procedure that you will need to write for buttons must have the following form:

```
Function ButtonProc(ctrlName) : ButtonControl
   String ctrlName

End
```

Replace `ButtonProc` with a descriptive name and fill in the body of the function. The `ButtonControl` subtype at the end of the function declaration line is optional but highly recommended. If it is present then the function will show up in the pop-up list of available procedures in the Button Control dialog. The other controls have similar subtypes.

It is legal for the action procedure to be written as a Macro (or Proc) rather than as a Function, but Functions are much faster than Macros.

You can use an additional kind of action procedure whose input parameter is a control-specific data structure. The Control Procedure dialog allows you to create either kind of action procedure. For more details, see **Control Structures** on page III-384, the **Button** operation (page V-38), and **Using Structures with Windows and Controls** on page IV-82.

Button Example

Here is how to make a button whose title alternates between Start and Stop.

Enter the following in the Procedure window:

```
Function StartStopButton(ctrlName) : ButtonControl
   String ctrlName

   if( cmpstr(ctrlName,"bStart") == 0 )
      Button $ctrlName,title="Stop",rename=bStop
      MyStartProc()  // or whatever you want when start is pressed
   else
      Button $ctrlName,title="Start",rename=bStart
```

```
      MyStopProc()    // or whatever you want when stop is pressed
   endif
End
```

Additionally, you will also need to create the functions `MyStartProc()` and `MyStopProc()` to actually do something when the button is clicked.

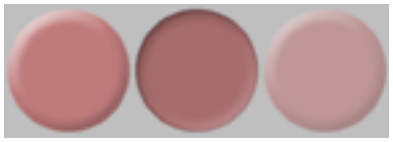
Then create the button in a graph or panel window with:

```
Button bStart,size={50,20},proc=StartStopButton,title="Start"
```

Custom Button Example

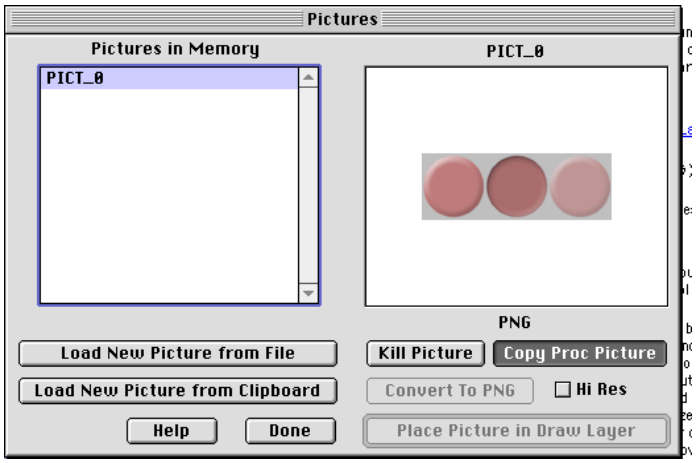
You can create custom buttons by following these steps:

1) Using a graphics-editing program, create a picture that shows the button in it's normal ("relaxed") state, then in the pressed-in state, and then in the disabled state. Each portion of the picture should be the same size:

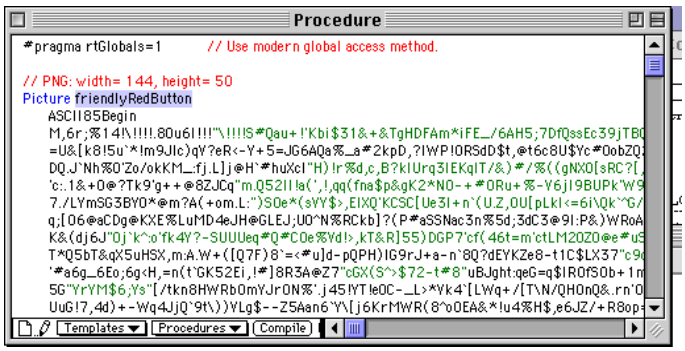


If the button blends into the background it will look better if the buttons are created on the background you will use in the panel. Igor looks at the pixels in the upper left corner, and if they are a light neutral color, Igor will omit those pixels when the button is drawn.

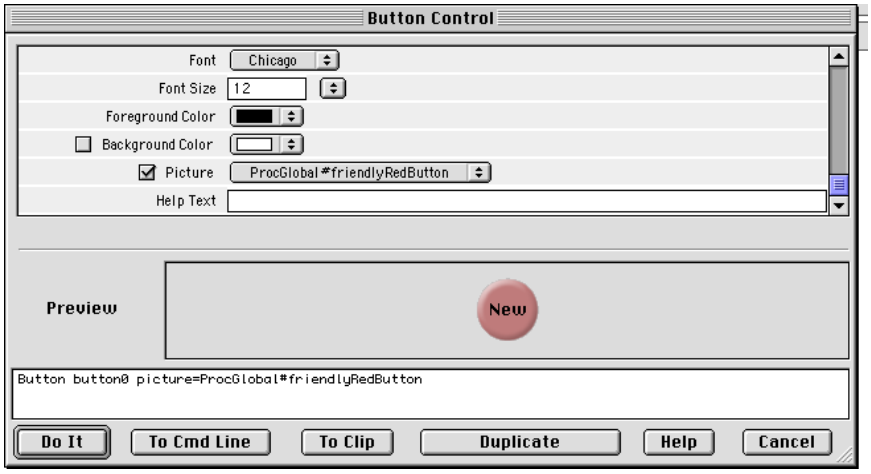
2) Copy the picture to the Clipboard.
3) Switch to Igor and open the Pictures dialog, and click Load New Picture from Clipboard.



4) Click Copy Proc Picture to create Proc Picture text on the Clipboard. Click Done.
5) Select a procedure window, paste the text, and give a suitable name to the picture:



6) Choose this picture in the Button Control dialog:

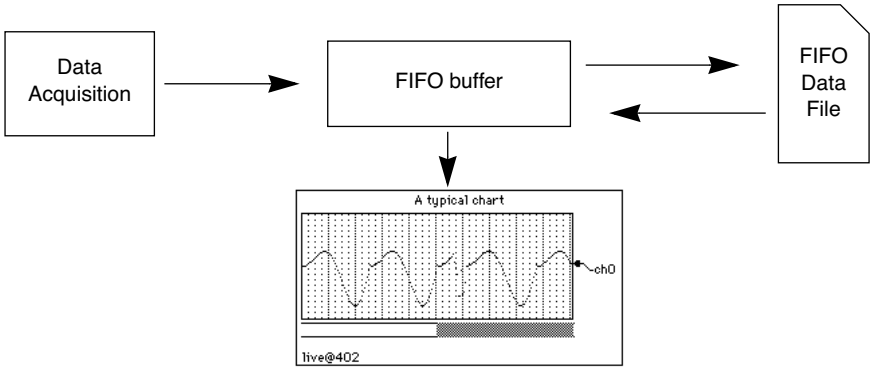


Charts and FIFOs

For further details see **FIFOs and Charts** on page IV-276.

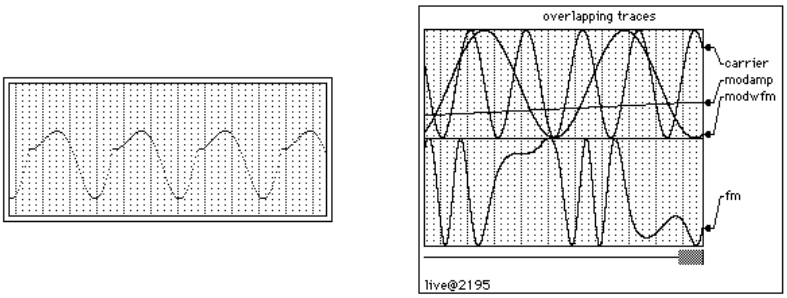
Chart controls can be used to emulate a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. Charts can be used to monitor data acquisition processes or to examine a long data record. Although programming a chart is quite involved, using a chart is very easy.

However, users of the Chart control do need to know the basics of the data acquisition process:



The First-In-First-Out (FIFO) buffer is an invisible Igor component that buffers the data coming from data acquisition hardware and software and also writes the data to a file. The data that is streaming through the FIFO can be observed using a Chart control. When data acquisition is finished the process can be reversed with data coming back out of the file and into the FIFO where it can be reviewed using the Chart. The FIFO file is optional but if missing then all data pushed out the end of the FIFO will be lost.

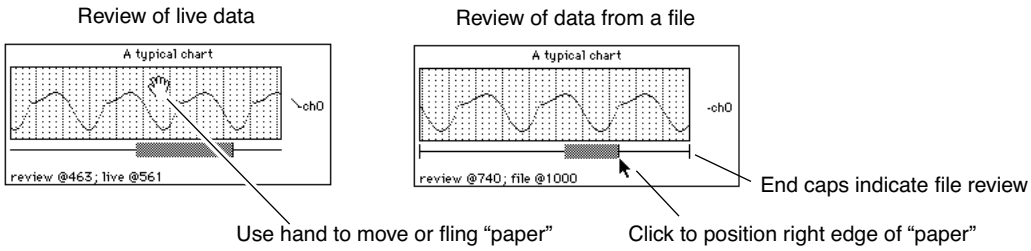
Chart controls can take on quite a number of forms from the simple to the sophisticated:



Charts can operate in two modes — live and review. When a chart is in live mode and data acquisition is in progress, the chart "paper" will scroll by from right to left under the influence of the acquisition process. When in review mode, you are in control of the chart. When you position the mouse over the chart area you will see that the cursor turns into a hand. You can move the chart paper right or left by dragging with the hand. If you give the paper a push it will continue scrolling until it hits the end. You can place the chart in review mode even as data acquisition is in progress by clicking in the paper with the hand cursor. To go back to live mode, give the paper a hard push to the left. When the paper hits the end then the chart will go to into live mode. You can also go back to live mode by clicking anywhere in the margins of the Chart.

Depending on the exact details of the data acquisition hardware and software you may run the risk of corrupting the data if you use review mode while acquisition is in progress. The person that created the hardware and software system you are using should have provided guidelines for the use of review mode during acquisition. In general, if the acquisition process is paced by hardware then it should be OK to use review mode.

In the above chart with lots of bells and whistles you may have noticed the line directly under the scrolling paper area. This line represents the current extent of data while the gray bar represents the data that is being shown in the chart. The right edge of the gray bar represents the right edge of the section of data being shown in the chart window. The above example is shown in live mode. Here are two examples shown in review mode:



While data acquisition is in progress, the horizontal line represents the extent of the data in the FIFO's memory. After acquisition is over then the line includes all of the data in the FIFO's output file (if any).

If you are in review mode while data acquisition is taking place you will notice that the gray bar will indicate the view area is moving even though the paper appears to be motionless. This is because the FIFO is moving out from under the chart. Eventually it will reach a position where the chart display can not be valid since the data it wants to display has been flushed off the end of the FIFO. When this happens the view area will go blank. Because it is very time-consuming for Igor to try to keep the chart updated in this situation your data acquisition rate may suffer.

CheckBox

The **CheckBox** operation (page V-46) creates or modifies a checkbox or a radio button. CheckBox controls automatically size themselves in both height and width. Checkboxes can optionally be connected to a global variable. For information on using checkboxes as radio buttons, see the example in the CheckBox reference section. You can use the font and fsize keywords to adjust the checkbox label.

The user-defined action procedure that you will need to write for CheckBoxes must have the following form:

```
Function CheckProc(ctrlName,checked) : CheckBoxControl
   String ctrlName
   Variable checked

End
```

The checked parameter will be set to the new checkbox value (0 or 1). Checkboxes do not usually need an action procedure since one can read the state of the checkbox with the **ControlInfo** operation (page V-63).

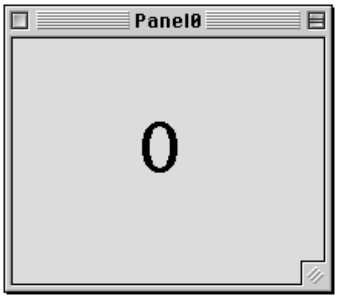
You can create custom checkboxes by following steps similar to those for custom Buttons (see **Custom Button Example** on page III-368), except the picture has six states side-by-side instead of three. The checkbox states are:

Image Order	Control State
Left	Deselected enabled.
	Deselected enabled and clicked down (about to be selected).
	Deselected disabled.
	Selected enabled.
	Selected enabled and clicked down (about to be deselected).
Right	Selected disabled.

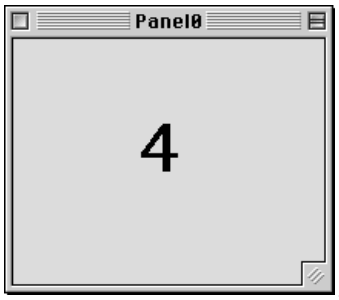
CustomControl

The CustomControl operation creates or modifies a custom control, all aspects of which are completely defined by the programmer. See the **CustomControl** operation on page V-93 for a complete description.

What you can create with a CustomControl can be fairly simple such as this counter that increments when you click on it.



Four clicks later:



.

The following code implements the counter custom control using the `kCCE_frame` event. In the panel, click on the number to increment the counter; also try clicking and then dragging outside the control.

```
static constant kCCE_mouseup= 2
static constant kCCE_frame= 12

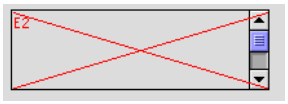
GroupBox

The GroupBox operation creates or modifies a listbox control. See the **GroupBox** operation on page V-238 for a complete description and examples.

ListBox

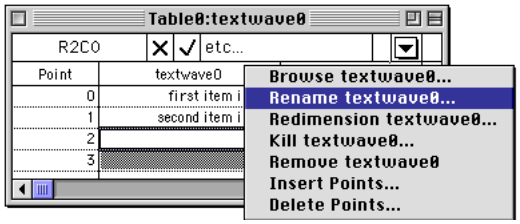
The ListBox operation creates or modifies a listbox control. See the **ListBox** operation on page V-336 for a complete description and examples.

The simplest listbox needs at least one text wave to contain the list items. Without the text wave, a listbox control has no list items.



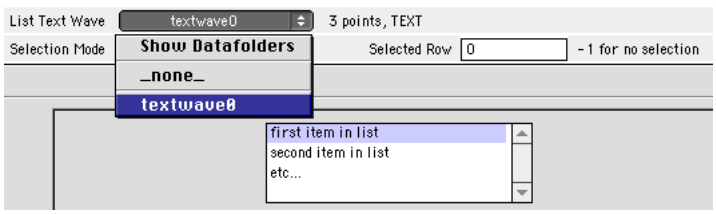
```
ListBox list0 size={200,60},mode=1
```

Create the text wave by opening a table and start typing a nonnumeric first list item (this is to make certain the wave is created as a text wave). You can rename the text wave by Control-clicking (*Macintosh*) or right-clicking (*Windows*) the name and choosing "Rename textwave0".

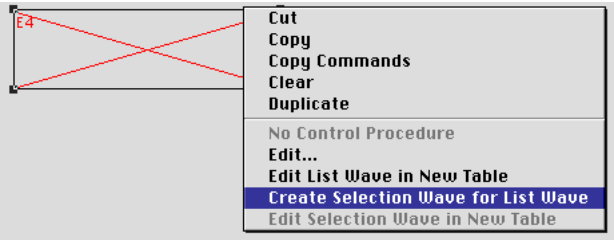


Note: If you want to create a text wave in a particular data folder, set the current data folder first (using the Data Browser in the Data menu).

Then select the wave you created in the ListBox Control dialog as the text wave for the list:



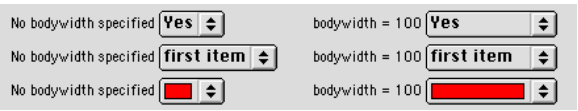
Right-clicking (*Windows*) or Control-clicking (*Macintosh*) a listbox shows a contextual menu for editing the list waves or action procedure, and to create a numeric selection wave (if the ListBox is a multiselection listbox):



PopupMenu

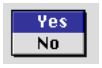
The **PopupMenu** operation (page V-490) creates or modifies a pop-up menu control. Pop-up menus provide a choice of colors, line styles, patterns, markers, or text items:

The control automatically sizes itself as a function of the title or the currently selected menu item. You can specify the bodyWidth keyword to force the body (nontitle portion) of the pop-up menu to be a fixed size. You might do this to get a set of pop-up menus of nicely aligned with equal width. The bodywidth keyword also affects the nontext pop-up menus.



The font and fsize keywords affect only the title of a pop-up menu — the pop-up menu itself uses standard system fonts.

Unlike color, line style, pattern, or marker pop-up menus, text pop-up menu controls can operate in two distinct modes as set by the mode keyword's value.



If the argument to the mode keyword is nonzero then it is considered to be the number of the menu item to be the initial current item *and* displays the current item in the pop-up menu box. This is the *selector mode*. There is often no need for an action procedure since the value of the current item can be read at any time using the **ControlInfo** operation (page V-63).

If mode is zero then the title appears inside the pop-up menu box (hence the name *title-in-box mode*). This mode is generally used to select a command for the action procedure to execute. The current item has no meaning except when the pop-up menu is activated and the selected item (command) is passed to the action procedure.

The menu that pops up when the control is clicked is determined by a string expression that you pass as the argument to the value keyword.

Create the color, line style, pattern or marker pop-up menus by setting the string expression to one of these fixed values: `"*COLORPOP*"`, `"*LINESTYLEPOP*"`, `"*MARKERPOP*"`, or `"*PATTERNPOP*"`.

For text pop-up menus, the string expression must evaluate to a list of items separated by semicolons. For example:

```
PopupMenu name value= "Item 1; Item 2; Item 3"
PopupMenu name value= "_none_;" + WaveList("*",";","")
```

It is possible to apply certain special effects to the menu items, such as disabling an item or marking an item with a check. See **Special Characters in Menu Item Strings** on page IV-114 for details.

It is important to note that the literal text of the string expression is stored with the control rather than the results of the evaluation of the expression. The expression is reevaluated every time the user clicks on the pop-up menu box.

The string expression evaluates as if it were typed on the Command line within the current data folder. Additionally, it is important to specify the data folder containing any string variables, numeric variables, or waves used in the string expression:

```
PopupMenu name value=#"func(root:folder:wave0, root:gVar)"
```

For this reason, the expression can not use numeric or string variables that are local to a procedure since such variables cease to exist when the procedure finishes execution.

To incorporate the value of local variables in the value expression use the **Execute** operation:

```
String str= "\"_none_;first;second;\"" // str contains quotes
Execute "PopupMenu name value=" + str
```

The reason that the evaluation of the menu expression takes place when the user clicks on the menu is to ensure that dynamic menus such as the above WaveList example will reflect the *current* conditions rather than the conditions that were in effect when the PopupMenu control was *created*.

Because of this, the pop-up menu does not automatically update if the value of the string expression changes. You can use the **ControlUpdate** operation (page V-67) to force the pop-up menu to update. Here is an example:

```
NewPanel/N=PanelX
String/G gPopupList="First;Second;Third"
PopupMenu oneOfThree value=gPopupList  // pop-up shows “First”
gPopupList="1;2;3"                     // pop-up is unchanged
ControlUpdate/W=PanelX oneOfThree      // pop-up shows “1”
```

If the value expression can not be evaluated at the time the command is compiled, you can defer the evaluation of the expression by enclosing the value this way:

```
PopupMenu name value= #"pathToNonExistentGlobalString"
```

(the `value=gPopupList` example requires that `gPopupList` exist during compilation.)

If a deferred expression has quotes in it, they need to be “escaped” with backslashes (for a description of this syntax, see **When Dependencies are Updated** on page IV-206):

```
PopupMenu name value= #"\"_none_;\"+UserFunc(\"foo\")"
```

The optional user defined action procedure is called after the user makes a selection from the popup menu. Popup menu procedures have the following form:

```
Function PopMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
   String ctrlName
   Variable popNum
   String popStr

End
```

`popNum` will be the item number, *starting from one*, and `popStr` will be the text of the selected item. For the color pop-up menus the easiest way to determine the selected color is to use the **ControlInfo** operation (page V-63).

Another form of the action procedure uses structures. See **Using Structures with Windows and Controls** on page IV-82.

SetVariable

The **SetVariable** operation (page V-565) creates or modifies a SetVariable control. These controls are tied to numeric or string global variables (or even to one value in a numeric or text wave) and can be used to both view and set these values. When used with numeric variables, up/down arrows that the user can use to increment or decrement the variable will be drawn unless you set the increment value to zero (see the limits keyword).

You can set the width of the control but the height is determined from the font and font size. The width of the readout area is the width of the control less the width of the title and up/down arrows. However, you can use the bodyWidth keyword to specify a fixed width for the body (nontitle) portion of the control.

For example, executing the commands:

```
Variable/G globalVar=99
SetVariable setvar0 size={120,20},frame=1,font="Helvetica", value=globalVar
```

Results in the following SetVariable control: 
To associate a SetVariable control with a variable that is not in the current data folder at the time SetVariable runs, you must use a data folder path:

```
Variable/G root:Packages:ImagePack:globalVar=99
SetVariable setvar0 value=root:Packages:ImagePack:globalVar
```

Unlike PopupMenu controls, SetVariable controls remember the current data folder when the SetVariable command executes. Thus an equivalent set of commands is:

```
SetDataFolder root:Packages:ImagePack
Variable/G globalVar=99
SetVariable setvar0 value=globalVar
```

Also see **Set Variable Controls and Data Folders** on page III-362.

You can control the style of the numeric readout via the format keyword. For example, the string `"%.2d"` will display the value with 2 digits past the decimal point. You should not use the format string to include text in the readout because Igor has to read back the numeric value. You may be able to add suffixes to the readout but prefixes will not work. When used with string variables the format string is not used.

The user defined action procedure that you may need to write for SetVariables must have the following form:

```
Function SetVarProc(ctrlName,varNum,varStr,varName) : SetVariableControl
   String ctrlName
   Variable varNum
   String varStr
   String varName

End
```

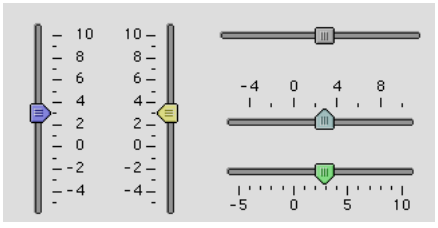
`varName` will be the name of the variable being used. If the variable is a string variable then `varStr` will contain its contents and `varNum` will be set to the results of an attempt to convert the string to a number. If the variable is numeric then `varNum` will contain its contents and `varStr` will be set to the results of a number to string conversion.

Note that when the user presses and holds in the up or down arrows then the value of the variable will be steadily changed by the increment value but your action procedure will not be called until the user releases the mouse button.

Another form of the action procedure uses structures. See **Using Structures with Windows and Controls** on page IV-82.

Slider

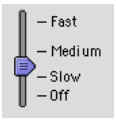
The **Slider** operation (page V-574) creates or modifies a slider control. The control can be used to set the value of a global variable or be used alone to indicate a value to be retrieved with the ControlInfo command. The value is changed by dragging the "thumb" part of the control. The slider can be drawn vertically or horizontally.



There are many options for labelling the numeric range such as setting the number of ticks.

You can also provide custom labels in two waves (one numeric and another providing the corresponding text label):

```
Make/O tickNumbers= {0,25,60,100}
Make/O/T tickLabels= {"Off","Slow","Medium","Fast"}
Slider speed,pos={86,28},size={74,73}
Slider speed,limits={0,100,0},value= 40
Slider speed,userTicks={tickNumbers,tickLabels}
```

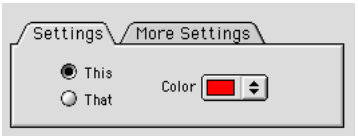


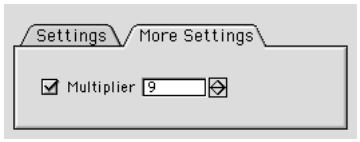
The action procedure for the slider can be used to apply the slider value to a process. The action procedure is called not only when the user moves the thumb, but also when the mouse button clicks down and up on the thumb, and when a procedure modifies the slider's controlled or controlling variable.

See the **Slider** operation on page V-574 for a complete description and more examples.

TabControl

The **TabControl** operation (page V-683) creates or modifies a TabControl control. Tabs are used to group controls into visible and hidden groups.





The tabs are numbered: the first tab is tab 0 and the second is tab 1, etc.

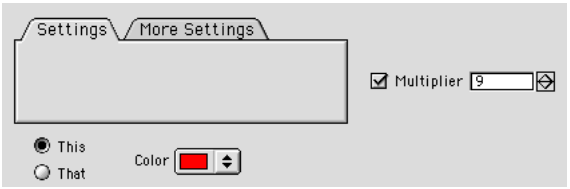
You add tabs to the control by providing additional tab titles:

```
TabControl tb, tabLabel(0)="Settings",tabLabel(1)="More Settings"
```

When you click on a tab, the control's action procedure receives the number of the clicked-on tab.

The showing and hiding of the controls are accomplished by user-written code in the tab control's action procedure. In this example, the "This", "That", and "Color" controls are shown when the "Settings" tab is clicked, and the "Multiplier" checkbox and SetVariable controls are hidden. When the "More Settings" tab is clicked, the action procedure makes opposite occur.

The simplest way to create a tabbed user interface is to create an over-sized panel with all the controls visible and not inside the tab control. Place controls in their approximate positions relative to one another:



By positioning the controls this way you can more easily modify each control until you are satisfied with them. Before you put them into the tab control, get a list of the nontab control names:

```
•Print ControlNameList("" ,"\r", "!tb")      // all but "tb"
thisCheck
thatCheck
colorPop
multCheck
multVar
```

and figure out which tab you want them to be visible in:

Tab 0: Settings	Tab 1: More Settings
thisCheck	multCheck
thatCheck	multVar
colorPop	

Write the action procedure for the tab control to show and hide the controls:

```
Function TabProc(ctrlName,tabNum) : TabControl
   String ctrlName
   Variable tabNum

   Variable isTab0= tabNum==0
   Variable isTab1= tabNum==1

   // note: disable=0 means "show", disable=1 means "hide"
   ModifyControl thisCheck disable= !isTab0  // hide if not Tab 0
   ModifyControl thatCheck disable= !isTab0  // hide if not Tab 0
   ModifyControl colorPop disable= !isTab0   // hide if not Tab 0

   ModifyControl multCheck disable= !isTab1  // hide if not Tab 1
   ModifyControl multVar disable= !isTab1    // hide if not Tab 1
   return 0
End
```

(A more elegant method, which will be important when you have many controls, is to systematically give the controls inside each tab a prefix or suffix that is unique to that tab, such as `tab0_thisCheck`, `tab0_thatCheck`, `tab1_multVar`, and use the ModifyControlList operation to show and hide the controls. See the **ModifyControlList** operation (page V-396) for an example.)

Then assign the action procedure to the tab control with the Tab Control dialog or a command like this:

```
TabControl tb proc=TabProc
```

Click on the tabs to see whether the showing and hiding is working correctly.

When it works correctly, click on one tab and then move the controls that belong inside into the tab area. Click on the next tab and them move that tab's controls into the tab area. You will need to use the operate mode to change the tab by clicking (and thus running the action procedure) and use the modify mode to move the controls. The "temporary selection" shortcut of pressing Command-Option (*Macintosh*) or Ctrl+Alt (*Windows*) is really handy here.

Save a recreation macro for the panel (Windows→Control→Window Control) to record the final control positions in a panel macro. Rewrite the macro as a function that initially creates the panel:

```
Function CreatePanel()
   DoWindow/K TabPanel                     // start over
   NewPanel/N=TabPanel/W=(596,59,874,175) as "Tab Demo Panel"
   TabControl tb,pos={15,19},size={250,80},proc=TabProc
   TabControl tb,tabLabel(0)="Settings"
   TabControl tb,tabLabel(1)="More Settings",value= 0
   CheckBox thisCheck,pos={53,52},size={39,14},title="This"
   CheckBox thisCheck,value= 1,mode=1
```

```
   CheckBox thatCheck,pos={53,72},size={39,14},title="That"
   CheckBox thatCheck,value= 0,mode=1
   PopupMenu colorPop,pos={126,60},size={82,20},title="Color"
   PopupMenu colorPop,mode=1,popColor= (65535,0,0)
   PopupMenu colorPop,value= #"\"*COLORPOP*\""
   CheckBox multCheck,pos={50,60},size={16,14},disable=1
   CheckBox multCheck,title="",value= 1
   SetVariable multVar,pos={69,60},size={120,15},disable=1
   SetVariable multVar,title="Multiplier",value=multiplier
End
```

See the **TabControl** operation on page V-683 for a complete description and examples.

TitleBox

The TitleBox operation creates or modifies a TitleBox control. The control's text can be unchanging, or can be the contents of a global string variable. See the **TitleBox** operation on page V-705 for a complete description and examples.

ValDisplay

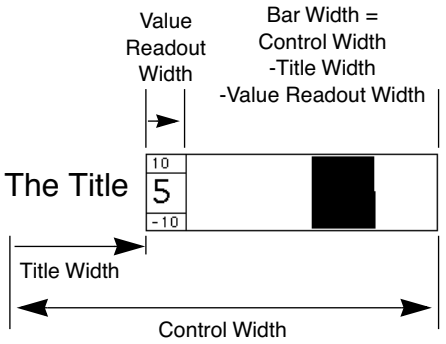
The **ValDisplay** operation (page V-715) creates or modifies a value display control. This is a very flexible and multifaceted control and can range from a simple numeric readout to a thermometer bar or a hybrid of both. A ValDisplay control is "connected" to a numeric expression that you provide as an argument to the value keyword. The display will be automatically updated whenever anything that the numeric expression depends on is changed.

ValDisplay controls evaluate their value expression in the context of the root data folder (see Chapter II-8, **Data Folders**, and **Programming with Data Folders** on page IV-148). To reference a data object that is not in the root, you must use a data folder path, such as "root:Folder1:var1".

Here are a few selected keywords extracted from the **ValDisplay** operation on page V-715:

```
size={width,height}
barmisc={lts, valwidth}
limits={low,high,base}
```

The appearance of the ValDisplay control depends primarily on the *valwidth* and size parameters and the width of the title. However, you can use the bodyWidth keyword to specify a fixed width for the body (non-title) portion of the control. Essentially, space for each element is allocated from left to right, with the title receiving first priority. If the control width hasn't all been used by the title, then the value readout width is the smaller of *valwidth* pixels of room or what is left. If the control width hasn't been used up, the bar is displayed in the remaining control width:



Here are the various major possible forms of ValDisplay controls. Some of these examples modify previous examples; check the names of the ValDisplay controls. For instance, the second bar-only example is a modification of the valdisp1 control created by the first bar-only example.

Numeric Readout Only

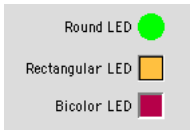
```
// default readout width (1000) is >= default control width (50)
ValDisplay valdisp0 value=K0
```

LED Display

```
// Create the three LED types.
ValDisplay led1,pos={67,17},size={75,20},title="Round LED"
ValDisplay led1,limits={-50,100,0},barmisc={0,0},mode=1
ValDisplay led1,bodyWidth= 20,value= #"K1",zeroColor=(0,65535,0)

ValDisplay led2,pos={38,48},size={104,20},title="Rectangular LED"
ValDisplay led2,frame=5,limits={0,100,0},barmisc={0,0},mode=2
ValDisplay led2,bodyWidth= 20,value= #"K2"
ValDisplay led2,zeroColor= (65535,49157,16385)

ValDisplay led3,pos={60,76},size={82,20},title="Bicolor LED"
ValDisplay led3,limits={-40,100,-100},barmisc={0,0},mode= 2
ValDisplay led3,bodyWidth= 20,value= #"K3"
```

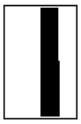


Bar Only

```
// readout width = 0
ValDisplay valdisp1,frame=1,barmisc={12,0},limits={-10,10,0},value=K0
K0= 5                // halfway from base of 0 to high limit of 10.
```

The nice thing about a bar-only ValDisplay is that you can make it 5 to 200 pixels tall whereas with a numeric readout, the height is set by the font sizes of the readout and printed limits.

```
// Set control height= 80
ValDisplay valdisp1, size={50,80}
```



Numeric Readout and Bar

```
// 0 < readout width (50) <  control width (150)
ValDisplay valdisp2 size={150,20},frame=1,limits={-10,10,0}
ValDisplay valdisp2 barmisc={0,50},value=K0  // no limits shown
```

Optional Limits

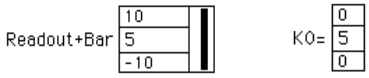
Whenever the numeric readout is visible, the optional limit values may be displayed too.

```
// Set limits font size to 10 points. Readout widths unchanged.
ValDisplay valdisp2 barmisc={10,50}
ValDisplay valdisp0 barmisc={10,1000}
```

Optional Title

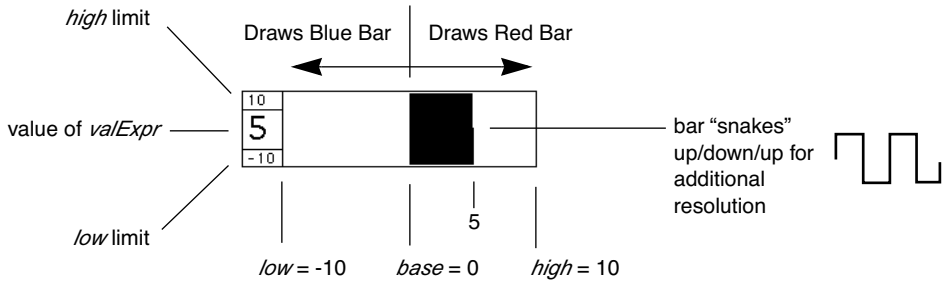
The control title steals horizontal space from the numeric readout and the bar, pushing them to the right. You may need to increase the control width to prevent them from disappearing.

```
// Add titles. Readout widths, control widths unchanged.
ValDisplay valdisp2 title="Readout+Bar"
ValDisplay valdisp0 title="K0="
```



The limits values *low*, *high*, and *base* and the value of *valExpr* control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the *base* value to an ending position determined by the value of *valExpr*, *low* and *high*. *low* corresponds to the left side of the bar, and *high* corresponds to the right. The position that corresponds to the *base* value is linearly interpolated between *low* and *high*.

For example, with *low* = -10, *high*=10, and *base*= 0, a *valExpr* value of 5 will draw from the center of the bar area (0 is centered between -10 and 10) to the right, halfway from the center to the right of the bar area (5 is halfway from 0 to 10):



You can force the control to not draw bars with fractional parts by specifying mode=3.

Killing a Control

You can kill (delete) a control from within a procedure using the **KillControl** operation (page V-321). This might be useful in creating control panels that change their appearance depending on other settings.

You can interactively kill a control by selecting it with the arrow tool or the Select Control submenu and press Delete. Moving a control out of the window does not delete it; you just end up with a control that is offscreen.

Getting Information About a Control

You can use the **ControlInfo** operation (page V-63) to obtain information about a given control. This is useful to obtain the current state of a checkbox or the current setting of a pop-up menu.

Updating a Control

You can use the **ControlUpdate** operation (page V-67) to cause a given control to redraw with its current value. You can use this in a user-defined function or macro after changing the value or appearance of a control and to display the changes before the normal graph or panel update occurs.

Help Text for User-Defined Controls

You can easily add help Igor Tips (*Macintosh*) or context-sensitive/status line help text (*Windows*) for your controls. Each dialog has a button titled Igor Tips (*Macintosh*) or Edit Help (*Windows*) that leads to a subdi-

alog where you can edit the help text. You can also use the command line. You are limited to using a total of 255 characters for your help message. Here is an example:

```
Button button0 title="Beep", help={"This button beeps."}
```

This creates a button with a Macintosh Igor Tip, or under Windows, this text appears as context-sensitive help and in the status line when the mouse passes over the control. The help text that appears on the status line is limited to the first 127 characters of text or the text up to the first line break. The `help={"This button beeps."}` section sets the help text for the button. You can use the help keyword with the Checkbox, PopupMenu, ValDisplay, and SetVariable operations as well as the Button operation.

There is no way to specify help for the individual items in a user-defined pop-up menu.

Modifying a Control

The control operations create a new control if the name parameter doesn't match a control already in the window. The operations modify an existing control if the name does match a control in the window, but generate an error if the control kind doesn't match the operation.

For example, if a panel already has Button control named `button0`, you can modify, say, the disable state for that button with another `Button button0` command:

```
Button button0 disable=1              // hide
```

However, if you use a Checkbox instead of Button, you will get a "button0 is not a Checkbox" error.

You can use the **ModifyControl** operation (page V-395) and **ModifyControlList** operation (page V-396) to modify a control without needing to know what kind of control it is:

```
ModifyControl button0 disable=1      // hide
```

This is really handy when used in conjunction with tab controls.

Disabling and Hiding a Control

All controls support the keyword "disable=*d*" where *d* can be 0 (normal operation), 1 (hidden), or 2 (user input disabled). Charts and ValDisplays do not change appearance when disable=2 because they are read-only.

SetVariables also have the noedit keyword. This appears to be redundant with the disable=2 mode but there is one quasi-important difference: noedit still allows user input via the up or down arrows but disable=2 does not.

Background Color

The background color of Panel windows (see **Control Panels** on page III-389) and the area at the top of a graph as reserved by the **ControlBar** operation (page V-63) is a shade of gray chosen to match the standard Macintosh or Windows system look. This gray is used when the background color is the default pure white where the red, green and blue components are all 65535. Any other color, including not quite pure white, will be honored.

However some controls or portions of controls are drawn by the system and may look out of place if you choose a different background color. The cbRGB keyword is used to set the control background in Panels (**ModifyPanel** operation on page V-419) and Graphs (**ModifyGraph (colors)** operation on page V-415).

Most controls are drawn with a background color that matches the window background color giving the impression of transparency. A few controls are drawn with true transparent labels and no background color is needed.

For special purposes, you can specify a background color for an individual control using the labelBack keyword (see the reference descriptions of the individual controls for further details).

On the Macintosh prior to Igor Pro 4, the background color of controls was white. This matched the window color which was also white. The new technique is somewhat nonbackwards compatible and a few people may prefer the old white on white look. In many cases simply setting the window background to slightly off-white:

```
ModifyGraph cbRGB=(65534,65534,65534)
```

will do the job. In other cases, you may need to specify the background color of individual controls using the labelBack keyword.

On Windows, the background color of the controls themselves is dependent on the current Appearances Settings. Specifically, the background color of controls is set by the 3D Objects color in the Appearance Tab of the Display Properties control panel. You should be aware that any color you choose now may not result in pleasing esthetics when these settings are changed in the future.

On Windows if you do not explicitly set the background color, the standard Windows 3D Objects color is used. This works well with buttons and other standard Windows controls, even when the user changes the 3D Objects color later. You can change the background color to track the 3D Objects color by choosing the current 3D Objects color from the color pop-up palette, or by executing a command to set the background to maximum Macintosh white:

```
ModifyGraph cbRGB=(65535,65535,65535)
ModifyPanel cbRGB=(65535,65535,65535)
```

Control Structures

The action procedure for a control can also use a predefined, built-in structure as a parameter to the function. The control will use this more efficient method whenever the function properly matches the structure prototype for a control, otherwise it will use the "old-style" method.

An action procedure using a structure has the format:

```
Function newActionProcName(CB_Struct)
   STRUCT WMCheckboxAction &CB_Struct
   …
End
```

The names of the various control structures are listed in the next table. You should consult the reference information for each individual control to see what members each control structure contains.

Control Type	Structure Name
Button	**WMButtonAction**
CheckBox	**WMCheckboxAction**
CustomControl	**WMCustomControlAction**
ListBox	**WMListboxAction**
PopupMenu	**WMPopupAction**
SetVariable	**WMSetVariableAction**
Slider	**WMSliderAction**
TabControl	**WMTabControlAction**

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

Control Structure Example

This example illustrates the extended event codes available with a Button control (as well as a application of user data). The function prints various text messages to the History area depending what actions you take while in the button area.

```
Function structureTest()
   NewPanel
   Button b0,proc= NewButtonProc
End

Structure MyButtonInfo
   Int32 mousedown
   Int32 isLeft
EndStructure

Function NewButtonProc(s)
   STRUCT WMButtonAction &s

   STRUCT MyButtonInfo bi
   Variable biChanged= 0

   StructGet/S bi,s.userdata
   if( s.eventCode==1 )
      bi.mousedown= 1
      bi.isLeft= s.mouseLoc.h < (s.ctrlRect.left+s.ctrlRect.right)/2
      biChanged= 1
   elseif( s.eventCode==2 || s.eventCode==3 )
      bi.mousedown= 0
      biChanged= 1
   elseif( s.eventCode==5 )
      print "Enter button"
   elseif( s.eventCode==6 )
      print "Leave button"
   endif

   if( s.eventCode==4 )              //  mousemoved
      if( bi.mousedown )
         if( bi.isLeft )
            printf "L"
         else
            printf "R"
         endif
      else
         printf "*"
      endif
   endif
   if( biChanged )
      StructPut/S bi,s.userdata     // written out to control
   endif

   return 0
End
```

Control Structure eventMod Field

The eventMod field appears in the built-in structure for each type of control. It is a bitfield defined as follows:

EventMod Bit	Meaning
Bit 0	Left mouse button is down.
Bit 1	Shift key is down.
Bit 2	Option (Macintosh) or Alt (Windows) is down.

EventMod Bit	Meaning
Bit 3	Command (Macintosh) or Ctrl (Windows) is down.
Bit 4	Contextual menu click: right-click or Control-click (Macintosh).

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

Control Structure blockReentry Field

The blockReentry field appears in the built-in structure for each type of control. It allows you to prevent Igor from sending your control action procedure another event while you are servicing the first event. This is useful for action procedures that take a long time to service a click event. In such cases you typically do not want to service a second click until you finish servicing the first. This technique prevents an accidental double-click on a button from invoking a time-consuming procedure twice.

You tell Igor that you want to block further events until your action procedure returns by setting the blockReentry field to 1 when your action procedure is called:

```
Function ButtonProc(ba) : ButtonControl
   STRUCT WMButtonAction &ba

   // Tell Igor not to invoke ButtonProc again until this invocation is finished
   ba.blockReentry = 1
   . . .
```

Igor tests this field before invoking your action procedure while it is already running from a previous invocation. You do not need to test this field or reset it to 0 - just set it to 1 to block reentry.

Control Structure blockReentry Advanced Example

This example further illustrates the use of the blockReentry field. It is of interest only to those who want to experiment with this issue.

The ReentryDemoPanel procedure below creates a panel with two buttons. Each button prints a message in the history area when the action procedure receives the "mouse up" message, then pauses for two seconds, and then prints another message in the history before returning. The pause is a stand-in for a procedure that takes a long time.

The top button does not block reentry so, if you click it twice in quick succession, the action procedure is reentered and you get nested messages in the history area.

The bottom button does block reentry so, if you click it twice in quick succession, the action procedure is not reentered.

Because of architectural differences, reentry of the action procedure occurs on Macintosh but not on Windows so on Windows, both buttons behave the same.

```
Function ButtonProc(ba) : ButtonControl
   STRUCT WMButtonAction &ba

   switch( ba.eventCode )
      case 2: // mouse up
         // Block bottom button only
         ba.blockReentry= CmpStr(ba.ctrlName,"Block") == 0
         print "Start button ",ba.ctrlName
         Variable t0= ticks
         do
            DoUpdate
         while(ticks < (t0+120) )
         Print "Finish button",ba.ctrlName
         break
```

```
   endswitch

   return 0
End

Window ReentryDemoPanel() : Panel
   PauseUpdate; Silent 1// building window...
   NewPanel /K=1 /W=(322,55,622,255)
   Button NoBlock,pos={25,10},size={150,20},proc=ButtonProc,title="No Block Reentry"
   Button Block,pos={25,50},size={150,20},proc=ButtonProc,title="Block
Reentry"
End
```

User Data for Controls

You can store arbitrary data with a control using the userdata keyword. You can set user data for the following controls: Button, CheckBox, CustomControl, ListBox, PopupMenu, SetVariable, Slider, and TabControl.

Each control has a primary, unnamed user data that is used by default. You can also store an unlimited number of different user data strings by specifying a name for each different user data string. The name can be anything you desire as long as it is a legal Igor name.

You can retrieve information from the default user data using the **ControlInfo** operation (page V-63), which returns such information in the S_UserData string variable. To retrieve any named user data, you must use the **GetUserData** operation (page V-224).

Although there is no size limit to how much user data you can store, it does have to be generated as part of the recreation macro for the window when experiments are saved. Consequently, huge user data can slow down experiment saving and loading

User data is intended to replace or reduce the usage of global variables.

Control User Data Examples

A simple example of user data with a button:

```
NewPanel
Button b0,userdata="user data for button b0"
Print GetUserData("","b0","")
```

A more complex example using user data for buttons. Copy the following code into the Procedure window of a new experiment and run the `Panel()` macro. Then click on the buttons.

```
Structure mystruct
   Int32 nclicks
   double lastTime
EndStructure

Function ButtonProc(ctrlName) : ButtonControl
   String ctrlName

   STRUCT mystruct s1
   String s= GetUserData("", ctrlName,"")
   if( strlen(s) == 0 )
      print "first click"
   else
      StructGet/S s1,s
      // Warning: Next command is wrapped to fit on the page.
      printf "button %s clicked %d time(s), last click = %s\r",ctrlName, s1.nclicks,
Secs2Date(s1.lastTime, 1 )+" "+Secs2Time(s1.lastTime,1)
   endif
   s1.nclicks += 1
   s1.lastTime= datetime
   StructPut/S s1,s
   Button $ctrlName,userdata= s
End

Window Panel0() : Panel
   PauseUpdate; Silent 1            // building window...
   NewPanel /W=(150,50,493,133)
```

```
    SetDrawLayer UserBack
    Button b0,pos={12,8},size={50,20},proc=ButtonProc,title="Click"
    Button b1,pos={65,8},size={50,20},proc=ButtonProc,title="Click"
    Button b2,pos={119,8},size={50,20},proc=ButtonProc,title="Click"
    Button b3,pos={172,8},size={50,20},proc=ButtonProc,title="Click"
    Button b4,pos={226,8},size={50,20},proc=ButtonProc,title="Click"
EndMacro
```

Action Procedures for Multiple Controls

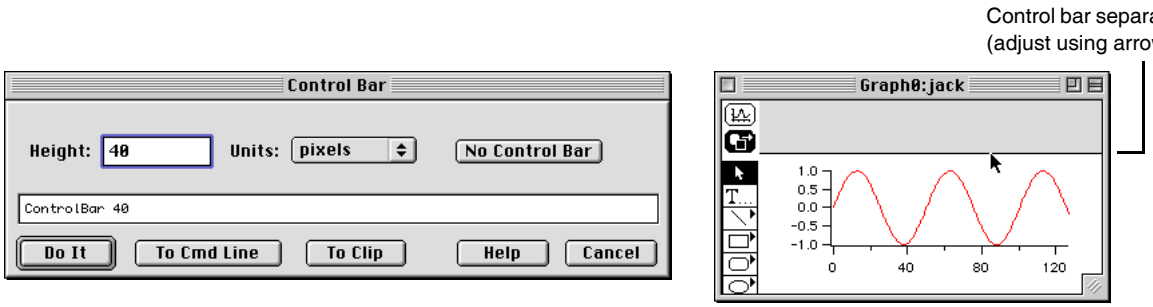
You can use the same action procedure for different controls of the same type (for all the Buttons in one window, for example). The name of the control is passed to the action procedure so that it can know which control was clicked. This is usually the name of the control *in the target/active window*, which is what most control operations assume.

When you call an action procedure from another procedure (rather than because a control was clicked), the name of the control may not be sufficient to identify the control; the window name may also be needed. This must be passed in through a global string. The window name can then be used to specify which window the named control is in by adding win=*winName* to the command, as in:

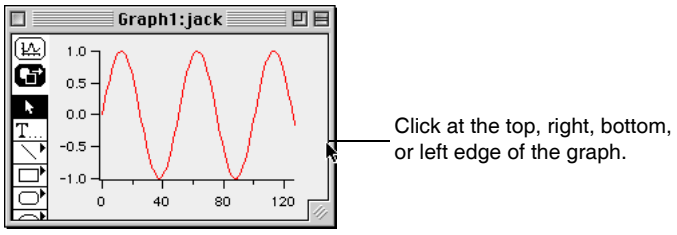
```
Button button0 win=$graphNameStr, title="Hello"
```

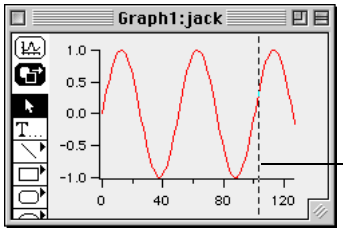
Controls in Graphs

Although controls can be placed anywhere in a graph, you can and should reserve an area just for controls at the edge of a graph window. Controls in graphs operate much more smoothly if they reside in these reserved areas. The **ControlBar** operation (page V-63) or the Control Bar dialog can be used to set the height of a nonembedded control area at the top of the graph.

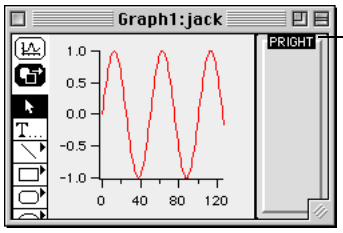


You can also embed a panel in the graph, which gives you more freedom on where to place the controls (see Chapter III-4, **Embedding and Subwindows** for further details and **Embedding into Control Panels** on page III-390 for a different approach). The simplest way to add a panel is to click near the edge of the graph and drag out a control area:

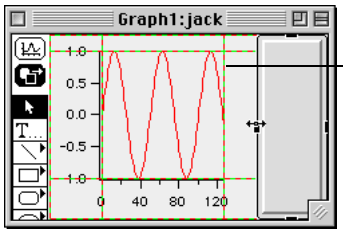




Drag the dashed line to define the inside edge of the embedded panel.



PRIGHT is the name of the resulting embedded panel subwindow. The label disappears in “operate” mode.



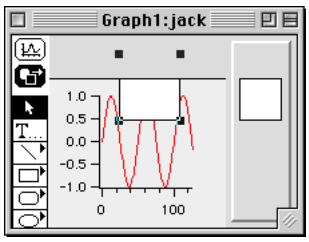
Adjust the position of the embedded window by clicking the subwindow frame and dragging its handles. The dashed lines represent the edges of the plot and graph areas, and the subwindow frame snap and attach to them.

The background color of a control area or embedded panel can be set by clicking the background to exit any subwindow layout mode, and then Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the background and then selecting a color from the contextual menu’s pop-up color palette. See **Background Color** on page III-383 for further details.

The contextual menu adjusts the style of the frame around the panel.

You can use the same contextual menu to remove an embedded panel, leaving only the bare control area underneath. Remove the control area by dragging the inside edge back to the outside edge of the graph.

Drawing Limitations



The drawing tools can not be used in bare control areas of a graph. If you want to create a fancy set of controls with drawing tools, you will have to embed a panel subwindow into the graph.

Updating Problems

You may occasionally run into certain updating problems when you use controls in graphs. One class of update problems occurs when the action procedure for one control changes a variable used by a ValDisplay control in the same graph and also forces the graph to update while the action procedure is being executed. This short-circuits the normal chain of events and results in the ValDisplay not being updated.

You can force the ValDisplay to update using the **ControlUpdate** operation (page V-67). Another solution is to use a control panel instead of a graph.

The ControlUpdate operation can also solve problems in updating pop-up menus. This is described above under **PopupMenu** on page III-375.

Control Panels

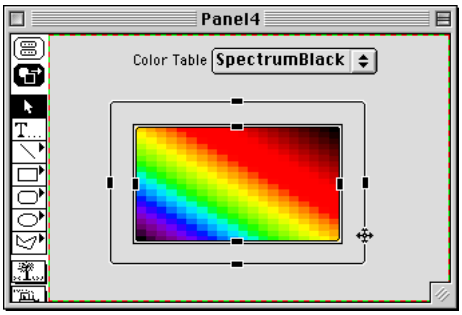
Control panels are windows designed to contain controls. The **NewPanel** operation (page V-440) is used to create a panel.

Drawing tools can be used in panel windows to decorate control panels. Only two drawing layers are provided and both are behind the controls layer. There is probably little reason to distinguish between the user and prog layers since users have no reason to draw in panels.

The Drawing tools can be used in panel windows to decorate control panels. Background color can be set by Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the background and then selecting a color from the pop-up color palette. See **Background Color** on page III-383 for further details.

Embedding into Control Panels

You can embed a graph, table, notebook, or another panel into a control panel window (see Chapter III-4, **Embedding and Subwindows** for further details). You may find this preferable to putting control areas around a graph when you have many controls, or you may embed a graph in order to display an annotation, colorscale, or image plot. Use the contextual menu while in drawing mode to add an embedded window. Click on the frame of the embedded window to adjust the size and position.



You can use a notebook subwindow in a control panel to display status information or to accept lengthy user input. See **Notebooks as Subwindows in Control Panels** on page III-94 for details.

Exterior Subwindows

Exterior subwindows are panels that act like subwindows but live in their own windows attached to a host graph window. The host graph and its exterior subwindows move together and, in general, act as single window. Exterior subwindows have the advantage of not disturbing the host graph and, unlike normal subwindows, are not limited in size by the host graph.

Note: Exterior subwindows must be panels and the only host supported is a graph window.

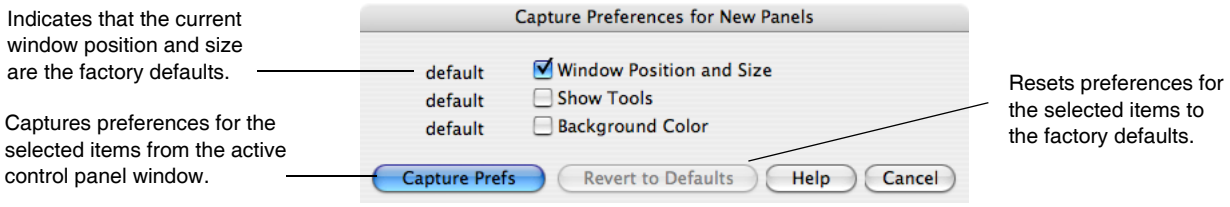
To create an exterior subwindow panel, use **NewPanel** with the /EXT flag in combination with /HOST.

Floating Panels

Floating control panels float above all other windows (except dialogs). To create a floating panel, use **NewPanel** with the /FLT flag.

Control Panel Preferences

Control panel preferences allow you to control what happens when you create a new control panel. To set preferences, create a panel and set it up to your taste. We call this your *prototype* panel. Then choose Capture Panel Prefs from the Panel menu.



Preferences are normally in effect only for *manual* operations, not for automatic operations from Igor procedures. This is discussed in more detail in Chapter III-17, **Preferences**.

When you initially install Igor, all preferences are set to the factory defaults. The dialog indicates which preferences you have changed.

The preferences affect the creation of new panels only.

Selecting the Show Tools category checkbox captures (or reverts) whether or not the drawing tools palette is initially shown or hidden when a new panel is created.

Controls Shortcuts

Action	Shortcut (*Macintosh*)	Shortcut (*Windows*)
To show or hide a panel's or graph's tool palette	Press Command-T.	Press Ctrl+T.
To move or resize a user-defined control without using the tool palette	Press Command-Option and click the control. With Command-Option still pressed, drag or resize it.	Press Ctrl+Alt and click the control. With Ctrl+Alt still pressed, drag or resize it.
To add a user-defined control without using the tool palette	Press Command-Option and choose from the Panel or Graph menu's Add Control submenu.	Press Ctrl+Alt and choose from the Panel or Graph menu's Add Control submenu.
To modify a user-defined control	Press Command-Option and double-click the control. This displays a dialog for modifying all aspects of the control. If the control is already selected, you don't need to press Command-Option.	Press Ctrl+Alt and double-click the control. This displays a dialog for modifying all aspects of the control. If the control is already selected, you don't need to press Ctrl+Alt.
To edit a user-defined control's action procedure	With the panel in modify mode (tools showing, second icon from the top selected) press the Control key and click the control. This displays a contextual menu with a "Go to <action procedure>" item.	With the panel in modify mode (tools showing, second icon from the top selected) right-click the control. This displays a contextual menu with a "Go to <action procedure>" item.
To create an embedded graph or table in the panel	With the panel in modify mode, press the Control key and click the panel background. Choose the subwindow type from the resulting contextual menu's "New" submenu.	With the panel in modify mode, right-click the panel background. Choose the subwindow type from the resulting contextual menu's "New" submenu.
To change an embedded window's border style	With the panel in modify mode, press the Control key and click the embedded window. Choose the border style from the resulting contextual menu's "Frame" and "Style" submenus.	With the panel in modify mode, right-click the embedded window. Choose the border style from the resulting contextual menu's "Frame" and "Style" submenus.
To remove an embedded window	With the panel in modify mode, press the Control key and click the embedded window. Choose the Delete from the resulting contextual menu.	With the panel in modify mode, right-click the embedded window. Choose the Delete from the resulting contextual menu.
To eliminate a control area at the edge of a graph	In modify mode or while pressing Command-Option, click the inside edge of the control area and drag it to the outside edge of the graph.	In modify mode or while pressing Ctrl+Alt, click the inside edge of the control area and drag it to the outside edge of the graph.
To nudge a user-defined control's position	Select the control and press arrow keys. Press Shift to nudge faster.	Select the control and press arrow keys. Press Shift to nudge faster.

Chapter
III-15

Platform-Related Issues

Platform-Related Issues

Igor Pro runs on Macintosh and Windows. This chapter contains information that is platform-specific and also information for people who use Igor on both platforms.

Windows-Specific Issues

On Windows, the name of the Igor program file must be “Igor.exe”, exactly. If you change the name, Igor extensions will not work because they will be unable to find Igor.

If you press Shift while launching Igor, Igor will skip loading extensions. (This feature is mainly of interest to the programmers at WaveMetrics who launch and quit Igor dozens of times a day during development.) If you want to do this on Windows, you should wait until you see Igor’s startup window before pressing the Shift key because Windows has its own interpretation for Shift during launch of a program.

If you save an experiment while a graph, table, layout, panel or notebook window is minimized, when you reopen that experiment, the window will again be minimized. This feature is not supported for any other kinds of windows, including the command window and all procedure windows. Instead, these other types of windows are reopened in their normal size.

Cross-Platform File Compatibility

Version 3.1 was the first version of Igor Pro that ran on Windows as well as Macintosh.

If you plan to use Igor on both platforms, it is a good idea to keep the same folder hierarchy for your Igor Pro files on both platforms. For example, if your Macintosh Igor files are in "hd:Igor Data Files: . . .", then it is best if you put your Windows Igor files in "C:\Igor Data Files\ . . .". Doing this will maximize the chances that Igor can find files referenced from Igor experiment files.

Experiment Files — Working with Earlier Versions

You may occasionally want to send an experiment file to a colleague who has an earlier version of Igor or open it on a computer with an earlier version of Igor.

If you use new features from a particular version of Igor Pro, you may get errors when you open an experiment file in an older version. Usually you can ignore or correct the errors and recover the file.

Crossing Platforms

When crossing from one platform to another, page setups are only partially translated. Igor tries to preserve the page orientation and margins.

When crossing platforms, Igor attempts to do font substitution where necessary. If Igor can not determine an appropriate font it will display the font substitution dialog where you can choose the font.

Platform-specific picture formats are displayed as gray boxes when you attempt to display them on the non-native platform. This includes the Macintosh PICT format and its variants when displayed on Windows and the Windows Metafile and Enhanced Metafile formats when displayed on Macintosh. The EPS, PNG, JPEG, and TIFF formats are platform-independent and are displayed on both platforms.

Transferring Files Using File Transfer Programs

Some transfer programs offer the option of translating file formats as they transfer the program from one computer to another. This translation usually consists of replacing each carriage return character with a carriage return/linefeed pair (Macintosh to Windows) or vice-versa (Windows to Macintosh). This is called a “text mode” transfer, as opposed to a “binary mode” transfer. This translation is appropriate for plain text files only. In Igor, plain text notebooks, procedure files, and Igor Text data files are plain text. All other files are not plain text and will be corrupted if you transfer in text mode. If you get flaky results after transferring a file, transfer it again making sure text mode is off.

If you have a problem opening a binary file after doing a transfer, compare the number of bytes in the file on both computers. If they are not the same, the transfer has corrupted the file.

File Name Extensions, File Types, and Creator Codes

On Windows, the file name extension indicates the nature of a file. When you double-click a file, Windows uses the extension to determine which program to launch. Mac OS 9 used the Mac-specific file type property to determine the nature of the file and the Mac-specific file creator code to determine which program to launch. Mac OS X still supports the file type and creator code properties but de-emphasizes them in favor of the file name extension. For this reason it is best to use the correct file name extension regardless of platform.

The file name extension and corresponding Macintosh file type for Igor Pro files are:

Extension	File Type	What's in the File
.pxp	IGsU	Packed experiment file
.pxt	IGsS	Packed experiment template (stationery)
.uxp	IGSU	Unpacked experiment file
.uxt	IGSS	Unpacked experiment template (stationery)
.ifn	WMT0	Igor formatted notebook (last character is zero)
.txt	TEXT	Igor plain notebook
.ihf	WMT0	Igor help file
.ibw	IGBW	Igor binary data file

The Macintosh creator code for Igor is 'IGR0' (last character is zero).

Experiments and Paths

An Igor experiment sometimes refers to wave, notebook, or procedure files that are stored separate from the experiment file itself. This is discussed under **References to Files and Folders** on page II-37. In this case, Igor creates a symbolic path that points to the folder containing the referenced file. It writes a **NewPath** command in the experiment file to recreate the symbolic path when the experiment is opened. When you move the experiment to another computer or to another platform, this path may not be valid. However, Igor goes to great lengths to find the folder, if possible.

Igor stores the path to the folder containing the file as a relative path, relative to the experiment file, if possible. This means that Igor will be able to find the folder, even on another computer, if the folder's location in the disk hierarchy is the same on both computers. You can minimize problems by using the same disk hierarchy on both computers.

If the folder is not on the same volume as the experiment file, then Igor can not use a relative path and must use an absolute path. Absolute paths cause problems because, although your disk hierarchy may be the same on both computers, often the name of the root volume will be different. For example, on the Macintosh your hard disk may be named "hd" while on Windows it may be named "C:". If Igor is unable to find a folder that is referenced by a full path, it looks for the folder in the same place in the hierarchy, but on the root volume containing the experiment file. If this fails, it looks for the folder in the same place in the hierarchy, but on the root volume containing the Igor application file. Also, if the path points inside the Igor Pro Folder, then Igor looks for the folder in the same place in the hierarchy, but inside the Igor Pro Folder containing the Igor application file.

If all of these methods fail, Igor displays a dialog asking you to locate the folder.

Picture Compatibility

Igor displays pictures in graphs, page layouts, control panels and notebooks. The pictures are stored in the Pictures collection (Misc→Pictures) and in notebooks. Graphs, page layouts and control panels reference pictures stored in the Pictures collection while notebooks store private copies of pictures.

This table shows the graphic formats that Igor can use to store pictures:

Format	How To Create	Notes
PICT	Paste or use Misc→Pictures	Macintosh only
PDF	Paste or use Misc→Pictures	Macintosh only
EMF (Enhanced Metafile)	Paste or use Misc→Pictures	Windows only
BMP (bitmap)	Use Misc→Pictures	Windows Only. BMP also called DIB (device-independent bitmap).
PNG (Portable Network Graphics)	Use Misc→Pictures	Cross-platform bitmap format
JPEG	Use Misc→Pictures	Cross-platform bitmap format
TIFF (Tagged Image File Format)	Use Misc→Pictures	Cross-platform bitmap format
EPS (Encapsulated PostScript)	Use Misc→Pictures	High resolution vector format. Requires PostScript printer. A screen preview is displayed on screen.

PICT was the standard format for Mac OS 9 graphics but has been supplanted by PDF on Mac OS X. EMF is the standard format for Windows graphics. PICT, PDF, EMF and BMP are platform-dependent and will display as gray boxes if you move the Igor experiment to the other platform. The other formats are platform-independent.

Although Igor does not display nonnative graphic formats, it does preserve them. For example, you can create an experiment on Macintosh and paste a Macintosh PDF into a page layout, graph, or notebook window. If you save the experiment and open it on Windows, the PDF will be displayed as a gray box. You can now paste a Windows metafile into the page layout, graph, or notebook window. If you save the experiment and open it on Macintosh, the Window metafile will be displayed as a gray box but the PDF will be displayed correctly. If you now save and open the experiment on Windows again, and the Windows metafile will be displayed correctly.

If you want PDF, PICT, EMF, or BMP/DIB pictures to be displayed correctly on both platforms, you must convert the pictures to PNG. To convert to PNG, use the Pictures dialog (Misc menu) for pictures in graphs and page layouts, or for pictures in notebooks, use the Special submenu in the Notebook menu.

Note: Converting a picture to PNG makes it a bitmap format and may degrade resolution. This is fine for graphics intended to be viewed on the screen but not for graphics intended to be printed at high resolution. You can convert to a high resolution PNG without losing much picture quality. However, this takes a lot of memory during the conversion and when the PNG is displayed. Because PNGs are compressed, they usually do not require excessive disk space when saved.

The ability to store pictures in JPEG, TIFF and EPS formats was added in Igor Pro 5. If you create an experiment with pictures in these formats, they will display as gray boxes if opened in older versions of Igor.

Prior to version 3.1, Igor stored graph and page layout pictures on the Macintosh in the experiment file's resource fork. When you transfer a file created by an Igor version older than 3.1 from the Macintosh to a PC, the resource fork is lost and Igor will display a placeholder rectangle in place of the picture.

Page Setup Compatibility

Page setup records store information regarding the size and orientation of the page. Page setups contain platform- and printer-dependent data. They are most important in regards to page layout windows but also affect printing of other kinds of windows.

On Macintosh, Igor stores page setups in experiment files, notebook files, and procedure files. In each experiment file, Igor stores a separate page setup for each page layout, notebook, and procedure window, and stores a single page setup for all graphs and single page setup for all tables.

On Windows, Igor stores page setups the same as on Macintosh except that it does not store page setups in plain notebook or procedure files. This is true whether the file is embedded in a packed experiment file or is a stand-alone file. When you open a plain notebook or procedure file on Windows, Igor creates a new page setup record by copying the preferred page setup record as set by the Capture Notebook Prefs or Capture Procedure Prefs dialogs.

When you transfer an experiment from one platform to another, page setup records are only partially preserved. Igor attempts to preserve the page orientation and margins.

Prior to version 3.1, Igor stored page setup records on the Macintosh in the experiment file's resource fork. When you transfer a file created by an Igor version older than 3.1 from from the Macintosh to a PC, the resource fork is lost and Igor has no way to know the orientation of the page setups. Therefore, when opening one of these old Macintosh experiment files on Windows, any page layouts in the experiment will use the page setup that you captured using the Capture Layout Prefs dialog or a default page setup if you have not captured a preferred page setup.

Pre-Carbon Page Setup Records

Carbon is a set of routines that Apple created for the transition from Macintosh OS 9 to OS X. The page setup record now used by the Macintosh operating system is called a Carbon page setup record. Prior to that the operating system used a different type of page setup record which we will call an "old Macintosh page setup record."

Experiments saved on Macintosh by pre-Carbon versions of Igor Pro (prior to version 4.05A) contain old page setup records. When you open one of these experiments under OS X, the old page setup record is passed to a system routine that is supposed to convert it to a Carbon page setup record. This usually works correctly but sometimes it corrupts the page setup record. The corruption usually appears as a nonsensical scaling value in the Page Setup dialog for the affected window. If the window is a page layout window, this results in a page that is grossly too small or too big. You can usually fix it by entering 100% for the scaling value in the page setup dialog.

Igor Pro 6 attempts to detect and fix this corruption if the scaling value is less than 50% or greater than 200%. It repairs the page setup record by replacing it with a new default page setup record and then sets the orientation of the new page setup record to match the orientation of the old record. All other properties, such as the scaling, of the old page setup record are lost.

If corruption occurs and the automatic repair is not successful, you can use the **SetIgorOption** operation (see page V-562) to control the old page setup record conversion. The command format is:

```
SetIgorOption RepairOldPageSetups = val
```

The parameter *val* is one of the following:

val	Effect
0	Never repair old page setup records.
1	Repair if the old page setup appears corrupted (default).
2	Always repair old page setup records.
3	Always present a page setup dialog.
4	Always repair and then present a page setup dialog.

The effect of SetIgorOption lasts only until you quit Igor.

File System Issues

This section discusses file system issues that you need to take into account if you use Igor on both Macintosh and Windows.

File and Folder Names

On Windows, the following characters are illegal in file and folder names: backslash (\), forward slash (/), colon (:), asterisk (*), question mark (?), double-quote ("), left angle bracket (<), right angle bracket (>), vertical bar (|). On Macintosh, the only illegal character is colon.

This means, for example, that you can not create a file with a name like "Data 1/23/98" on Windows. You can create a file with this name on Macintosh. If you write an Igor procedure that generates a file name like this, it will run on Macintosh but fail on Windows.

Therefore, if you are concerned about cross-platform compatibility, you must not use any of the Windows illegal characters in a file or folder name, even if you are running on Macintosh. Furthermore, you should not use "high ASCII" characters (see **Character Set Compatibility** on page III-401), because they don't translate across platforms. Also, don't use period except before a file name extension.

Prior to Igor Pro 6.1, the Macintosh version of Igor could not handle file or folder names exceeding 31 characters. Igor Pro 6.1 and later support long file names (up to 255 characters) on Macintosh as well as Windows. Most WaveMetrics XOPs now also support long file names on Macintosh. However XOP file names are still limited to 31 characters plus the ".xop" extension.

The following Igor Pro features will not work with long file names on Mac OS X because Igor calls Apple routines that do not support long file names for these features:

NewMovie
ImageSave when using QuickTime
ImageLoad when using QuickTime

File and folder names in Windows can theoretically be up to 255 characters in length. Because of some limitations in Windows and also in Igor, you will encounter errors if you use file names that long. However, both Igor and Windows are capable of dealing with file names up to about 250 characters in length. It is unlikely that you will approach this limit.

An exception to this is that Igor limits names of XOP files to 31 characters, plus the ".xop" extension. Igor will not recognize an XOP file with a longer name.

Paths in Windows are limited to 259 characters in length. Neither Windows nor Igor can deal with a path that exceeds this limit. For example, if you create a directory with a 250 character name and try to create a file with a 15 character name, neither Windows nor Igor will permit this.

This boils down to the following: Feel free to use long file and directory names, but expect to see errors if you use outrageously long names or if you have directories so deeply nested that paths approach the theoretical limit.

Path Separators

The Macintosh file system uses a colon to separate elements in a file path. For example:

```
hd:Igor Pro Folder:Examples:Sample Graphs:Contour Demo.pxp
```

The Windows file system uses a backslash to separate elements in a file path. For example:

```
C:\Igor Pro Folder\Examples\Sample Graphs:Contour Demo.pxp
```

Some Igor operations (e.g., LoadWave) allow you to enter file paths. Igor accepts Macintosh-style or Windows-style paths regardless of the platform on which you are running.

Note: Igor uses the backslash character as an escape character in literal strings. This can cause problems when using Windows-style paths.

For example, the following command creates a textbox with two lines of text. "\r" is an escape code inserts a carriage return character:

```
Textbox "This is line 1.\rThis is line 2."
```

Because Igor interprets a backslash as an escape character, the following command will not execute properly:

```
LoadWave "C:\Data Files\really good data.ibw"
```

Instead of loading a file named "really good data.ibw", Igor would try to load a file named "Data Files<CR>eally good data.ibw", where <CR> represents the carriage return character. This happens because Igor interprets "\r" in literal strings to mean carriage return.

To solve this problem, you must use "\\" instead of "\" in a file path. Igor will correctly execute the following:

```
LoadWave "C:\\Data Files\\really good data.ibw"
```

This works because Igor interprets "\\" as an escape sequence that means "insert a backslash character here".

Another solution to this problem is to use a Macintosh-style path, even on Windows:

```
LoadWave "C:Data Files:really good data.ibw"
```

Igor will convert the Macintosh-style path to a Windows-style path before using it. This avoids the backslash ambiguity.

For a complete list of escape sequences, see **Escape Characters in Strings** on page IV-13.

If you are writing procedures that need to extract sections of file paths or otherwise manipulate file paths, the **ParseFilePath** function on page V-472 may come in handy.

UNC Paths

"UNC" stands for "Universal Naming Convention". This is a Windows convention for identifying resources on a network. One type of network resource is a shared directory. Consequently, when running under Windows, in order to reference a network directory from an Igor command, you need to use a UNC path.

The format of a UNC path that points to a file in a folder on a shared server volume or directory is:

```
"\\server\share\directory\filename"
```

"server" is the name of the file server and "share" is the name of the top-level shared volume or directory on that server.

Because Igor treats a backslash as an escape character, in order to reference this from an Igor command, you would have to write:

```
"\\\\server\\share\\directory\\filename"
```

As described in the preceding section, you could also use Macintosh path syntax by using a colon in place of two backslashes. However, you can not do this for the "\\server\share" part of the path. Thus, using Macintosh syntax, you would write:

```
"\\\\server\\share:directory:filename"
```

Unix Paths

Unix paths use the forward slash character as a path separator. Igor does not recognize Unix paths. Use Macintosh paths instead.

FlushFileBuffers

On Windows, by default Igor calls the Windows FlushFileBuffers routine before closing a file. FlushFileBuffers flushes data cached in a hard drive's circuitry for the file being closed, ensuring that the data is written to disk. This guarantees the file's integrity in the event of a power failure.

When writing a lot of small files one right after another, for example when saving an unpacked experiment with a very large number of waves or data folders, calling FlushFileBuffers can adversely affect perfor-

mance. In this case, you can use SetIgorOption to disable calling FlushFileBuffers. This is rarely necessary and should be done only in the circumstances described in this paragraph.

To turn FlushFileBuffers off execute:

```
SetIgorOption UseFlushFileBuffers=0                // Turn off
```

To turn FlushFileBuffers on execute:

```
SetIgorOption UseFlushFileBuffers=1                // Turn on (default)
```

To query the state execute:

```
SetIgorOption UseFlushFileBuffers=?; Print V_Flag  // Query
```

This does nothing on Macintosh.

SetIgorOption is usually called from the command line. It can not be executed from a user-defined function. It's effect lasts until Igor quits.

Keyboard and Mouse Usage

This section describes how keyboard and mouse usage differs on Macintosh versus Windows. It is intended to help Igor users more easily adapt when switching platforms.

There are three main differences between Macintosh and Windows input mechanisms:

1. The Macintosh mouse may have one button and the Windows mouse has two.
2. The Macintosh keyboard has four modifier keys (Shift, Command, Option, Control) while the Windows keyboard has three (Shift, Ctrl, Alt).
3. The Macintosh keyboard has Return and an Enter keys while the Windows keyboard (usually) has two Enter keys.

For the most part, Igor maps between Macintosh and Windows input as follows:

Macintosh	Windows
Shift	Shift
Command	Ctrl
Option	Alt
Control	<not mapped>

Macintosh	Windows
Return	Enter
Enter	Enter
Control-click	Right-click

There are a few exceptions to this mapping. For example, Option-Tab enters a tab into a text wave in a table. Alt-Tab does not do this on Windows because Alt-Tab is reserved by the Windows operating system.

In notebooks, procedure windows and help windows, pressing Control-Return or Control-Enter executes the selected text or, if there is no selection, to execute the line of text containing the caret.

Command Window Input

This table compares command window mouse actions:

Action	Macintosh	Windows
Copy history selection to command line	Option-click	Alt+click
Copy history to command and start execution	Command-Option-click	Ctrl+Alt+click
Invoke contextual menu	Control-click	Right-click

You can quickly move the command window (or any built-in Igor window) to its preferred position. On Macintosh, press Option and click the zoom button. On Windows, press Alt and click the maximize button.

Other Input Issues

The accelerators (keyboard shortcuts) for Indent Left and Indent Right in the Edit menu are Command-[and Command-] on Macintosh but are Ctrl+Shift+L and Ctrl+Shift+L R on Windows. This is because Windows does not allow using Ctrl+[or Ctrl+] as an accelerator.

Here are some shortcuts related to the Igor help system:

Action	Macintosh	Windows
Invoke Igor Help Browser	Help	F1
Insert operation or function template	Shift-Help	Ctrl+F1
Go to help for operation or function	Shift-Option-Help	Ctrl+Alt+F1

Cross-Platform Text and Fonts

Character Set Compatibility

The Macintosh and Windows character encodings are the same for the common characters, such as upper and lower case letters, numbers and common punctuation. These are sometimes called the "low ASCII" characters because they have ASCII codes below 128 and appear in the first half of the ASCII character encoding table. The remaining characters, such as accented vowels, bullets and other symbols, are called "high ASCII" characters. The encoding for high ASCII characters is different on the Macintosh and Windows. For example, the character code for a bullet on the Macintosh is the character code for a yen symbol on Windows.

In most cases, Igor does an automatic translation to compensate for these encoding differences. For example, when Igor opens a formatted notebook file or a packed experiment file containing notebooks and procedures, Igor automatically translates. There are some characters for which no translation is possible because the characters are missing from one platform or the other. For example, the Macintosh has a "Š" character but Windows does not. For these characters, Igor does not do any translation. The character will appear incorrect on the nonoriginating platform but will appear correct if the file is moved back to the originating platform.

For some fonts, this translation causes a problem, because the fonts do not use the normal character encodings. Symbol font is an example. It has the same encoding on both platforms and therefore Igor does not do any translation.

When Igor opens a plain text notebook or a procedure file that is a stand-alone file (i.e., is not stored in a packed experiment file) it has no way to know which platform the file came from and therefore can not do character translation. This may result in funny characters appearing, such as a yen symbol where you expect a bullet symbol. If you use such characters in procedure files, this problem may cause errors when you compile or execute the procedures. The only solution is to avoid using high ASCII characters in plain text files.

Like the Symbol font, Asian fonts use the same character encoding on Macintosh and Windows and so Igor does not translate text governed by an Asian font. When opening an experiment using Asian text, it is

important that your preferred procedure file font be an Asian font. This is the factory default if you are running on an Asian version of the Macintosh or Windows operating system. This is important because Igor uses the preferred procedure file font in cases where it has no other way to determine which font should be used for the file, such as when you open a stand-alone procedure file on Macintosh or any procedure file (even packed into an experiment file) on Windows.

Text Styles

The outline and shadow text styles are available on Macintosh only. On Windows, these styles have no effect and Igor disables Outline and Shadow items in menus and Outline and Shadow checkboxes in dialogs.

Carriage Returns and Linefeeds

The character or character pattern that marks the end of a line of text in a plain text file is called the "line terminator". There are three common line terminators, carriage return (CR, ASCII 13, used on Macintosh), linefeed (LF, ASCII 10, used on Unix) and carriage return plus linefeed (CRLF, used on Windows).

When Igor Pro opens a text file (procedure file, plain text notebook or plain text data file), it accepts CR, LF or CRLF as the line terminator.

If you create a new procedure file or plain text notebook, Igor writes CR on Mac OS and CRLF on Windows. As of Igor Pro 5.04, if you open an existing plain text file, edit it and then save it, Igor preserves the original terminator as determined by examining the first line in the file.

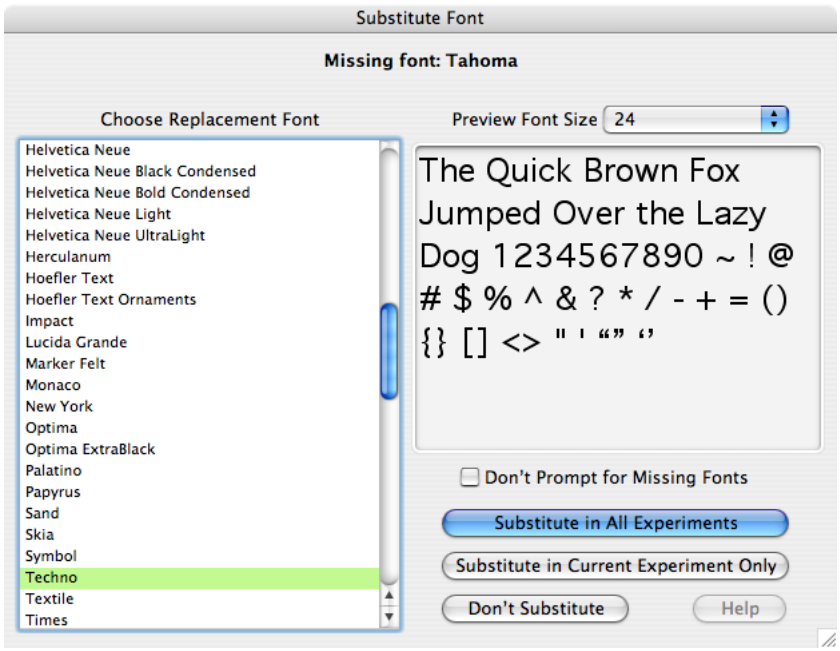
By default, the **FReadLine** operation treats CR, LF, or CRLF as terminators. Use this to write a procedure that can read lines from a text file without caring whether it is a Macintosh, Windows, or Unix file.

Font Substitution

When a font specified in a command or document is not installed Igor will apply font substitution to choose an installed font to use in place of the missing font. Dealing with these missing fonts often occurs when transferring a Windows-originated document to Macintosh or vice versa.

Igor employs two levels of font substitution: user-level editable substitution and built-in uneditable substitution.

The first level is an optional user-level font substitution facility that you will usually encounter for the first time when Igor displays the Substitute Font Dialog while opening an experiment or file. Use the dialog to choose a temporary or permanent replacement for the missing font:



Note: The Substitute Font Dialog appears when neither level of font substitution specifies a replacement for the missing font. You can prevent this dialog from appearing by selecting the Don't Prompt for Missing Fonts checkbox, which is also present in the Edit Font Substitutions Dialog.

The second level is Igor's built-in substitution table which substitutes between fonts normally installed on various Macintosh and Windows operating systems. For example, it substitutes Arial (a standard Windows font) for Geneva (a standard Macintosh font) if Geneva is not installed (which it usually isn't on a Windows computer).

If you prefer to replace Geneva with Verdana, you can use the Edit Font Substitution Dialog (accessed from the Misc menu) to edit the user-level substitutions, which take precedence over any built-in substitutions.

The user-level font substitution table is maintained in the "Igor Font Substitutions.txt" text file in Igor's preferences folder. The file format is:

```
<name of missing font to replace> = <name of font to use instead>
```

one entry per line. For example:

```
Palatino=New Times Roman
```

spaces or tabs are allowed around the equals sign.

When a missing font is replaced, Igor uses the name of the replacement font instead of the name of the font in the command.

The name of the missing font is *replaced* only in the sense that the altered or created object (window, control, etc.) uses and remembers only the name of the replacement font. Recreation macros (and experiment recreation procedures) use the name of the replacement font when the experiment is saved.

The command, however, is unaltered and still contains the name of the missing font.

Example

Suppose an opened experiment's recreation procedures contain commands like these:

```
Display                          // create a blank graph
ModifyGraph gFont="this font doesn't exist"
```

Suppose also that we haven't created an entry in the Edit Font Substitution dialog for a missing font named "this font doesn't exist".

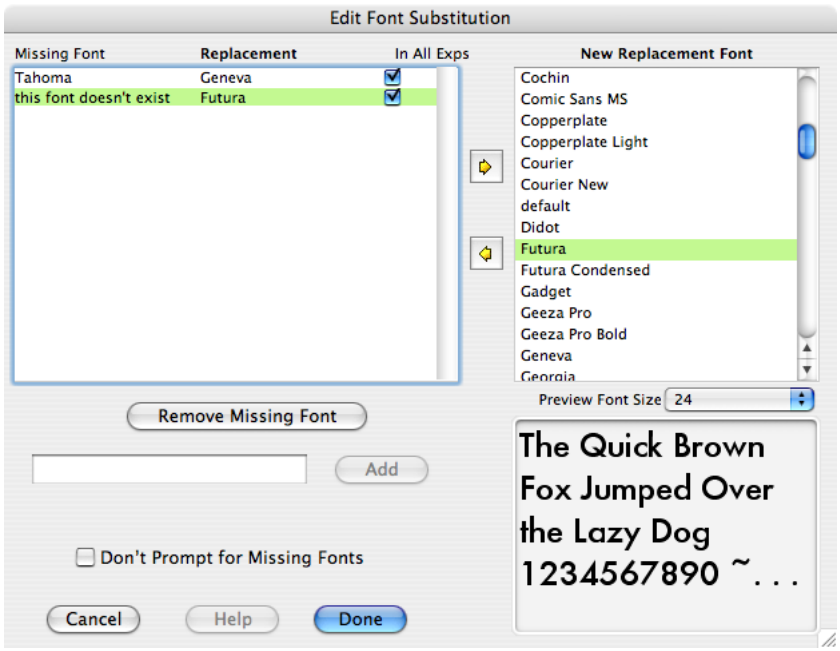
Because the `ModifyGraph gFont` command refers to a nonexistent font, the Substitute Font Dialog appears. Suppose we select a replacement font of Futura.

There are three consequences:

1) The recreation macro of the created graph looks like this:

```
Window Graph0() : Graph
   PauseUpdate; Silent 1      // building window...
   Display /W=(5,44,400,252)
   ModifyGraph gFont="Futura"
EndMacro
```

2) If *another* `ModifyGraph gFont="this font doesn't exist"` command is executed, the Substitute Font dialog does *not* appear, but silently converts the font to Futura.
3) Igor adds the font substitution to the Missing Font list you see in the Edit Font Substitution Dialog:



Cross-Platform Procedure Compatibility

Igor procedures are about 99.5% platform-independent. For the other 0.5%, you need to test which platform you are running on, using the **IgorInfo**(2) function, and act accordingly.

File Paths

As described under **Path Separators** on page III-398, the Macintosh uses colons to separate elements of a file path while Windows uses backslashes. So that you can write a single procedure that works on both platforms, Igor accepts paths with either colons or backslashes on either platform.

The use of backslashes is complicated by the fact that Igor uses the backslash character as an escape character in literal strings. This is also described in detail under **Path Separators** on page III-398. The simplest solution to this problem is to use a colon to separate path elements, even when you are running on Windows.

If you are writing procedures that need to extract sections of file paths or otherwise manipulate file paths, the **ParseFilePath** function on page V-472 may come in handy.

File Types and Extensions

On Mac OS 9, all files had a file type property. This property is a four letter code that is stored with the file by the Macintosh file system. For example, plain text files have the file type TEXT. Igor binary wave files have the file type IGBW. The file type property controls the icon displayed for the file and which programs can open the file.

In Mac OS X, the file type can be represented by the file type property or by the file name extension. Either or both can be used, with the extension preferred.

On Windows, the file type is indicated by the file name extension and files do not have file type properties.

For the most part, in Igor programming you do not need to worry about file types or extensions. However, there are some Igor operations and functions, such as Open and IndexedFile, which take a string parameter containing a file type or list of file types. For example, these commands present a dialog from which a user can choose plain text files or Igor formatted notebook files:

```
Variable fileRef
Open/R/T="TEXTWMT0" fileRef as ""
Close fileRef
```

If you use these operations and functions in procedures, then you need to understand how Igor maps file name extensions to file types.

Igor associates a file type with a file name extension. For example, Igor considers ".txt" files to be of type TEXT and considers ".ifn" files to be of type WMT0. The following table shows how Igor maps from extension to file type:

Windows Extension	Macintosh File Type	What's in the File
.uxp	IGSU	Unpacked experiment file
.uxt	IGSS	Unpacked experiment template (stationery)
.pxp	IGsU	Packed experiment file
.pxt	IGsS	Packed experiment template (stationery)
.ibw	IGBW	Binary wave file
.itx	IGTX	Igor Text file
.xop	IXOP	Igor extension file
.ibv	IGB-	Igor binary variable
.ibt	IGT-	Igor binary misc things
.txt	TEXT	Text file
.ifn	WMT0	Igor formatted notebook file
.ift	WMTS	Igor formatted notebook template (stationery)
.eps	EPSF	Encapsulated PostScript file
.rtf	RTF	Rich Text file
.tif	TIFF	TIFF file
.jpg	JPEG	JPEG file
.tga	TPIC	Targa file
.gif	GIFf	GIF file
.sgi	SGI	Silicon Graphics file
.png	.PNG	Portable Network Graphics file
.psd	8BPS	Photoshop file
.pct	PICT	Macintosh PICT file
.bmp	BMPp	Windows bitmap file
.*	????	Any type file

In addition to the standard Windows extensions listed above, Igor also recognizes files with the ".bwav" and ".awav" extensions. These are recognized as equivalent to ".ibw" and ".itx" for backward compatibility with old versions of Igor.

Igor also maps the following extensions to the associated file type. However, the file types listed in this table are fictitious. They are not file types that are really used on Macintosh but they still work, for example, in the Open operation.

Windows Extension	Fictitious Macintosh File Type	What's in the File
.ihf	IHLP	Igor help file (WMT0 files on Macintosh)
.ipf	IPRC	Procedure file (TEXT files on Macintosh)
.dat	.DAT	Data file
.csv	.CSV	Comma-separated file
.emf	.EMF	Enhanced metafile
.wmf	.WMF	Windows metafile
.bmp	.BMP	Bitmap file
.png	.PNG	PNG file
.htm	HTML	HTML file

Igor maps all extensions not listed above to the file type '????' which signifies "unknown file type". This includes files that have no extension.

The TextFile function will recognize only files of type TEXT. On Windows, a file must have the ".txt" extension to be of type TEXT.

The IndexedFile function requires that you supply a file type or a file extension as a parameter. Thus, the following commands will print the name of the first file in the Igor directory whose type is TEXT (extension is ".txt"):

```
Print IndexedFile(Igor, 0, "TEXT")
Print IndexedFile(Igor, 0, ".txt")
```

This will print the name of the second file of any type:

```
Print IndexedFile(Igor, 1, "????")
```

Points Versus Pixels

Most measurements of length in Igor are in terms of points. A point is roughly 1/72 of an inch.

A pixel is the area taken up by the smallest displayable dot on an output device such as a CRT or a printer. The physical width and height of a pixel depends on the device. CRTs typically display 60 to 120 pixels per inch (commonly called "dots per inch" or DPI). Printers typically display 150 to 2400 DPI.

The physical size of a screen pixel can vary from one CRT to another. The size of a pixel on a given CRT can often be adjusted by the user by twiddling knobs on the back of the CRT or using buttons on the front panel. Because of this, software programs don't know about or worry about the physical size of a pixel but instead deal with an assumed or "logical" size.

On the Macintosh, the logical width and height of a screen pixel is always 1/72 of an inch, which equates to a logical resolution of 72 DPI. The user can change the physical resolution but not the logical resolution. If a monitor's physical resolution is close to 72 DPI, there will be a pretty good match between the logical and physical sizes. On such monitors, if you make a graph 5 inches (360 points) wide, it will appear roughly 5 inches wide.

On Windows, the default logical width and height of a screen pixel is 1/96 of an inch which equates to a logical resolution of 96 DPI. The user can change both the physical resolution and the logical resolution using the Windows Display Properties control panel. It is common to have a significant discrepancy between the logical and physical sizes. In other words, if you make a graph 5 inches (360 points) wide, it may appear 6 or 7 inches wide. If you want the physical size of an object on the screen to match its logical size, you need to find an appropriate combination of physical and logical resolutions.

Window Position Coordinates

With one exception, Igor stores and interprets window position coordinates in units of points. For example the command

```
Display/W=(5, 42, 405, 242)
```

specifies the left, top, right, and bottom coordinates of the window in points relative to a reference point which is, roughly speaking, the top/left corner of the menu bar. Other Igor operations that use window position coordinates in points include Edit, Layout, NewNotebook, PlayMovie and MoveWindow.

The exception is the control panel window. To make it easier to create control panels that look the same on Macintosh and Windows, the NewPanel operation interprets its /W coordinates as pixels and operations that create or modify controls also interpret coordinates as pixels.

Most users do not need to worry about the exact meaning of these coordinates. However, for the benefit of programmers, here is a discussion of how Igor interprets them.

On the Macintosh, the reference point, (0, 0), is the top/left corner of the menu bar on the main screen. On Windows, the reference point is 20 points above the bottom/left corner of the main Igor menu bar. This difference is designed so that a particular set of coordinates will produce approximately the same effect on both platforms, so that experiments and procedures can be transported from one platform to another.

The coordinates specify the location of the content region, in Macintosh terminology, or the client area, in Windows terminology, of the window. They do not specify the location of the window frame or border.

On the Macintosh, a point is always interpreted to be one pixel.

On Windows, the correspondence between a point and a pixel can be controlled by the user, as described under **Points Versus Pixels** on page III-406. Since Igor stores window positions in units of points, if the user changes the number of pixels per point, the size of Igor windows in pixels will change. The exception is that control panels will not change because Igor interprets their coordinates as pixels.

Notebook Issues

On Macintosh, Igor stores the settings (font, size, style, etc.) for a plain text file in the file's resource fork. The data fork contains just the plain text. On Windows, text files have no resource fork. Therefore there is no way for Igor to store settings for a plain text file on Windows. When you open a plain text notebook or an experiment containing a plain text notebook on Windows, Igor uses preferences to set the notebook's text format. Thus, text format changes that you make to a plain text notebook are lost on Windows unless you capture them as your preferred text format.

PNG Pictures in Notebooks

If you want to display notebook pictures on both platforms, they must be in one of these cross-platform formats: PNG, JPEG, TIFF. Although EPS is a cross-platform format, the EPS screen preview on Macintosh is PICT, which is not cross-platform.

If you have pictures in PICT or EMF format and you want them to be viewable on both platforms, you should convert them to PNG. Igor uses PNGs for Igor help files which need to be platform-independent.

There are two ways to create a PNG picture in an Igor notebook. You can load it from a file using Misc→Pictures and then place it in a notebook or you can convert a picture that you have pasted into a notebook using Notebook→Special→Convert to PNG.

The Convert to PNG command in the Notebook→Special menu converts the selected picture or pictures into PNG. It skips selected pictures that are already PNG or that are foreign (not native to the platform on which you are running). You can determine the type of a picture in a notebook by clicking in it and looking at the notebook status line. If you select just one picture and do the conversion, Igor will let you undo it. However, if you select anything other than a single picture, the conversion will not be undoable. You can interrupt a conversion by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*) and holding until Igor stops the conversion.

When you create a PNG file from within Igor, you can create it at screen resolution or at higher resolution. If you want crisp screen display when viewed at 100 percent magnification, use screen resolution when you create the PNG file. If you want better quality when viewed at higher magnifications and when printed, use higher than screen resolution when you create the PNG file. Using higher resolution requires a lot of memory during the conversion and when the picture is displayed but usually does not require excessive disk space when saved because PNGs are compressed. Once you have created a PNG file, you can load it into another program or into Igor using Misc→Pictures.

The next three paragraphs explain how Igor treats screen resolution PNGs differently from high resolution PNGs. You can skip this if you don't care about the technical details.

Normally, Igor stretches pictures if necessary to preserve the logical size of the pictures at different screen resolutions. However, PNG, being a bitmap type of picture, looks best when displayed without stretching. Therefore, Igor treats PNGs in notebooks specially. If the PNG was created at screen resolution, Igor displays the PNG without stretching. This gives a crisp, undistorted display when viewed at 100 percent magnification, but the physical size of the picture is not preserved. This is usually what you want for screen dumps and for graphics intended mostly for viewing on screen at 100% magnification as opposed to printing or viewing on screen at higher magnifications.

For example, suppose you create a 5 inch by 4 inch graph on the Macintosh and export that graph as a screen-resolution PNG. You paste the PNG into a notebook. On the Macintosh, the screen resolution is 72 dpi, so the PNG will be 72 dpi. Thus, the dimensions of the PNG in pixels is 360 by 288 (5*72 by 4*72). If you save the notebook and open it on Windows, Igor notices that the PNG is screen resolution and will therefore displays it using 360 by 288 pixels. This means that Igor does not need to stretch the PNG so it displays crisply. However, because Windows screen resolution is typically 96 dpi, the logical size of the PNG on Windows will be smaller than 5 inches by 4 inches by a factor of 72/96.

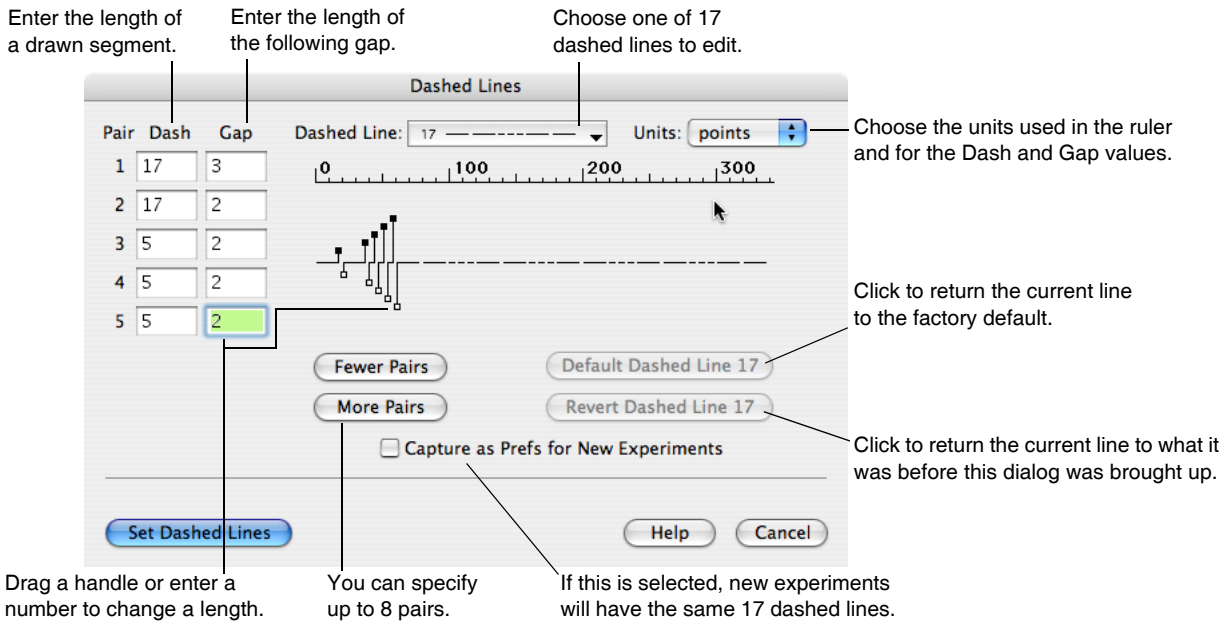
If instead of creating a screen-resolution PNG, you create a high-resolution PNG, Igor will stretch the PNG by a factor of 96/72 on Windows. This makes the logical size of the PNG the same on both platforms but it will be somewhat distorted on Windows because of the stretching.

Chapter
III-16

Miscellany

Dashed Lines

The dashed lines built into Igor can be edited with the Dashed Lines dialog (Misc menu).



You can edit one dashed line pattern at a time. The example shows the last dashed line (number 17) being edited. You can select another line with the Dashed Line pop-up menu. Dashed line 0 (the solid line) cannot be edited. If you need to create a custom dashed line pattern, we recommend that you modify the high numbered dashed lines, leaving the low number ones in their default state. This ensures that the low numbered patterns will be the same for everyone.

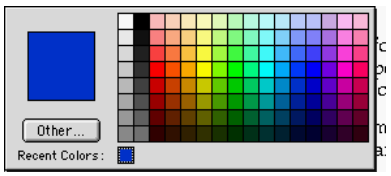
Dashed lines are described by pairs of dash and gap lengths. You can add or remove pairs with the More Pairs and Fewer Pairs buttons. The lengths can be adjusted by entering dash and gap values, or by dragging the dash (filled boxes) and gap (hollow boxes) handles.

You can also change dashed lines with the **SetDashPattern** operation (see page V-552).

Dashed lines are stored with the experiment, so each experiment may have different dashed lines. You can capture the current dashed lines as the preferred dashed lines for new experiments.

The Color Environment

Igor has a main color palette that contains colors that you can use for traces in graphs, text, axes, backgrounds and so on. The main color palette appears as a pop-up menu in a number of dialogs, such as the Modify Trace Appearance dialog. This section discusses this palette.



Igor also has color tables and color index waves you can select among when displaying contour plots and images. These are discussed in Chapter II-14, **Contour Plots**, and Chapter II-15, **Image Plots**.

You can select from colors presented in a color palette.

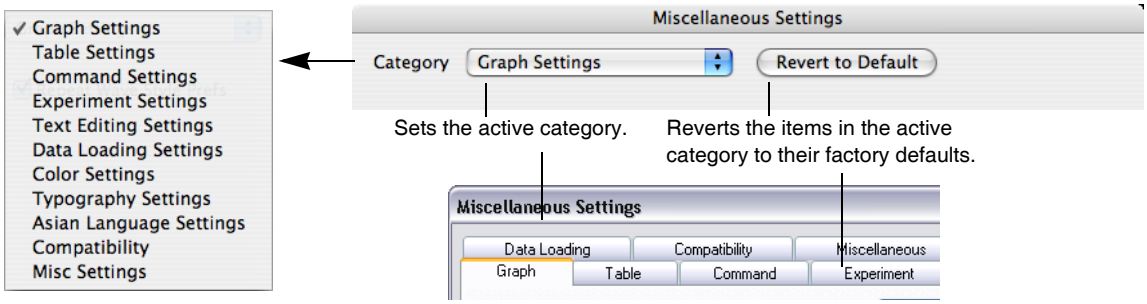
You can use the Other button to select colors that are not in the palette. As you use Igor, colors are added to the palette in the Recent Colors area.

On Macintosh only, the recent colors are remembered by Igor when it quits and restored when it restarts if you have selected the "Save and restore color palette's recent colors" checkbox in the Miscellaneous Settings dialog's Color Settings category.

If you run your monitor in 256 (8 bit) color mode, Igor has to make compromises in an attempt to provide reasonably accurate colors while still allowing other programs to display reasonably accurate colors. It is recommended that you set your monitor to the thousands of colors (16 bit) or millions of colors (32 bit) mode.

Miscellaneous Settings

You can customize some aspects of how Igor works using the Miscellaneous Settings dialog. The miscellaneous settings are grouped into categories.



Changes to miscellaneous settings take effect immediately when you click the Save Settings button. They affect the current experiment as well as new and old (reopened) experiments.

Graph Settings

The Repeat Wave Style Prefs in Graphs checkbox affects the way wave trace style preferences are applied when waves are appended to a graph. The factory default is selected. See **Graph Preferences** on page II-298.

When the Enable "Fling" Mode checkbox is checked, dragging in a graph with Option or Alt pressed and the mouse down will "fling" (scroll) the graph contents in the direction of the drag. To stop the motion, click in the graph while keeping the mouse still.

Table Settings

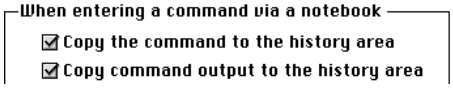
The Repeat Column Style Prefs in Tables checkbox affects the way column style preferences are applied when columns are appended to a table. The factory default is selected. See **Table Preferences** on page II-228.

Command Settings

The Limit Command History Text checkbox determines the number of lines of history text that Igor will retain in a given experiment. The factory default is deselected (no limit). Limiting history can save space on disk but more importantly can reduce clutter in the history area of the command window. It can also reduce the time it takes to open and save an experiment.

If you select the Limit Command History Text checkbox and enter the number of lines of history that you want to keep, Igor will automatically trim the history to that number of lines when you save the experiment. In addition, when Igor adds text to the history, it checks the number of lines. If it exceeds the requested maximum by 500 lines, Igor trims the history at that time, rather than waiting until you save the experiment. This is done so that if, for example, you run an experiment overnight, the history will not grow without bound.

You can enter and execute commands in a notebook as well as from the command window.



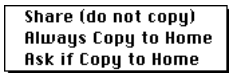
These settings let you determine whether Igor stores commands and output in the history area as well as in the notebook. See **Notebooks as Worksheets** on page III-5 for general information on using a notebook as a worksheet.

Experiment Settings

The Saved Experiment Format pop-up menu controls the way Igor experiments are saved. You can override this choice in the Save Experiment dialog. The choice here merely presets the dialog's Packed checkbox. The factory default is Packed. See **Saving Experiments** on page II-29 for details.

Unlike most spreadsheet and graphing programs, data can exist in Igor without being visible in a table. The "Make a new table for new experiments" checkbox controls whether you will get a new empty table when you choose New Experiment from the File menu. The default state is selected. This is convenient if you generally start working by entering data manually. If you do not enter data manually, you may find it more convenient to turn this checkbox off and create a table only when you need one.

Data Loading Settings



The Loaded Igor Binary Data pop-up menu determines how Igor handles the loading of Igor Binary waves from disk files. This menu addresses a subtlety that caught many early Igor users off guard. Igor Binary data can be shared between experiments. Old versions of Igor defaulted to *sharing* loaded Igor Binary data, but many users thought that a loaded wave was another isolated *copy* of the data.

Use this pop-up menu to choose how Igor handles Igor Binary waves loaded from a disk file. Copy to Home makes an isolated copy of the wave in the experiment's home folder. If the experiment is saved in packed format, the isolated copy is stored in the experiment's packed file, which contains all the things usually stored in a home folder.

If you choose Ask if Copy to Home, you always get a chance to change your mind with a dialog. If you choose Share or Always Copy to Home, you can change your mind only if you use the Load Waves dialog; the Load Igor Binary dialog uses the setting you make here without asking for confirmation. The factory default is Ask if Copy to Home. See **Sharing Versus Copying Igor Binary Files** on page II-165 for details.

Default Data Precision presets the numerical precision checkboxes in the Make Waves and Load Waves dialogs. The factory default is Double. Note that this affects only the dialogs; if you use commands entered manually on the command line the default is single precision. See **Number Type and Precision** on page II-81 for details.

Color Settings (*Macintosh*)

Selecting the "Save and restore color palette's recent colors" checkbox restores the recent colors that were in the color palette when Igor quit. If deselected, Igor starts up with no recent colors. The factory default is deselected (don't restore colors).

The Color Palette menu sets the accuracy with which colors are drawn when you run in 256 color (8 bit) mode. It is recommended that you set your monitor to the thousands of colors (16 bit) or millions of colors (32 bit) mode.

Typography Settings (*Macintosh*)

This section discusses the way Igor draws text in graphs and page layouts.

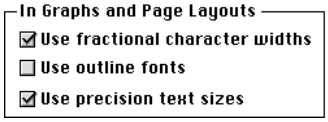
By default, Igor handles text in graphs and page layouts in a method designed to provide good readability of text on the screen and also good fidelity between text on the screen and text on the printed page. If you are satisfied with Igor's default performance in these regards, then you don't need to read the following material.

There is a trade-off to be made between readability of text on the screen and fidelity of text between the screen and the printed page. Unfortunately, there is no way to have maximum readability and maximum fidelity at the same time. You can control this trade-off via three checkboxes in the Typography section of the Miscellaneous Settings dialog.

Achieving text fidelity requires certain actions on the part of Igor, Apple's QuickDraw graphics software and the printer driver. Lack of fidelity stems from the fact that screen resolution is low while printer resolution is high. Because of roundoff and other effects, the width of a string on the screen does not necessarily

match the width of that same string when printed. The reasons for this are too complex to explain here. Apple's technical note TN-TEXT TE 21 gives some idea of the issues involved.

The "Use fractional character widths", "Use outline fonts", and "Use precision text sizes" checkboxes control aspects of how Igor draws text in graphs and page layouts.



The default and recommended state for the "Use fractional character widths" and "Use precision text sizes" checkboxes is on. Turning "Use outline fonts" on makes text in some fonts, such as Geneva and Monaco, difficult to read on screen. Because of this, the default state for this checkbox is off.

When the "Use fractional character widths" checkbox is on, Igor uses Apple's QuickDraw to keep track of the position of characters using higher precision arithmetic. This slightly distorts text on the screen but improves the fidelity with printed text.

When the "Use outline fonts" checkbox is on, Igor uses Apple's QuickDraw to create the outline versions of fonts (TrueType or PostScript) instead of the bitmap versions. This also distorts text on the screen but improves the fidelity with printed text. The "Use outline fonts" checkbox makes a big difference with some fonts, such as Geneva, Monaco and Courier, and makes little difference with other fonts, such as Helvetica, Palatino and Times. Results on your computer may be different because you have different versions of these fonts, different system software or different printer driver software.

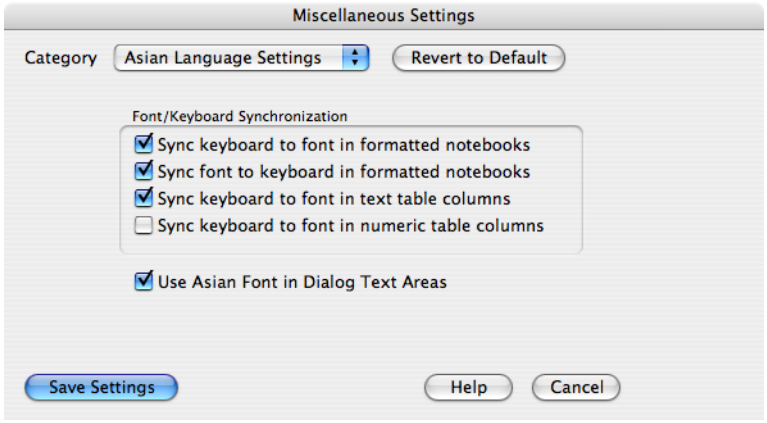
The "Use precision text sizes" checkbox to do a more precise calculation when converting screen text sizes to printer text sizes. The only reason to turn this feature off is to make this version of Igor behave like Igor Pro 2.0.

If all three checkboxes are deselected, you will get the same behavior as in Igor Pro 2.0. This produces good looking text but with less emphasis on text fidelity. Use it only for backward compatibility.

If you change the state of the "Use fractional character widths" or "Use outline fonts", Igor will automatically update all open graphs and page layouts. This is not needed if you change just the Use precision text sizes checkbox because this does not affect what is drawn on the screen.

Asian Language Settings (*Macintosh*)

The Font/Keyboard Synchronization settings control whether or not Igor will automatically match the keyboard input method and the active font. Synchronization applies to text documents and to tables.



The "Sync keyboard to font in text windows" checkbox determines whether Igor will set the keyboard script when you choose a font or click in a section of text in a particular font. If this is selected and you click in Asian text, Igor will activate the Asian keyboard method. If you click in Roman text, Igor will deactivate the Asian keyboard method. Igor chooses the Asian keyboard method if the font is Asian and the text at the insertion point in the document is Asian. Thus, if you mix Asian and Roman characters all in an Asian font, Igor will activate the appropriate keyboard for the text at the insertion point.

The "Sync font to keyboard in text windows checkbox" determines whether Igor will change the font automatically if you manually change the keyboard input method. If this is selected and you change the keyboard input method to Asian, Igor will automatically switch to an Asian font. If you change the keyboard input method to Roman, Igor will automatically switch to a Roman font. You may prefer to enter Roman text in an Asian font. If so then you should deselect this checkbox and manually change the font as needed.

The "Sync keyboard to font in table text columns" checkbox determines whether Igor will set the keyboard script when you click in a text column in a table. If this is on and you click in a column whose font is Asian, Igor will activate the Asian keyboard methods. If you click in a column whose font is Roman, Igor will deactivate the Asian keyboard method.

The "Sync keyboard to font in table numeric columns" checkbox determines whether Igor will set the keyboard script when you click in a numeric column in a table. We recommend that you leave this deselected and use Roman numbers in numeric columns because Igor currently does not understand non-Roman numbers.

The "Use Asian Font for Dialog Text Areas" checkbox controls the font that Igor will use for certain special dialog text entry areas, such as the text entry area in the Add Annotation and Browse Waves dialogs. Because they require advanced capabilities such as scrolling and undo, these areas are not standard Macintosh text boxes but rather are implemented using WaveMetrics' special routines. Normally these areas use the Geneva font. This prevents Asian users from entering Asian characters. When the Use Asian Font for Dialog Text Areas checkbox is selected, Igor will use an Asian font for these areas.

Compatibility Settings

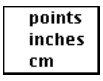
The "Native GUI Appearance for User-defined Controls" checkbox sets the default user-defined control appearance. Deselect it to use the Igor Pro 5 user-defined control appearance.

Deselecting the Floating Tool Palettes and Floating Graph Info Palettes checkboxes sets the tool and info palette locations to be internal to the associated window, as in Igor Pro 5, rather than using the default floating palettes. The settings will affect only new ShowInfo and ShowTools commands; current info and tool palette locations are not affected.

Misc Settings

The "Use short menu bar names" checkbox, when selected, shortened some menu names. If deselected, it uses long menu names. The factory default is deselected (long names). You may want to select this if you are running on a small screen or have many user-defined menus.

The "Maximum pop-up menu items" setting limits the number of menu items in some pop-up menus, such as the pop-up menus of waves, variables, string variables, and the Current Object pop-up menu in the Object Status dialog. Choosing a small value (the minimum is 50) prevents excessive start-up time for dialogs at the expense of listing all the items in the pop-up menus. We recommend that you set this to several hundred. Igor displays the spinning hand watch cursor when building large pop-up menus. You can type Command-period (*Macintosh*) or Ctrl+Break (*Windows*) to stop building the pop-up menu. Some dialogs have multiple pop-up menus that cause the cursor to reappear; you can type Command-period (*Macintosh*) or Ctrl+Break (*Windows*) again.



"Preferred units of length" controls the default units used in the Modify Graph, Print Graph, Export Graph, and Save Graphics dialogs. It does not affect page layouts or notebooks. These have their own preference settings for units (use the Capture Layout Preferences and Capture Notebook Preferences dialogs). This also does not affect the control dialogs (for adding buttons, checkboxes, etc.). These dialogs always use points as the default unit of measure.

"Operations that overwrite or delete folders" determines what to do when a MoveFolder or CopyFolder command is about to overwrite a folder on disk or when a DeleteFolder command is about to delete a folder on disk.

The factory default setting is "Display dialog to ask user for permission". This means that Igor will ask for permission each time one of these operations is about to overwrite or delete a folder on disk. This setting is intended to reduce the chance of accidental or malicious deletion of files.

The other choices are "Always give permission" and "Always deny permission". "Always give permission" grants blanket permission to overwrite or delete folders. Choosing this increases the risk of accidental or malicious deletion of files so you should exercise caution.

(*Macintosh*) "Use Command-H for Find Selection (instead of Command-Control-H)" controls the keyboard shortcut for the "Find Selection" menu item in the Edit menu. The Find Selection keyboard shortcut defaults to Command-Control-H, allowing Command-H to hide Igor on Mac OS X, per Apple's recommendation. The Igor Pro 4 keyboard shortcut of Command-H can be restored by selecting this checkbox. When selected, hiding Igor on Mac OS X requires selecting "Hide Igor" with the mouse.

Keyboard Navigation affects the behavior of keys such as Page Down, Page Up, End and Home.

The Windows Menu Shows popup menu determines how target windows are identified in the submenus of the Windows menu. By default, just the window's title is displayed. You can choose to display the title and/or the name using this setting.

Help Settings (*Windows*)

These are controls governing the display of tool tips, the little windows that pop up automatically when you point at buttons and icons.

Object Names

Every Igor object has a name which you give to the object when you create it or which Igor automatically assigns. You use an object's name to refer to it in dialogs, from commands and from Igor procedures. The named objects are:

Waves	Data folders	Variables (numeric and string)
Windows	Symbolic paths	Pictures
Annotations	Controls	Rulers

In Igor Pro, the rules for naming waves and data folders are not as strict as the rules for naming all other objects, including string and numeric variables, which are required to have standard names. These sections describe the standard and liberal naming rules.

Standard Object Names

Here are the rules for standard object names:

- May be 1 to 31 characters in length.
- Must start with an alphabetic character (A-Z or a-z).
- May include alphabetic or numeric characters or the underscore character.
- Must not conflict with other names (of operations, functions, etc.).

All names in Igor are case insensitive. wave0 and WAVE0 refer to the same wave.

Characters other than letters and numbers, including spaces and periods, are not allowed. We put this restriction on names so that Igor can identify them unambiguously in commands, including waveform arithmetic expressions.

Historical Note: Prior to Igor Pro 3.0, wave names were limited to 18 characters.

Liberal Object Names

The rules for liberal names are the same as for standard names except that almost any character can be used in a liberal name. Liberal name rules are allowed for waves and data folders only.

If you are willing to expend extra effort when you use liberal names in commands and waveform arithmetic expressions, you can use wave and data folder names containing almost any character. If you create liberal names then you will need to enclose the names in single (not curly) quotation marks whenever they are used in commands or waveform arithmetic expressions. This is necessary to identify where the name ends. Liberal names have the same rules as standard names except you may use any character except control characters and the following:

```
"  '  :  ;
```

Here is an example of the creation and use of liberal names:

```
Make 'wave 0';    // 'wave 0' is a liberal name
'wave 0' = p
Display 'wave 0'
```

Note: Providing for liberal names requires extra effort and testing on the part of Igor programmers (see **Programming with Liberal Names** on page IV-147) so you may occasionally experience problems using liberal names with user-defined procedures.

Name Spaces

When you refer to an object by name, in a user function for example, each object must be referenced unambiguously. In general, an object must have a unique name so. Sometimes the object type can be inferred from the context, in which case the name can be the same as objects of other types. Objects whose names can be the same are said to be in different name spaces.

Data folders are in their own name space. Therefore the name of a data folder can be the same as the name of any other object, except for another data folder at the same level of the hierarchy.

Waves and variables (numeric and string) are in the same name space and so Igor will not let you create a wave and a variable in a single data folder with the same name.

An annotation is local to the window containing it. Its name must be unique only among annotations in the same window. The same applies for controls and rulers. Data folders, waves, variables, windows, symbolic paths and pictures are global objects, not associated with a particular window.

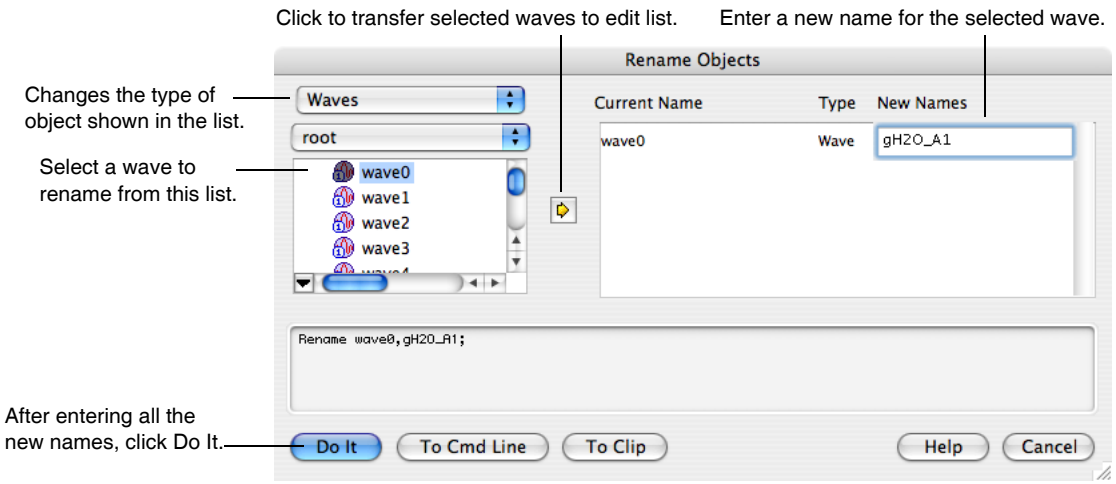
The names of global objects, except for data folders, are required to be distinct from the names of macros, functions (built-in, external or user-defined) and operations (built-in or external).

Here is a summary of the four global name spaces:

Name Space	Requirements
Data folders	Names must be distinct from other data folders at the same level of the hierarchy.
Waves, variables, windows	Names must be distinct from other waves, variables (numeric and string), windows.
Pictures	Names must be distinct from other pictures.
Symbolic paths	Names must be distinct from other symbolic paths.

Renaming Objects

You can use Misc→Rename Objects or Data→Rename to rename waves, variables, strings, symbolic paths, and pictures. Both of these invoke the Rename Objects dialog.



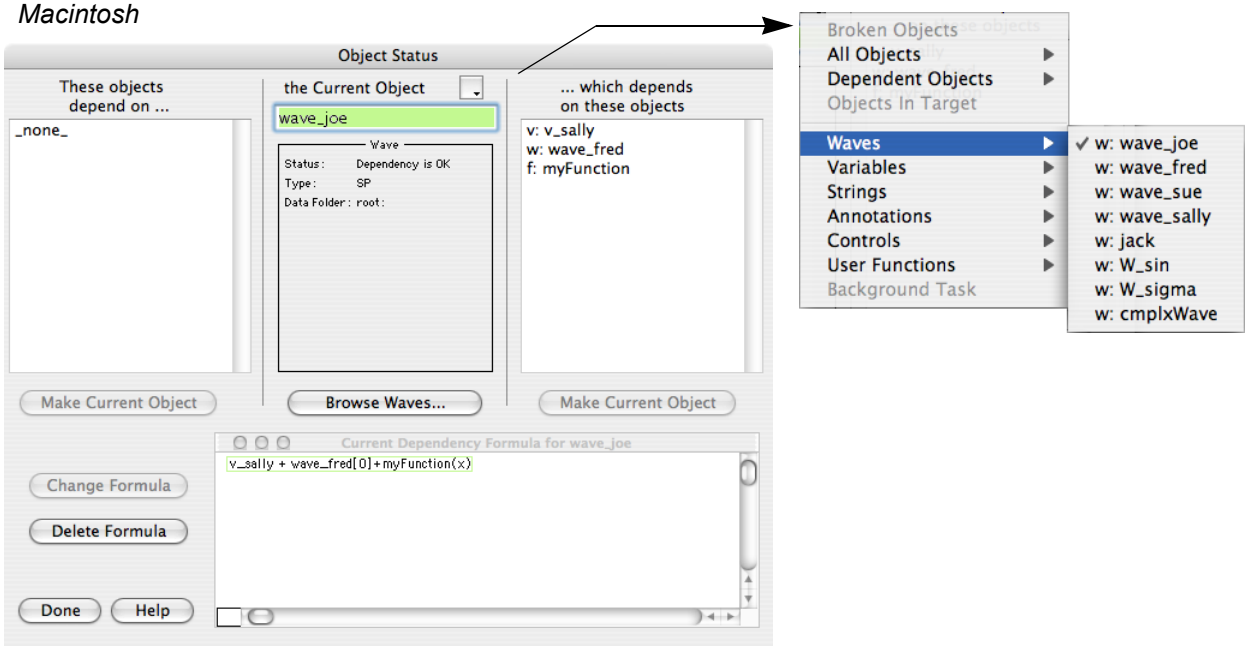
Graphs, tables, page layouts, notebooks, control panels and XOP target windows (e.g., Gizmo 3D plots) are renamed using the **DoWindow** operation (see page V-122) which you can build using the Window Control dialog. See **The Window Control Dialog** on page II-64.

You can use the DataBrowser to rename data folders, waves, and variables. See **Data Browser** on page II-130.

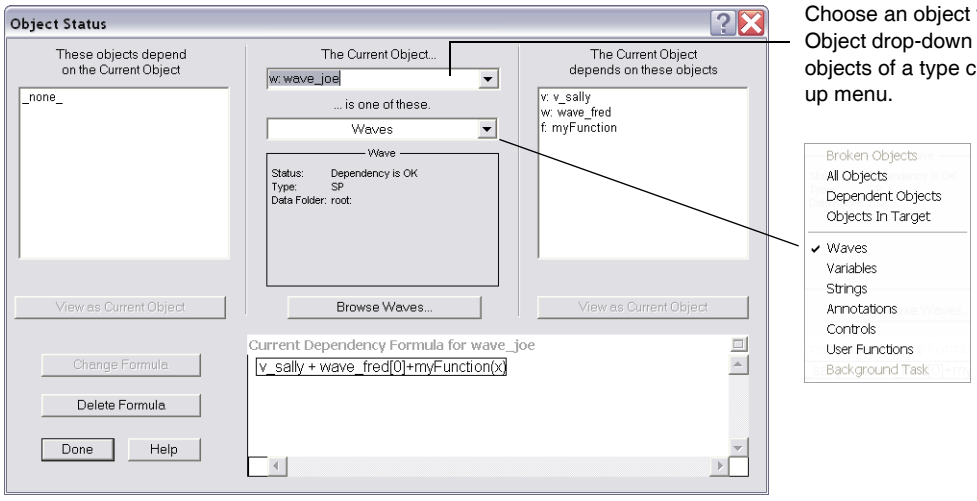
The Object Status Dialog

You can examine the status and interdependencies of named Igor objects with the Object Status dialog. See Chapter IV-9, **Dependencies**, for a discussion of object dependencies. You won't need to use this dialog unless you've got a fairly complex Igor experiment with lots of objects.

Macintosh



Windows



The dialog displays the properties of one object, called the "Current Object". The name of the current object appears at the top center of the dialog. You can choose a new current object from the Current Object pop-up menu.

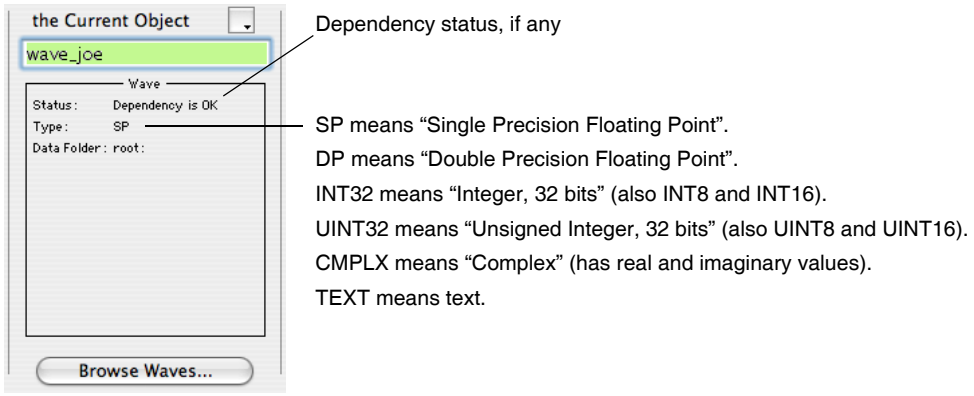
You can also choose a new current object by selecting an object from either of the two **dependency lists** on the left and right of the current object and clicking View as Current Object, or by double-clicking in either list.

Items in the lists and submenus are object names preceded by a key indicating the type of object:

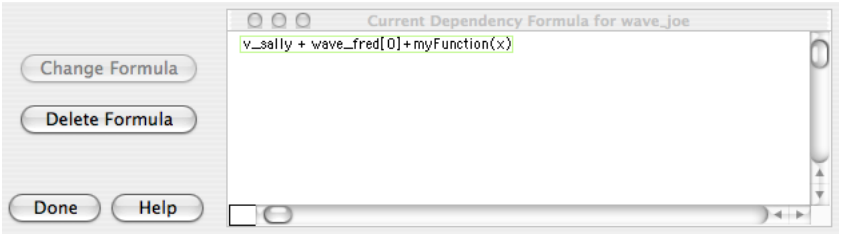
Key	Object Type
a:	annotation
c:	control
f:	function
s:	string

Key	Object Type
t:	task (background task)
v:	variable
w:	wave
=:	dependency formula

The current value, dependency status, and other information about the current object is displayed in the box below the name of the current object. Depending on the type of object, a button may also be present for editing or examining that object.

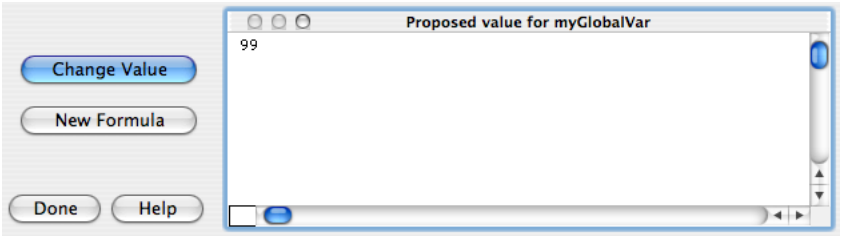


Other current object information is displayed in a windoid near the bottom of the dialog. If the object is a "dependent" object, the dependency formula is shown. This formula can be changed or deleted by clicking the appropriate buttons:

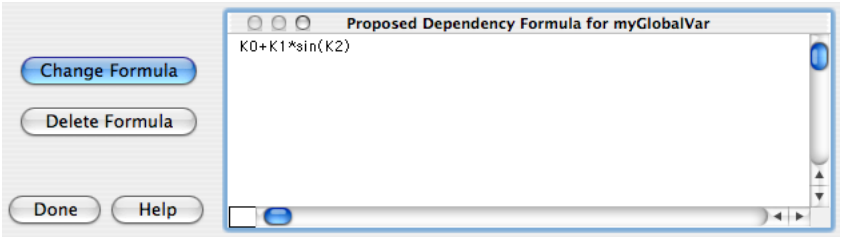


Dependencies and dependency formulas are explained further in Chapter IV-9, **Dependencies**.

You can edit the current value of most nondependent objects in the windoid:



For some nondependent objects, you can also establish a new dependency formula. Click the New Formula button, and an empty formula is created. Enter the desired formula and click Change Formula:



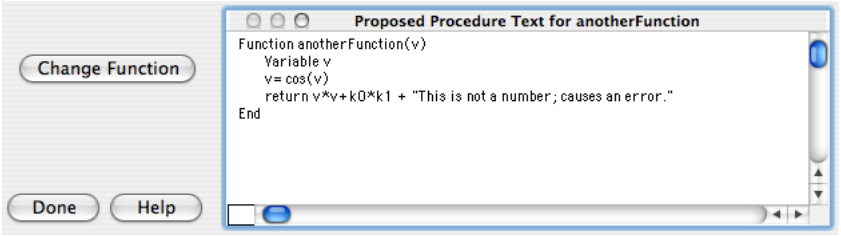
This example established the dependency formula:

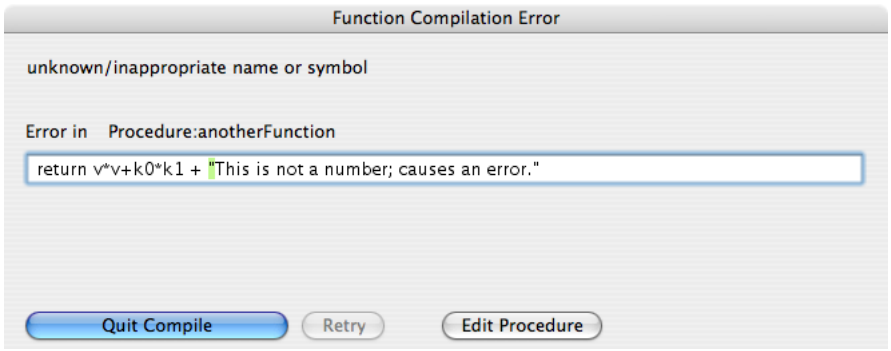
```
myGlobalVar := K0+K1*sin(K2)
```

Whenever `K0`, `K1`, or `K2` changes, `myGlobalVar` will be updated using this formula.

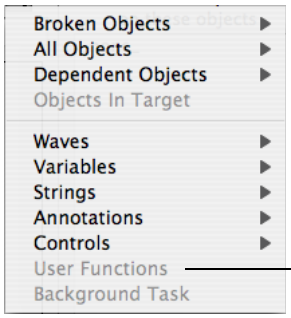
User Functions

You can edit the "current value" of a user-defined function, too. However, if you introduce an error and click Change Function, the function compiler will display an error dialog.





If you then click Quit Compile, the Object Status dialog will come back up, but it will appear as if all the user-defined functions have vanished.



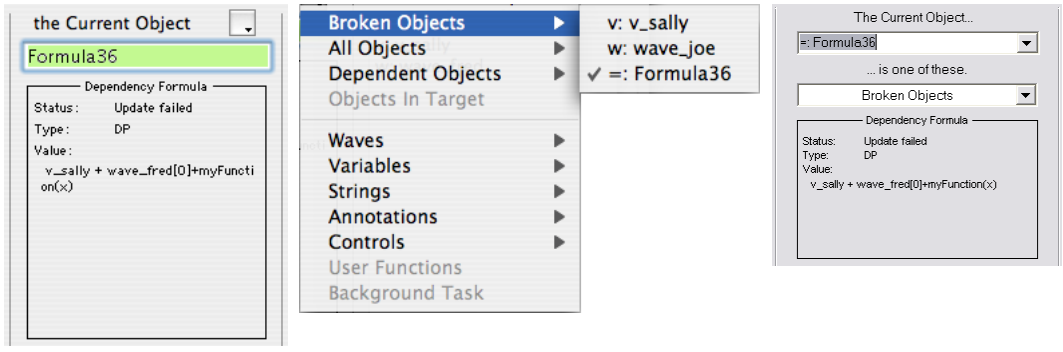
User Functions are not listed when an unresolved compile error exists.

The functions have *not* vanished; Igor just can't display information about functions unless all the procedure windows compile successfully. When you fix the error, the user-defined functions will return.

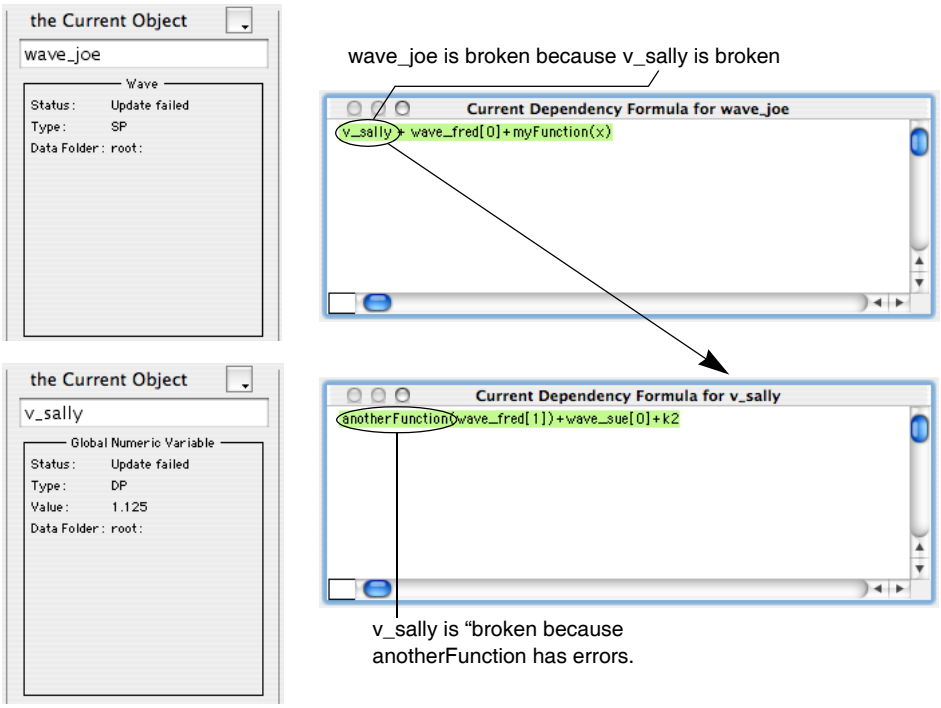
For this reason, it really makes more sense for you to click the Edit Procedure button in the error dialog. This brings up the procedure window in which the function is defined, but it does exit the Object Status dialog first (which would be devoid of function information, anyway). You should fix the error, and then reselect the Object Status dialog. You will find that the function is still the current object, and that all is well.

Broken Objects

If you *don't* fix errors in the user-defined function text, objects that reference the erroneous function will be "**broken**". Those objects are listed in the Broken Objects submenu. The Status field will show why the object is broken.



The usual causes for "Update failed" are either a syntax error in the dependency formula, or some object that the current object depends on (either directly *or indirectly*) has an error, has been renamed, or no longer exists. In this example, it is the unresolved error in the function `anotherFunction` (see **User Functions** on page III-419) which prevents `v_sally` from updating, which in turn causes the update of `wave_joe` through `Formula36` to fail:



Graphics Technology

As of version 6.1, Igor Pro uses more modern graphics code for drawing graphs, tables and page layouts. On Macintosh this involves the radical change of using Apple's Quartz routines rather than the ancient QuickDraw routines. On Windows just slightly more advanced code is used with a small amount of GDI+ instead of GDI.

The new graphics code supports arbitrary rotation for text and imported pictures and, on Macintosh, support for imported PDF pictures which can be placed in graphs, page layouts and formatted notebooks.

The new code does not support the old Macintosh PICT format or the old Windows WMF format. If you need to export PICT or WMF, you can make Igor use the old graphics code by executing this:

```
SetIgorOption UseOldGraphics=1
```

When this command is executed, all graphs and page layout windows are redrawn using the old code.

Windows users may need to revert to the old graphics when exporting EMF to certain programs that do not support the advanced GDI mode. In particular, uses have reported Corel products as not accepting advanced GDI.

You can also turn the old graphics code on if you have a problem with the new code. In this case, please let us know why you needed to do that so we can address the problem.

Pictures

Igor can import pictures from other programs for display in graphs, page layouts and notebooks. It can also export pictures from graphs, page layouts and tables for use in other programs. Exporting is discussed in Chapter III-5, **Exporting Graphics (Macintosh)**, and Chapter III-6, **Exporting Graphics (Windows)**. This section discusses how you can import pictures into Igor, what you can do with them and how Igor stores them.

For information on importing images as data rather than as graphics, see **Loading Other Files** on page II-167.

Importing Pictures

There are three ways to import a picture.

- Pasting from the Clipboard into a graph, layout, or notebook
- Using the Pictures dialog (Misc menu) to import a picture from a file or from the Clipboard
- Using the **LoadPICT** operation (see page V-347) to import a picture from a file or from the Clipboard

Each of these methods, except for pasting into a notebook, creates a *named*, global picture object that you can use in one or more graphs or layouts. Pasting into a notebook creates a picture that is local to the notebook.

This table shows the types of graphics formats from which Igor can import pictures:

Format	How To Import	Notes
PICT	Paste or use Misc→Pictures or LoadPICT	Macintosh only
PDF	Paste or use Misc→Pictures or LoadPICT	Macintosh only
EMF (Enhanced Metafile)	Paste or use Misc→Pictures or LoadPICT	Windows only
BMP (Windows bitmap)	Use Misc→Pictures or LoadPICT	Windows only BMP is sometimes called DIB (Device Independent Bitmap).
PNG (Portable Network Graphics)	Use Misc→Pictures or LoadPICT	Cross-platform bitmap format
JPEG	Use Misc→Pictures or LoadPICT	Cross-platform bitmap format
TIFF (Tagged Image File Format)	Use Misc→Pictures or LoadPICT	Cross-platform bitmap format
EPS (Encapsulated PostScript)	Use Misc→Pictures or LoadPICT	High resolution vector format. Requires PostScript printer. On Windows, a screen preview is displayed on screen.

EPS files usually include a screen preview. The screen preview format is PICT on Macintosh and TIFF on Windows. The screen prevew is not used or needed on Macintosh as the OS converts and displays EPS as PDF on the fly.

The platform-dependent formats (PDF, PICT, EMF, BMP) are drawn as gray boxes when displayed on the nonnative format. The cross-platform formats can be displayed on either platform, except that Macintosh EPS pictures display as boxes on Windows, because the screen preview format (PICT) is platform-dependent. Also, EPS pictures which have no screen preview display as boxes on Windows.

EPS pictures provide the highest quality but on Windows should only be used if you are certain you will be printing on a PostScript printer or exporting to a PostScript-savvy application such as Adobe Illustrator. On Macintosh, they can be used wherever a PDF could be used.

When non-EPS pictures are used in a graphic that is exported as EPS, the picture is rendered as a bitmap which has lower quality than an EPS picture.

See also **Picture Compatibility** on page III-395 for a discussion of Macintosh graphics on Windows and vice-versa.

The Picture Collection Stores Named Pictures

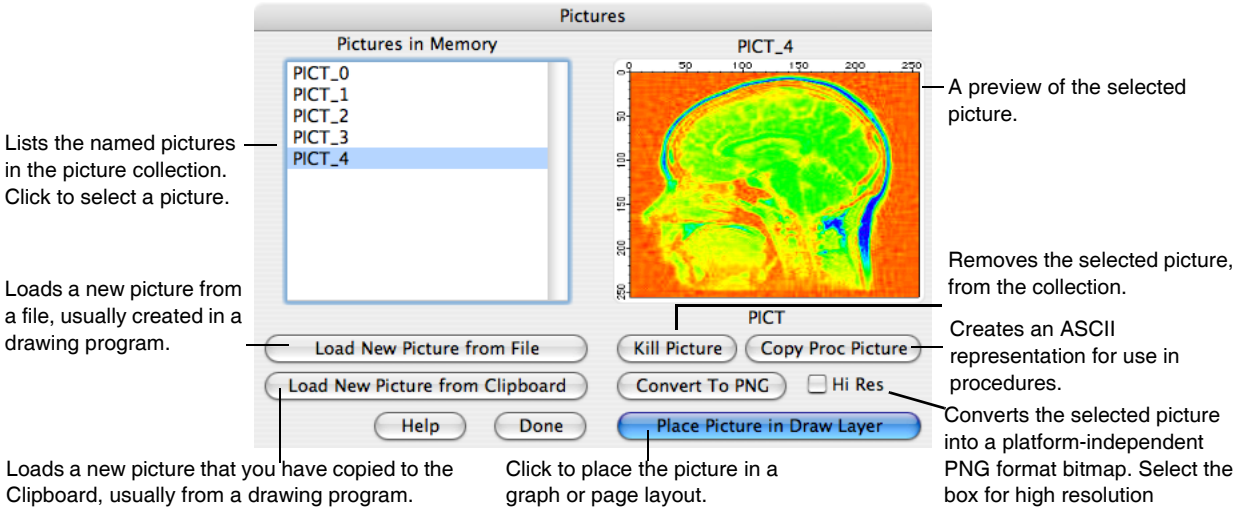
When you create a named picture using one of the techniques listed above, Igor stores it in the current experiment's **picture collection**. When you save the experiment, the picture collection is stored in the experiment file. You can inspect the collection using the Pictures dialog via the Misc menu.

Igor gives names to pictures so they can be referenced from an Igor procedure. For example, if you paste a picture into a layout, Igor assigns it a name of the form "PICT_0" and stores it in the picture collection. If you then close the layout and ask Igor to create a recreation macro, the macro will reference the picture by name.

You can rename a named picture using the Pictures dialog in the Misc menu, the Rename Objects dialog in the Misc menu, the Rename dialog in the Data menu, or the **RenamePICT** operation (see page V-520). You can kill a named picture using the Pictures dialog or the **KillPICTs** operation (see page V-322).

Pictures Dialog

The Pictures dialog permits you to view the picture collection, to add pictures, to remove pictures and to place a picture into a graph or page layout. It also can place a copy of a picture into a formatted notebook. To invoke it, choose Pictures from the Misc menu.



The Kill This Picture button will be dimmed if the selected picture is used in a currently open graph or layout.

Note: Igor determines if a picture is in use by checking to see if it is used in an *open* graph or layout window.

If you kill a graph or layout that contains a picture and create a recreation macro, the recreation macro will *refer* to the picture by name. However, Igor does not check for this. It will consider the picture to be unused and will allow you to kill it. If you later run the recreation macro, an error will occur when the macro attempts to append the picture to the graph or layout. Therefore, don't kill a picture unless you are sure that it is not needed.

NotebookPictures

When you paste a picture into a formatted notebook, you create a notebook picture. These work just like pictures in a word processor document. You can copy and paste them. These pictures will not appear in the Pictures or Rename Objects dialogs.

Igor Extensions

Igor includes a feature that allows a C or C++ programmer to extend its capabilities. An Igor extension is called an "XOP" (short for "external operation"). The term XOP comes from that fact that, originally, adding a command line operation was all that an extension could do. Now extensions can add operations, functions, menus, dialogs and windows.

WaveMetrics XOPs

The "Igor Pro Folder/Igor Extensions" and "Igor Pro Folder/More Extensions" folders contain XOPs that we developed at WaveMetrics. These add capabilities such as file-loading and instrument control to Igor and

also serve as examples of what XOPs can do. These XOPs range from very simple to rather elaborate. Most XOPs come with help files that describe their operation.

The WaveMetrics XOPs are described in the XOP Index help file, accessible through the Windows→Help Windows submenu.

Third Party Extensions

A number of Igor users have written XOPs to customize Igor for their particular fields. Some of these are freeware, some are shareware and some are commercial programs. WaveMetrics publicizes third party XOPs through our Web page. User-developed XOPs are available from http://www.igorexchange.com. Also, we make some third party XOPs available via FTP. See **FTP Sites** on page II-15 for details on FTP.

Activating Extensions

The Igor installer creates a folder called Igor Extensions inside the Igor Pro Folder. The Igor installer puts some XOP files in this folder. XOPs in this folder are loaded when Igor starts up.

The installer puts less-frequently used XOPs in "Igor Pro Folder/More Extensions". These are not available unless you activate them.

If you place in "Igor Pro Folder/Igor Extensions" an alias (Macintosh) or shortcut (Windows) for an XOP file or a folder containing XOP files, Igor loads those files also. However, this is not the recommended way to activate an XOP.

Your operating system may not allow you to make changes to the contents of your Igor Pro Folder, for example, if you do not have permission to write to that folder. For that reason Igor Pro 6.1 or later also loads extensions from another folder - "Igor Pro User Files/Igor Extensions" (see **Igor Pro User Files** on page II-46 for details). You can locate this folder by selecting Help→Show Igor Pro User Files.

If you press the shift key while clicking the Help menu, you can choose Help→Show Igor Pro Folder andUser Files. Igor then opens the Igor Pro Folder and the Igor Pro User Files folder on the desktop, making it easy to drag aliases/shortcuts into "Igor Pro User Files/Igor Extensions". This is the recommended way to activate additional XOPs for a given user.

If you want to activate an extension for all users on a given machine, you can put the alias or shortcut in "Igor Pro Folder/Igor Extensions" folder. Windows 7 does not permit you to manually create a shortcut in the Igor Pro Folder but you can create the shortcut on the desktop and drag it into the Igor Pro Folder.

Changes that you make to either Igor Extensions folder take effect the next time Igor is launched.

See **Creating Igor Extensions** on page IV-181 if you are a programmer interested in writing your own XOPs.

XOPs on Intel Macintosh

To run an XOP on Intel Macintosh it must be ported to the Intel architecture. WaveMetrics has ported most of its XOPs and distributes them as universal executables, which means that they run on both PowerPC and Intel Macintosh. The Igor Pro 6 application is also universal.

Because third-party libraries are not yet available, the following WaveMetrics XOPs have not yet been ported to run with the Intel version of Igor Pro: NIGPIB, NIGPIB2.

In addition, the NetCDF Loader XOP, written by Igor user Katsuhisa Kitano and ported to Mac OS X by WaveMetrics, has not yet been ported to Intel.

If you use a third-party XOP that has not yet been ported to Intel, you can not run it with the Intel version of Igor.

The Igor Pro installer places non-Intel WaveMetrics Macintosh XOPs in the PPC Extensions folder.

If you run the Intel Macintosh version of Igor Pro with a PowerPC-only XOP installed, it will not display an error message and will ignore the PowerPC-only XOP. Similarly, if you run the PowerPC version of Igor with an Intel-only XOP installed, it will not display an error message and will ignore the Intel-only XOP.

Running PowerPC XOPs on Intel Macintosh

If you need to run an XOP that has not been ported to Intel Macintosh, you must run the PowerPC version of Igor Pro. You can do this on an Intel Macintosh by checking the Open Using Rosetta checkbox in the Finder Info window for the Igor Pro application located in the Igor Pro folder.

With the Open Using Rosetta checkbox checked, the PowerPC code in the Igor Pro 6 application package will run any PowerPC XOPs that you invoke.

Memory Management

On Mac OS X, each 32-bit application (such as Igor Pro) is allocated 4 GB of virtual address space. On Windows, 32-bit applications are allocated 2 GB of virtual address space by default but there is a technique (explained below) for increasing this to 3 GB or 4 GB.

Theoretically, applications can allocate memory up the limit of the virtual address space. The operating system allocates physical memory as necessary. If the total amount of allocated virtual memory exceeds the total amount of physical memory, the operating system will temporarily write some data to disk and load other data into physical memory — a process called "swapping". This can make the computer very slow.

When a program is launched, the operating system maps the program's code into its virtual address space, thereby diminishing the space available for data. During the program's initialization, it allocates many blocks of data, thousands in Igor's case, for things like windows, controls and internally-used structures. This further reduces the amount of virtual memory space available for data.

As you work, creating windows, procedures, variables, waves and other objects, Igor allocates more blocks of virtual memory. When you kill a window, wave or other object, Igor deallocates blocks of virtual memory. This leaves free blocks in the virtual memory space.

Blocks of virtual memory space that are free because of deallocation are generally discontiguous. The largest contiguous block is smaller than the total amount of free virtual memory. The free virtual memory space is split into fragments that can not be joined because they are separated by allocated blocks. As you allocate and deallocate memory, the virtual memory space becomes more and more fragmented.

Another cause of fragmentation is the loading of dynamic link libraries.

When you create an object, for example, a wave, Igor needs a contiguous block of virtual memory. If the space needed for the wave is larger than the largest contiguous block of virtual memory, the allocation will fail and Igor will return an out-of-memory error.

Fragmentation sets the limit for the largest wave you can create. This is an issue if you are creating very large waves that require, typically, 250 MB or more. If you are creating a large number of smaller waves, for example, 100 waves of 10 MB each, fragmentation is generally not an issue.

Increasing Virtual Memory Space in Windows VISTA and Windows 7

If you are running Windows VISTA x64 (64-bit) or Windows 7 x64 (64-bit), the operating system allows 32-bit applications like Igor to use 4 GB of virtual address space. You can not increase this.

On Windows 7 x64 with 4 GB of physical memory the largest wave we were able to create was 2000 MB.

If you are running Windows VISTA (32-bit) or Windows 7 (32-bit), by default applications get a 2 GB virtual address space. You can increase this to 3 GB using the BCDEdit program to change your boot settings. To do this, click the Windows Start button, choose Programs→Accessories and then right-click Command Prompt. Choose Run As Administrator. In the Command Prompt window, enter this command:

```
BCDEdit /Set IncreaseUserVa 3072
```

Now reboot. Igor should now have a 3 GB virtual address space.

Increasing Virtual Memory Space in Windows XP

If you are running Windows XP Professional x64 (64-bit), the operating system allows 32-bit applications like Igor to use 4 GB of virtual address space. You can not increase this.

If you are running Windows XP Professional (32-bit), by default applications get a 2 GB virtual address space. You can increase this to 3 GB by changing a setting on your computer, specifically by adding the /3GB flag to your C:\boot.ini file.

Note: Be careful! If you mess up your boot.ini file, your computer will not boot. This procedure should be attempted only by advanced Windows computer users.

The boot.ini is invisible by default. To see it you must use Explorer's Tools→Folder Options to enable viewing hidden files and disable hiding protected system files. Alternatively you can use the System control panel, Advanced Tab, Startup and Recovery section to edit it.

Back up the boot.ini file before making any changes to it.

Open boot.ini in Notepad and add the /3GB flag to the appropriate partition. For example, after adding the flag, the relevant line in boot.ini may look like this:

```
multi(0)disk(0)rdisk(0)partition(1)\WINDOWS="Microsoft Windows XP Professional"
/fastdetect /3GB
```

When you next boot, the operating system will allow Igor to use 3 GB of virtual address space instead of 2 GB.

The /3GB flag has no effect on programs that do not have the special flag set.

On Windows XP SP3 with 2 GB of physical memory and a 3 GB virtual address space, the largest wave we were able to create was about 600 MB. We were able to increase this to 880 MB by applying a Microsoft hotfix that reduces memory fragmentation. The hotfix is available from http://support.microsoft.com/kb/894472.

Macintosh System Requirements

Igor Pro 6.1 requires Mac OS X 10.4.0 or later. It runs native on PowerPC and Intel processors.

Igor Pro 6 does not run on Mac OS 9.

Windows System Requirements

Igor Pro requires Windows XP, Windows Vista or Windows 7.

Igor Pro 6.1 does not run on Windows 95, Windows 98, Windows ME, Windows NT or Windows 2000.

Crashes

A crash results from a software bug and prevents a program from continuing to run. Crashes are highly annoying at best and, at worst, can cause you to lose valuable work.

WaveMetrics uses careful programming practices and extensive testing to make Igor as reliable and bug-free as we can. However in Igor as in any complex piece of software it is impossible to exterminate all bugs. Also, crashes can sometimes occur in Igor because of bugs in other software, such as printer drivers, video drivers or system extensions.

We are committed to keeping Igor a solid and reliable program. If you experience a crash, we would like to know about it.

When reporting a crash to WaveMetrics, please include the following information:

- The exact version of Igor Pro (e.g., 6.10) that you are running.
- The exact operating system (e.g., Mac OS X 10.4.7, Windows XP) that you are running.
- A description of what actions preceded the crash and whether it is reproducible.
- A recipe for reproducing the crash, if possible.
- A crash log (described below), if possible.

We have three methods for determining the cause of a crash.

The first method is to reproduce it on our computers. For this we need a recipe from you, if possible.

If we can not reproduce the crash, our second method is to examine the source code looking for possible bugs. For this, we need a detailed description from you of what you were doing when the crash occurred so that we know what part of the source code to examine.

Our last resort is to examine the crash log for a clue as to where the crash occurred. This sometimes provides useful information, sometimes not.

Crash Logs on Mac OS X

When a crash occurs on Mac OS X, most of the time the system is able to generate a crash log. You can usually find it at:

```
/Users/<user>/Library/Logs/DiagnosticReports/Igor Pro_<date>_<machinename>.crash
```

or

```
/Users/<user>/Library/Logs/CrashReporter/Igor Pro.crash.log
```

where <user> is your user name.

For irreproducible crashes, send this log as an attachment to support@wavemetrics.com. Include the other information listed above.

Crashes On Windows

When a crash occurs on Windows XP, but not Windows VISTA or Windows 7, most of the time the system is able to generate a crash log. You can usually find it at:

C:\Documents and Settings\All Users\Application Data\Microsoft\Dr Watson\drwtsn32.log

The Application Data folder is normally hidden. To make it visible, go into the All Users folder and choose Tools→Folder Options. Click the View tab, then the Show Hidden Files and Folders radio button, and the OK button.

You can also search for the drwtsn32.log file. In this case, make sure to include hidden files and folders in the search.

For irreproducible crashes, send this log as an attachment to support@wavemetrics.com. Include the other information listed above.

If you install a software development system such as Microsoft Visual C++, the development system will set itself up as the default debugger and Dr. Watson will not run when a crash occurs. In this case you will have no drwtsn32.log file.

On Windows VISTA and Windows 7, the operating system does not produce a user-accessible crash log. Your best bet is to try to determine a recipe to reproduce the crash or a pattern that leads to the crash and send a report to support@wavemetrics.com.

Chapter III-17

Preferences

Overview

Preferences affect the creation of *new* graphs, panels, tables, layouts, notebooks, and procedure windows, and the *appending* of traces to graphs and columns to tables. In addition, preferences affect the command window, default font, and font size menus in new experiments.

You can turn preferences off or on using the Misc menu. Normally you will run with preferences on.

Preferences are automatically off while a procedure is running so that the effects of the procedure will be the same for all users. See the **Preferences** operation (see page V-497) for further information.

When preferences are off, factory default values are used for settings such as graph size, position, line style, size and color. When preferences are on, Igor applies your preferred values for these settings.

Preferences differ from *settings* (the Miscellaneous Settings dialog) in that settings generally take effect immediately, while preferences are used when something is created. See **Miscellaneous Settings** on page III-411.

Igor Preferences Directory

Preferences are stored in a per-user directory. The location of this directory depends on your operating system and configuration, but here are some typical locations:

Mac OS X	hd:Users:<*user*>:Library:Preferences:WaveMetrics:Igor Pro 6 PowerPC: *or* hd:Users:<*user*>:Library:Preferences:WaveMetrics:Igor Pro 6 Intel:
Windows	C:Documents and Settings:<*user*>:Application Data:WaveMetrics:Igor Pro 6:

where <*user*> is the name of the current user. The preferences directory may be hidden by some operating systems.

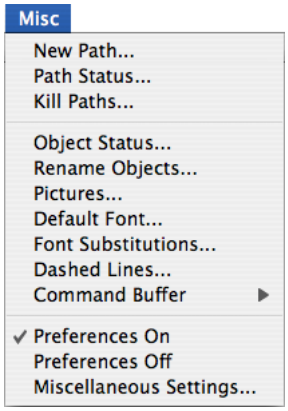
You can find the operating-system-defined location for preferences by executing this command:

```
Print SpecialDirPath("Preferences", 0, 0, 0)
```

Deleting the preferences directory effectively reverts all preferences to factory defaults. You should use the Capture Prefs dialogs, described in **Captured Preferences** operation on page III-431, to revert preferences more selectively.

Other information is stored in this directory, such as the screen position of dialogs, a few dialog settings, colors recently selected in the color palette, window stacking and tiling information, page setups, font substitution settings, and dashed line settings.

How to Use Preferences



Preferences are always on when Igor starts up. You can turn preferences off by choosing Preferences Off in the Misc menu.

You can also turn preferences on and off with the **Preferences** operation (see page V-497).

Preferences are set by Capture Preferences dialogs, the Tile or Stack Windows dialog, and some dialogs such as the Dashed Lines dialog.

There is just one set of preferences for all experiments. This means that preferences set while running one experiment will be in effect when you run the next experiment. This is handy because you only need to specify your preferences once.

In general, *preferences are applied only when something new is created* such as a new graph, a new trace in a graph, a new notebook, a new column in a table, and then only if preferences are on.

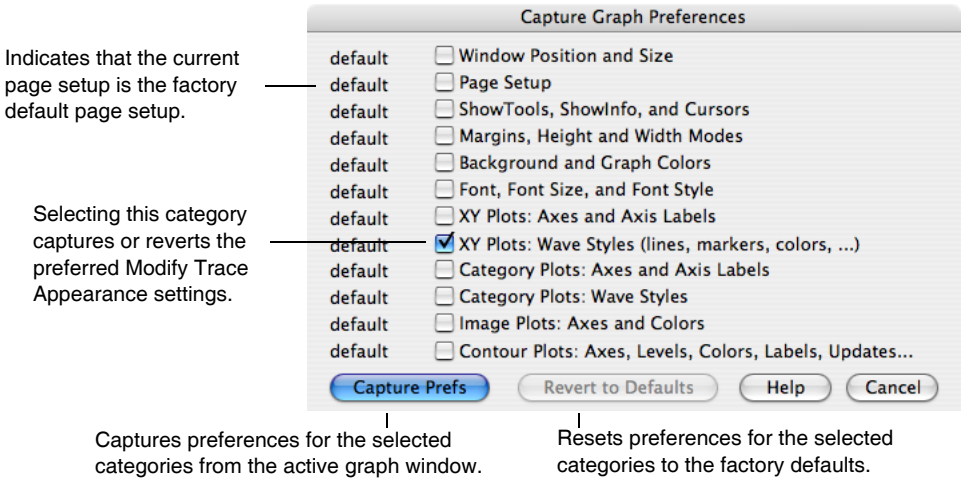
Preferences are normally in effect only for *manual* ("point-and-click") operation, not for user-programmed operations in Igor procedures. See **When Preferences Are Applied** on page III-432.

Captured Preferences

You set most Preference values by capturing the current settings of the active window with the Capture Prefs item in the menu for that window. (The dialog to capture the Command Window preferences is found in the Command/History Settings submenu of the Misc menu.) The dialogs are described in more detail in the chapter that discusses each type of window. For instance, see **Graph Preferences** on page II-298.

As an example, suppose you want your graphs to always draw appended waves with a one-half point blue line, rather than the factory default one point red line. You can set your preference by creating a graph with one wave displayed using a one-half point blue line, and then "capturing" that preferred setting with the Capture Graph Preferences dialog.

Choose Capture Graph Prefs from the Graph menu:



Save the wave style preference by selecting the XY Plots: Wave Styles category and clicking Capture Prefs. From now on, when you append a wave to an existing graph, or create a new graph containing a trace, the trace will be displayed with your preferred one-half point blue line.

Most capture preferences dialogs are like this Capture Graph Preferences dialog; they have various categories with checkboxes. Selecting a category means that you wish to change the preferences for that category. You may either capture the current settings for that category by clicking the Capture Prefs button, or you may revert the preferences for that category by clicking the Revert to Defaults button. If a category has been reverted to its default setting, "default" is indicated to the left of the checkbox. If "default" is not present, this means that the category settings have previously been captured.

Current Captured Preference Values

The Capture Preferences dialogs do not show the current *values* for the settings in the categories. The only way to discover what captured values are is to create a new window of that type and examine the settings with dialogs or readback functions. Any value not set to the factory default value must have been set by the preferences. (To check the factory default values, create a new window with Preferences off.)

For example, to determine what the values captured by the Capture Graph Preferences dialog are:

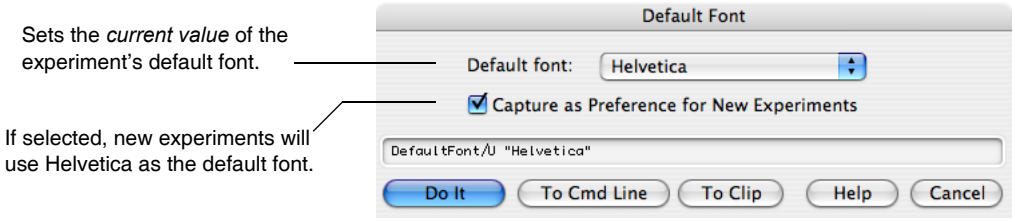
- Turn Preferences on (in the Misc menu).
- Create a new graph.
- Append some waves.

- Create a graph recreation macro using the Window Control dialog, and examine the values assigned by the resulting macro (this works well because graph recreation macros generate commands only to change values from their factory defaults).
- Or, use the Modify Waves Appearance dialog to observe the settings for the displayed waves. These are the captured user-preferred values.

Capturing Other Settings

In addition to the preferences captured by the various Capture Prefs dialogs, Igor remembers a number of other settings. Many of these can be set using the Miscellaneous Settings dialog, described in **Miscellaneous Settings** on page III-411.

Some settings are captured in dialogs whose main purpose is to change the *current* value of some settings. Such a dialog is the Default Font dialog:



It can capture the preferred Default Font with or without changing the current value. The Dashed Lines and Tile or Stack Windows dialogs also work this way.

The positions of dialogs on your desktop are always remembered in the preferences file. On Macintosh only, Recent Colors are remembered if the appropriate checkbox in the Misc Settings dialog is selected.

On both Macintosh and Windows, the font sizes you add to the Text Size menu are automatically remembered, as well as fonts substitution settings and various other dialog settings.

When Preferences Are Applied

In general, *preferences are applied only when something new is created* such as a new graph, a new wave in a graph, a new notebook, a new column in a table, and then only if preferences are on. In some cases, preferences affect what happens when you create a new experiment.

Igor has, in effect, two independent settings for whether preferences are on or off. The Preferences On and Preferences Off items in the Misc menu control the setting for *manual* ("point-and-click") operations, and is initially (and normally) set to "on". Another setting is used when a procedure (macro or function) is executing, and is normally set to "off".

We usually don't want preferences to affect the behavior of procedures. If we allowed preferences to take effect during procedure execution, a change in preferences could change the effect of a procedure, making it unpredictable. For more information, see **Procedures and Preferences** on page IV-178.

Chapter
IV-1

Working with Commands

Overview

Igor's user interface is unique in providing both a graphical user interface and a parallel path using command line operations. Although you can get by ignoring the command line, if you do so you will miss out on much of Igor's power and flexibility.

Even if you are a casual user you should learn at least the basics of assignment statements. Most users should read this entire chapter — especially those who expect to program Igor.

You can execute commands by typing them into the command line and pressing Return or Enter. You can also incorporate commands into procedures (functions and macros) that you write in the Procedure window. You can execute a procedure by typing its name in the command line or by choosing its item from the Macros menu. You can also use a notebook for entering commands. See **Notebooks as Worksheets** on page III-5.

You can type commands from scratch but often you will let Igor dialogs formulate and execute commands. You can view a record of what you have done in the history area of the command window and you can easily reenter, edit and reexecute commands stored there. See **Command Window Shortcuts** on page II-25 for details.

Multiple Commands

You can place multiple commands on one line if you separate them with semicolons. For example:

```
wave1= x; wave1= wave2/(wave1+1); Display wave1
```

You don't need a semicolon after the last command but it doesn't hurt.

Comments

Comments start with //, which end the executable part of a command line. The comment continues to the end of the line. There is no way to insert a comment in the middle of a command line.

Maximum Length of a Command

The total length of the command line can not exceed 400 characters.

There is no line continuation character in Igor. However, it is nearly always possible to break a single command up into multiple lines using intermediate variables. For example:

```
Variable a = sin(x-x0)/b + cos(y-y0)/c
```

can be rewritten as:

```
Variable t1 = sin(x-x0)/b
Variable t2 = cos(y-y0)/c
Variable a = t1 + t2
```

Parameters

Every place in a command where Igor expects a numeric parameter you can use a numeric expression. Similarly for a string parameter you can use a string expression. In an operation flag (e.g., /N=<number>), you must parenthesize expressions. See **Expressions as Parameters** on page IV-11 for details.

Liberal Object Names

In general, object names in Igor are limited to a restricted set of characters. Only letters, digits and the underscore character are allowed. Such names are called "standard names". This restriction is necessary to identify where the name ends when you use it in a command.

For waves and data folders only, you can also use "liberal" names. Liberal names can include almost any character, including spaces and dots (see **Liberal Object Names** on page III-415 for details). However, to define where a liberal name ends, you must quote them using single quotes.

In the following example, the wave names are liberal because they include spaces and therefore they must be quoted:

```
'wave 1' = 'wave 2'     // Right
wave 1 = wave 2         // Wrong - liberal names must be quoted
```

Note: Providing for liberal names requires extra effort and testing by Igor programmers (see **Programming with Liberal Names** on page IV-147) so you may occasionally experience problems using liberal names with user-defined procedures.

Data Folders

Data folders provide a way to keep separate sets of data from interfering with each other. You can examine and create data folders using the Data Browser (Data menu). There is always a root data folder and this is the only data folder that many users will ever need. Advanced users may want to create additional data folders to organize their data.

You can refer to waves and variables either in the current data folder, in a specific data folder or in a data folder whose location is relative to the current data folder:

```
// wave1 is in the current data folder
wave1 = <expression>

// wave1 is in a specific data folder
root:'Background Curves':wave1 = <expression>

// wave1 is in a data folder inside the current data folder
:'Background Curves':wave1 = <expression>
```

In the first example, we use an object name by itself (wave1) and Igor looks for the object in the current data folder.

In the second example, we use a full data folder path (root:'Background Curves':) plus an object name. Igor looks for the object in the specified data folder.

In the third example, we use a relative data folder path (:'Background Curves':) plus an object name. Igor looks in the current data folder for a subdata folder named Background Curves and looks for the object within that data folder.

Important: The right-hand side of an assignment statement (described under **Assignment Statements** on page IV-4) is evaluated in the context of the data folder containing the destination object. For example:

```
root:'Background Curves':wave1 = wave2 + var1
```

For this to work, wave2 and var1 must be in the Background Curves data folder.

Examples in the rest of this chapter use object names alone and thus reference data in the current data folder. For more on data folders, see Chapter II-8, **Data Folders**.

Types of Commands

There are three fundamentally different types of commands that you can execute from the command line:

- assignment statements
- operation commands
- user-defined procedure commands

Here are examples of each:

```
wave1= sin(2*pi*freq*x)       // assignment statement

Display wave1,wave2 vs xwave  // operation command

MyFunction(1.2,"hello")       // user-defined procedure command
```

As Igor executes commands you have entered, it must determine which of the three basic types of commands you have typed. If a command starts with a wave or variable name then Igor assumes it is an assignment statement. If a command starts with the name of a built-in or external operation then the command is treated as an operation. If a command begins with the name of a user-defined macro, user-defined function or external function then the command is treated accordingly. Each of these types is discussed in greater detail under **Assignment Statements** on page IV-4, **Operation Commands** on page IV-9, and **User-Defined Procedure Commands** on page IV-9.

Note that built-in functions can only appear in the right-hand side of an assignment statement, or as a parameter to an operation or function. Thus, the command:

```
sin(x)
```

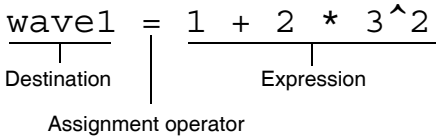
is not allowed and you will see the error, "Expected wave name, variable name, or operation." On the other hand, these commands are allowed:

```
print sin(1.567)              // sin is parameter of print command
wave1 = 5*sin(x)              // sin in right side of assigment
```

If, perhaps due to a misspelling, Igor can not determine what you want to do, it will put up an error dialog and the error will be highlighted in the command line.

Assignment Statements

Assignment statement commands start with a wave or variable name. The command assigns a value to all or part of the named object. An assignment statement consists of three parts: a destination, an assignment operator, and an expression. For example:



This assigns 19 to every point in wave1.

The spaces in the above example are not required. You could write:

```
wave1=1+2*3^2
```

See **Waveform Arithmetic and Assignments** on page II-93 for details on wave assignment statements.

In the following examples, str1 is a string variable, created by the String operation, var1 is a numeric variable, created by the Variable operation, and wave1 is a wave, created by the Make operation.

```
str1 = "Today is " + date()                 // string assignment

str1 += ", and the time is " + time()       // string concatenation

var1 = strlen(str1)                         // variable assignment

var1 = pnt2x(wave1,numpnts(wave1)/2)        // variable assignment

wave1 = 1.2*exp(-0.2*(x-var1)^2)            // wave assignment

wave1[3] = 5                                // wave assignment

wave1[0,;3]= wave2[p/3] *exp(-0.2*x)        // wave assignment
```

These all operate on objects in the current data folder. To operate on an object in another data folder, you need to use a data folder path:

```
root:'run 1':wave1[3] = 5          // wave assignment
```

See Chapter II-8, **Data Folders**, for further details.

If you use liberal wave names (see **Object Names** on page III-415), you must use quotes:

```
'wave 1' = 'wave 2'         // Right
wave 1 = wave 2             // Wrong
```

Assignment Operators

The assignment operator determines the way in which the expression is combined with the destination. Igor supports the following assignment operators:

Operator	Assignment Action
=	Destination contents are set to the value of the expression.
+=	Expression is added to the destination.
-=	Expression is subtracted from the destination.
*=	Destination is multiplied by the expression.
/=	Destination is divided by the expression.
:=	Destination is dynamically updated to the value of the expression whenever the value of any part of the expression changes. The := operator is said to establish a "dependency" of the destination on the expression.

For example:

```
wave1 = 10
```

sets each Y value of the wave1 equal to 10, whereas:

```
wave1 += 10
```

adds 10 to each Y value of wave1. This is equivalent to:

```
wave1 = wave1 + 10
```

The assignment operators =, := and += work with string assignment statements but -=, *= and /= do not. For example:

```
String str1; str1 = "Today is "; str1 += date(); Print str1
```

prints something like "Today is Fri, Mar 31, 2000".

For more information on the := operator, see Chapter IV-9, **Dependencies**.

Operators

Here is a complete list of the operators that Igor supports in the expression part of an assignment statement in order of precedence:

Operator	Effect
^	Exponentiation
- ! ~	Negation, logical complement, bitwise complement
* /	Multiplication, division
+ -	Addition or string concatenation, subtraction
== != > < >= <=	Comparison operators
& | %^	Bitwise AND, bitwise OR, bitwise XOR
&& || ? :	Logical AND, logical OR, conditional operator
$	Substitute following string expression as name

Unary negation changes the sign of its operand. Logical complementation changes nonzero operands to zero and zero operands to 1. Bitwise complementation converts its operand to an unsigned integer by truncation and then changes it to its binary complement.

Exponentiation raises its left-hand operand to a power specified by its right-hand operand. That is, 3^2 is written as 3^2. In an expression a^b, if the result is assigned to a real variable or wave, then a must not be negative if b is not an integer. If the result is used in a complex expression, any combination of negative a, fractional b or complex a or b is allowed.

If the exponent is an integer Igor evaluates the expression using only multiplication. There is no need to write a^2 as a*a to get efficient evaluation — Igor does the equivalent automatically. If, on the other hand, the exponent is not an integer then the evaluation is performed using logarithms, hence the restriction on negative a in a real expression.

Logical OR (||) and logical AND (&&) determine the truth or falseness of pairs of expressions. The AND operation returns true only when both expressions are true; OR will return true if *either* is true. As in C, true is *any* nonzero value, and false is zero. The operations are undefined for NaNs. These operators are not available in complex expressions.

The logical operators are evaluated from left to right, and an operand will not be evaluated if it is not necessary. For the example:

```
if(MyFunc1() && MyFunc2())
```

when MyFunc1() returns false (zero), then MyFunc2() will not be evaluated because the entire expression is already false. This can produce unexpected consequences when the right-hand expression has side effects, such as creating waves or setting global values.

Bitwise AND (&), OR (|), and XOR (%^) convert their operands to an unsigned integer by truncation and then return their binary AND, OR or exclusive OR.

The conditional operator (? :) is a shorthand form of an if-else-endif expression. In the statement:

```
<expression> ? <TRUE> : <FALSE>
```

the first operand, <expression>, is the test condition; if it is nonzero then Igor evaluates the <TRUE> operand; otherwise <FALSE> is evaluated. Only one operand is evaluated according to the test condition. This is the same as if you had written:

```
if( <expression> )
   <TRUE>
else
   <FALSE>
endif
```

The ":" character in the conditional operator must always be separated from the two adjacent operands with a space. If you omit either space, you will get an error ("No such data folder") because the expression can also be interpreted as part of a data folder path. To be safe, always separate the operands from the operator symbols with a space.

The operands must be numeric; for strings, use the **SelectString** function. When using complex expressions with the conditional operator, only the real portion is used when the operator evaluates the expression.

The conditional operator can easily cause confusion, so you should exercise caution when using it. For example, it is unclear from simple inspection what Igor may return for

```
1 ? 2 : 3 ? 4 : 5
```

(4 in this case), whereas

```
1 ? 2 : (3 ? 4 : 5)
```

will return 2. Always use parentheses to remove any ambiguity.

The comparison operators return 1 if the result of the comparison is true or 0 if it is false. For example, the == operator returns 1 if its operands are equal or 0 if they are not equal. The != operator returns the opposite. Because comparison operators return the values 1 or 0 they can be used in interesting ways. The assignment:

```
wave1 = sin(x)*(x<=50) + cos(x)*(x>50)
```

sets wave1 so that it is a sine wave below x=50 and a cosine wave above x=50. See also **Example: Comparison Operators and Wave Synthesis** on page II-98.

Note that the double equal sign, ==, is used to mean equality while the single equal sign, =, is used to indicate assignment.

Because of roundoff error, using == to test two numbers for equality may give incorrect results. It is safer to use <= and >= to see if a number falls in a narrow range. For example, imagine that you want to compare a variable to see if it is equal to one-third. The expression:

```
(v1 == 1/3)
```

is subject to failure because of roundoff. It is safer to use something like

```
((v1 > .33332) && (v1 < .33334))
```

If the numbers are integers then the use of == is safe because integers smaller than 2^{53} (approximately 10^{16}) are represented precisely in double-precision floating point numbers.

The previous discussion on operators has assumed numeric operands. The + operator is the only one that works with both numeric *and* string operands. For example, if str1 is a string variable then the assignment statement

```
str1 = "Today is " + "a nice day"
```

assigns the value "Today is a nice day" to str1. The other string operator, $ is discussed in **String Substitution Using $** on page IV-15.

Unless specified otherwise by parentheses, unary negation or complementation are carried out first followed by exponentiation then by multiplication or division followed by addition or subtraction then by comparison operators. The wave assignment:

```
wave1 = ((1 + 2) * 3) ^ 2
```

assigns the value 81 to every point in wave1, but

```
wave1 = 1 + 2 * 3 ^ 2
```

assigns the value 19.

Note: `-a^b` is an exception to this rule and is evaluated as `-(a^b)`.

The precedence of string substitution, substrings, and wave indexing is somewhat complex. When in doubt, use parenthesis to enforce the precedence you want.

Obsolete Operators

As of Igor Pro 4.0, the old bitwise complement (%~), bitwise AND (%&), and bitwise OR (%|) operators have been replaced by new versions that omit the % character from the operator. These old bitwise operators can still be used interchangeably with the new versions.

Operands

In addition to literal numbers like 3.141 or 27, operators can operate on variables and function values. In the assignment statement:

```
var1 = log(3.7) + var2
```

the operator + operates on the function value returned by log and on the variable var2. Functions and function values are discussed later in this chapter.

Numeric Type

In Igor, each numeric destination object (wave or variable) has its own numeric type. The numeric type consists of the numeric precision (e.g., double precision floating point) and the number type (real or complex). Waves can be single or double precision floating point or various sizes of integer but variables are always double precision floating point.

The numeric precision of the destination does not affect the calculations. With the exception of a few operations that are done in place such as the FFT, all calculations are done in double precision.

Although waves can have integer numeric types, wave expressions are always evaluated in double precision floating point. The floating point values are converted to integers by rounding as the final step before storing the value in the wave. If the value to be stored exceeds the range of values that the given integer type can represent, the results are undefined.

The number type of the destination determines the initial number type (real or complex) of the assignment expression. This is important because Igor can not deal with "surprise" or "runtime" changes in number type. An example would be taking the square root of a negative number requiring that all following arithmetic be done using complex numbers.

Here are some examples:

```
Variable a, b, c, var1
Variable/C cvar1
Make wave1

var1= a*b
cvar1= c*cmplx(a+1,b-1)
wave1= var1 + real(cvar1)
```

The first expression is evaluated using the real number type. The second expression contains a mixture of two types. The multiplication of c with the result of the cmplx function is evaluated as complex while the arguments to the cmplx function are evaluated as real. The third example is evaluated as real except for the argument to the real function which is evaluated as complex.

Constant Type

You can define named numeric and string constants in Igor procedure files and use them in the body of user-defined functions.

Constants are defined in procedure files using following syntax:

```
Constant <name1> = <literal number> [, <name2> = <literal number>]

StrConstant <name1> = <literal string> [, <name2> = <literal string>]
```

You can use the static prefix to limit the scope to the given source file. For debugging, you can use the Override keyword as with functions.

These declarations can be used in the following ways:

```
constant kFoo=1,kBar=2
strconstant ksFoo="hello",ksBar="there"

static constant kFoo=1,kBar=2
static strconstant ksFoo="hello",ksBar="there"

override constant kFoo=1,kBar=2
override strconstant ksFoo="hello",ksBar="there"
```

Programmers may find that using the "k" and "ks" prefixes will make their code easier to read.

Names for numeric and string constants can conflict with all other names. Duplicate constants of a given type are not allowed (except static in different files and when used with Override). The only true conflict is

with variable names and with certain built-in functions that do not take parameters such as pi. Variable names override constants, but constants override functions such as pi.

Dependency Assignment Statements

You can set up global variables and waves so that they automatically recalculate their contents when other global objects change. See Chapter IV-9, **Dependencies**, for details.

Operation Commands

An operation is a built-in or external routine that performs an action but, unlike a function, does not directly return a value. Here are some examples:

```
Make/N=512 wave1
Display wave1
Smooth 5, wave1
```

Operation commands perform the majority of the work in Igor and are automatically generated and executed as you work with Igor using dialogs.

You can use these dialogs to experiment with operations of interest to you. As you click in a dialog, Igor composes a command. This provides a handy way for you to check the syntax of the operation or to generate a command for use in a user-defined procedure. See Chapter V-1, **Igor Reference**, for a complete list of all built-in operations. Another way to learn their syntax is to use the Igor Help Browser's Command Help tab. See **Command Help Tab** on page II-6.

The syntax of operation commands is highly variable but in general consists of the operation name, followed by a list of options (e.g., `/N=512`), followed by a parameter list. The operation name specifies the main action of the operation and determines the syntax of the rest of the command. The list of options specifies variations on the default behavior of the operation. If the default behavior of the operation is satisfactory then no options are required. The parameter list identifies the objects on which the operation is to operate. Some commands take no parameters. For example, in the command:

```
Make/D/N=512 wave1, wave2, wave3
```

the operation name is "`Make`". The list of options is "`/D/N=512`". The parameter list is "`wave1, wave2, wave3`". An option such as "`/D`" or "`/N=512`" is sometimes termed a "flag".

You can use numeric expressions in the parameter list of an operation where Igor expects a numeric parameter, but in an operation option you need to parenthesize the expression. For example:

```
Variable val = 1.0
Make/N=(val) wave0, wave1
Make/N=(numpnts(wave0)) wave2
```

The most common types of parameters are literal numbers or numeric expressions, literal strings or string expressions, names, and waves. In the example above, wave1 is a name parameter when passed to the Make operation. It is a wave parameter when passed to the Display and Smooth operations. A name parameter can refer to a wave that may or may not already exist whereas a wave parameter must refer to an existing wave.

See **Parameter Lists** on page IV-11 for general information that applies to all commands.

User-Defined Procedure Commands

For details on creating your own procedures, refer to chapters starting with IV-2.

User-defined procedure commands start with a macro, user function, or external function name followed by a list of parameters in parentheses. Here are a few examples:

```
MyFunction1(5.6, wave0, "igneous")
MyMacro1(1.2, 1/sqrt(ln(2)), "wave0")
MyMacro1(1.2 ,  ,  )
MyMacro1( )
```

Macro and Function Parameters

As illustrated by the last two examples, you can invoke macros (but not functions) with one or more of the input parameters missing. When you do this, Igor puts up a dialog to allow you to enter the missing parameters. When you run a macro by choosing it from the Macros menu, Igor simply executes the macro with all of the parameters missing as in the last example. After you enter values in the dialog, the macro is executed with those parameters and the now-complete macro command is placed in the history. You can then fetch the command from the history, modify a parameter and then reexecute the command without having to go through the dialog.

You can add similar capabilities to user-defined functions using the **Prompt** (see page V-508) and **DoPrompt** (see page V-121) keywords. You can also use the **PauseForUser** (see page V-476) operation in a function to provide a more sophisticated way to get user input. WaveMetrics encourages programmers to use user-defined functions instead of macros.

There is an additional difference between functions and macros that you should be aware of. Functions can accept numeric, string and wave reference parameters. Macros can accept numeric and string parameters but can not accept literal wave names. For this reason, macros are written to accept waves in the form of strings containing the wave names. It's the difference between wave0 and "wave0" in the first two examples above.

When you are using a package of procedures written by someone else you may need to determine what parameters a particular macro or function requires. If this is not documented you can easily inspect the source code by opening the procedure window and choosing the desired procedure from the pop-up menu at the bottom of the window.

Function Commands

A function is a routine that directly returns a numeric or string value. There are three classes of functions available to Igor users:

- Built-in
- External (XFUNCs)
- User-defined

Built-in numeric functions enjoy one advantage over external or user-defined functions: a few come in real and complex number types and Igor automatically picks the appropriate version depending on the current number type in an expression. External and user-defined functions must have different names when different types are needed. Generally, only real user and external functions need be provided.

For example, in the wave assignment:

```
wave1 = enoise(1)
```

if wave1 is real then the function enoise returns a real value. If wave1 is complex then enoise returns a complex value.

You can use a function as a parameter to another function, to an operation, to a macro or in an arithmetic or string expression so long as the data type returned by the function makes sense in the context in which you use it.

User-defined and external functions can also be used as commands by themselves. Use this to write a user function that has some purpose other than calculating a numeric value, such as displaying a graph or making new waves. Built-in functions cannot be used this way. For instance:

```
MyDisplayFunction(wave0)
```

External and user-defined functions can be used just like built-in functions. In addition, numeric functions can be used in curve fitting. See Chapter IV-3, **User-Defined Functions** and **Fitting to a User-Defined Function** on page III-171.

Most functions consist of a function name followed by a left parenthesis followed by a parameter list and followed by a right parenthesis. In the wave assignment shown at the beginning of this section, the function

name is enoise. The parameter is 1. The parameter is enclosed by parentheses. In this example, the result from the function is assigned to a wave. It can also be assigned to a variable or printed:

```
K0 = enoise(1)
Print enoise(1)
```

User and external functions (but not built-in functions) can be executed on the command line or in other functions or macros without having to assign or print the result. This is useful when the point of the function is not its explicit result but rather its side effects.

Nearly all functions require parentheses even if the parameter list is empty. For example the function date() has no parameters but requires parentheses anyway. There are a few exceptions. For example the function Pi returns π and is used with no parentheses or parameters.

Igor's built-in functions are described in detail in Chapter V-1, **Igor Reference**.

Parameter Lists

Parameter lists are used for operations, functions, and macros and consist of one or more numbers, strings, keywords or names of Igor objects. The parameters in a parameter list must be separated with commas.

Expressions as Parameters

In an operation, function, or macro parameter list which has a numeric parameter you can always use a numeric expression instead of a literal number. A numeric expression is a legal combination of literal numbers, numeric variables, numeric functions, and numeric operators. For example, consider the command

```
SetScale x, 0, 6.283185, "v", wave1
```

which sets the X scaling for wave1. You could also write this as

```
SetScale x, 0, 2*PI, "v", wave1
```

Parentheses Required for /N=(<expression>)

Many operations accept flags of the form "/A=n" where A is some letter and n is some number. You can use a numeric expression for n but you must parenthesize the expression.

For example, both:

```
Make/N=512 wave1
Make/N=(2^9) wave1
```

are legal but this isn't:

```
Make/N=2^9 wave1
```

A variable name is a form of numeric expression. Thus, assuming v1 is the name of a variable:

```
Make/N=(v1)
```

is legal, but

```
Make/N=v1
```

is not. This parenthesization is required only when you use a numeric expression in an operation flag.

String Expressions

A string expression can be used where Igor expects a string parameter. A string expression is a legal combination of literal strings, string variables, string functions and the string operator + which concatenates strings.

Setting Bit Parameters

A number of commands require that you specify a bit value to set certain parameters. In these instances you set a certain bit *number* by using a specific bit *value* in the command. The bit value is 2^n, where *n* is the bit number. So, to set bit 0 use a bit value of 1, to set bit 1 use a bit value of 2, etc.

For the example of the TraceNameList function the last parameter is a bit setting. To select normal traces you must set bit 0:

```
TraceNameList("",";",1)
```

and to select contour traces set bit 1:

```
TraceNameList("",";",2)
```

Most importantly, you can set multiple bits at one time by adding the bit values together. Thus, for TraceNameList you can select both normal (bit 0) and contour (bit 1) traces by using:

```
TraceNameList("",";",3)
```

See also **Using Bitwise Operators** on page IV-33.

Strings

Igor has a rich repertoire of string handling capabilities. See **Strings** on page V-10 for a complete list of Igor string functions. Many of the techniques described in this section will be of interest only to programmers.

Many Igor operations require *string* parameters. For example, to label a graph axis, you can use the Label operation:

```
Label left, "Volts"
```

Other Igor operations, such as Make, require *names* as parameters:

```
Make wave1
```

Using the string substitution technique, described in **String Substitution Using $** on page IV-15, you can generate a name parameter by making a string containing the name and using the $ operator:

```
String stringContainingName = "wave1"
Make $stringContainingName
```

String Expressions

Wherever Igor requires a string parameter, you can use a string expression. A string expression can be:

- A literal string (`"Today is"`)
- The output of a string function (`date()`)
- An element of a text wave (`textWave0[3]`)
- Some combination of string expressions (`"Today is" + date()`)

In addition, you can derive a string expression by indexing into another string expression. For example,

```
Print ("Today is" + date())[0,4]
```

prints “Today”.

A string variable can store the result of a string expression. For example:

```
String str1 = "Today is" + date()
```

A string variable can also be part of a string expression, as in:

```
Print "Hello. " + str1
```

Strings in Text Waves

A text wave contains an array of text strings. Each element of the wave can be treated using all of the available string manipulation techniques. In addition, text waves are commonly used to create category axes in bar charts. See **Text Waves** on page II-103 for further information.

There is a potential ambiguity with string indexing when the string is stored in a text wave. See **String Indexing** on page IV-13.

String Properties

Strings in Igor can be of unlimited length. There are no restrictions on the characters that can be stored in a string except for the null character (ASCII code 0). Storing a null in a string causes problems because the C functions that Igor uses internally to handle strings take null as an end-of-string flag.

Some Igor functions can take an empty string (`""`, no space between the quotation marks) as a parameter.

Escape Characters in Strings

Igor treats the backslash character in a special way when reading literal (quoted) strings in a command line. The backslash is used to define something called an "escape sequence". This just means that the backslash plus the next character or next few characters are treated like a different character — one you could not otherwise include in a quoted string. The escape sequences are:

`\t`	Tab character
`\r`	Return character
`\n`	Linefeed character
`\'`	The ' character
`\"`	The " character
`\\`	The \ character
`\ddd`	An arbitrary ASCII code (ddd is a 3 digit octal number)

For example, if you have a string variable called "fileName", you could print it in the history area using:

```
fileName = "Test"
Printf "The file name is \"%s\"\r", fileName
```

which prints

```
The file name is "Test"
```

In the Printf command line, `\"` embeds a double-quote character in the format string. If you omitted the backslash, the " would end the format string. The `\r` specifies that you want a carriage return in the format string.

String Indexing

Indexing can extract a part of a string. This is done using a string expression followed by one or two numbers in brackets. The numbers are character positions. Zero is the character position of the first character; n-1 is the character position of the last character of an n character expression. For example, assume we create a string variable called s1 and assign a value to it as follows:

```
String s1="hello there"
```

h	e	l	l	o		t	h	e	r	e
0	1	2	3	4	5	6	7	8	9	10

Then,

`Print s1[0,4]` prints `hello`

```
Print s1[0,0]                   prints   h
Print s1[0]                     prints   h
Print s1[1]+s1[2]+s1[3]         prints   ell
Print (s1+" jack")[6,15]        prints   there jack
```

A string indexed with one number, such as s1[p], is a string with one character in it if p is in range (i.e. 0 ≤ p ≤ n-1). s1[p] is a string with no characters in it if p is not in range. For example:

```
Print s1[0]                     prints   h
Print s1[-1]                    prints   (nothing)
Print s1[10]                    prints   e
Print s1[11]                    prints   (nothing)
```

A string indexed with two numbers, such as s1[p1,p2], contains all of the characters from s1[p1] to s1[p2]. For example:

```
Print s1[0,10]                  prints   hello there
Print s1[-1,11]                 prints   hello there
Print s1[-2,-1]                 prints   (nothing)
Print s1[11,12]                 prints   (nothing)
Print s1[10,0]                  prints   (nothing)
```

Because the syntax for string indexing is identical to the syntax for wave indexing, you have to be careful when using text waves. For example:

```
Make/T textWave0 = {"Red", "Green", "Blue"}

Print textWave0[1]              prints   Green
Print textWave0[1][1]           prints   Green
Print textWave0[1][1][1]        prints   Green
Print textWave0[1][1][1][1]     prints   Green
Print textWave0[1][1][1][1][1]  prints   r
```

The first four examples print row 1 of column 0. Since waves may have up to four dimensions, the first four [1]'s act as dimension indices. The column, layer, and chunk indices were out of range and were clipped to a value of 0. Finally in the last example, we ran out of dimensions and got string indexing. **Warning**: Do not count on this behavior because future versions of Igor may support more than four dimensions.

The way to avoid the ambiguity between wave and string indexing is to use parentheses like so:

```
Print (textWave0[1])[1]         prints   r
```

String Assignment

You can assign values to string variables using string assignment. We have already seen the simplest case of this, assigning a literal string value to a string variable. You can also assign values to a subrange of a string variable, using string indexing. Once again, assume we create a string variable called s1 and assign a value to it as follows:

```
String s1="hello there"
```

Then,

```
s1[0,4]="hi";print s1           prints   hi there
s1[0,4]="greetings";print s1    prints   greetings there
s1[0,0]="j";print s1            prints   jello there
s1[0]="well ";print s1          prints   well hello there
s1[100000]=" jack";print s1     prints   hello there jack
s1[-100]="well ";print s1       prints   well hello there
```

When the s1[p1,p2]= syntax is used, the right-hand side of the string assignment *replaces* the subrange of the string variable identified by the left-hand side, after p1 and p2 are clipped to 0 to n.

When the s1[p]= syntax is used, the right-hand side of the string assignment *is inserted before* the character identified by p after p is limited to 0 to n.

The subrange assignment just described for string variables is not supported when a text wave is the destination. To assign a value to a range of a text wave element, you will need to create a temporary string variable. For example:

```
Make/O/T tw = {"Red", "Green", "Blue"}
String stmp= tw[1]
stmp[1,2]="XX"
tw[1]= stmp;

print tw[0],tw[1],tw[2]        prints    Red GXXen Blue
```

String Substitution Using $

Wherever Igor expects the literal *name* of an operand, such as the name of a wave, you can instead provide a string expression preceded by the $ character. The $ operator evaluates the string expression and returns the *value* as a *name*.

For example, the Make operation expects the name of the wave to be created. Assume we want to create a wave named wave0:

```
   Make wave0              // OK: wave0 is a literal name.

   Make $"wave0"           // OK: $"wave0" evaluates to wave0.

   String str = "wave0"
   Make str                // WRONG: This makes a wave named str.
   Make $str               // OK: $str evaluates to wave0.
```

$ is often used when you write a function which receives the name of a wave to be created as a parameter. Here is a trivial example:

```
Function MakeWave(w)
   String wName      // name of the wave

   Make $wName
End
```

We would invoke this function as follows:

```
MakeWave("wave0")
```

We use $ because we need a wave name but we have a string containing a wave name. If we omitted the $ and wrote:

```
   Make wName
```

Igor would make a wave whose name is wName, not on a wave whose name is wave0.

String substitution is capable of converting a string expression to a *single* name. It can not handle multiple names. For example, the following will *not* work:

```
String list = "wave0;wave1;wave2"
Display $list
```

See **Processing Lists of Waves** on page IV-174 for ways to accomplish this.

$ Precedence Issues In Commands

This section discusses issues that arise when using string substitution in assignment statements in the command line or in a macro. This is somewhat academic because modern Igor programming is done with user-defined functions. In user-defined functions, the ambiguity is removed through the use of "wave references" (described in **Accessing Waves in Functions** on page IV-65).

There is one case in which string substitution does not work as you might expect. Consider this example:

```
String str1 = "wave1"
wave2 = $str1 + 3
```

You might expect that this would cause Igor to set wave2 equal to the sum of wave1 and 3. Instead, it generates an "expected string expression" error. The reason is that Igor tries to concatenate str1 and 3 *before* doing the substitution implied by $. The + operator is also used to concatenate two string expressions, and it has higher precedence than the $ operator. Since str1 is a string but 3 is not, Igor cannot do the concatenation.

You can get around this problem by changing this wave assignment to one of the following:

```
wave2 = 3 + $str1
wave2 = ($str1) + 3
```

Both of these accomplish the desired effect of setting wave2 equal to the sum of wave1 and 3. Similarly,

```
wave2 = $str1 + $str2   // Igor sees "$(str1 + $str2)"
```

generates the same "expected string expression" error. The reason is that Igor is trying to concatenate str1 and $str2. $str2 is a name, not a string. The solution is:

```
wave2 = ($str1) + ($str2)  // sets wave2 to sum of two named waves
```

Another situation arises when using the $ operator and [. The [symbol can be used for either point indexing into a wave, or character indexing into a string. The commands

```
String wvName = "wave0"
$wvName[1,2] = wave1[p]    // sets two values in wave named "wave0"
```

are interpreted to mean that points 1 and 2 of wave0 are set values from wave1.

If you intended "$wvName[1,2] = wave1" to mean that a wave whose name comes from characters 1 and 2 of the wvName string ("av") has all of its values set from wave1, you must use parenthesis:

```
$(wvName[1,2]) = wave1     // sets all values of wave named "av"
```

String Utility Functions

WaveMetrics provides a number of handy utility functions for dealing with strings. To see a list of the built-in string functions, open the Igor Help Browser Command Help tab and then choose String from the pop-up menu of function categories. See also the string utility procedure files provided by WaveMetrics in the WaveMetrics Procedures:Utilities:String Utilities folder.

Special Cases

This section documents some techniques that were devised to handle certain specialized situations that arise with respect to Igor's command language.

Instance Notation

There is a problem that occurs when you have multiple instances of the same wave in a graph or multiple instances of the same object in a layout. For example, assume you want to graph yWave versus xWave0, xWave1, and xWave2. To do this, you need to execute:

```
Display yWave vs xWave0
AppendToGraph yWave vs xWave1
AppendToGraph yWave vs xWave2
```

The result is a graph in which yWave occurs three times. Now, if you try to remove or modify yWave using:

```
RemoveFromGraph yWave
```

or

```
ModifyGraph lsize(yWave)=2
```

Igor will always remove or modify the first instance of yWave.

Instance notation provides a way for you to specify a particular instance of a particular wave. In our example, the command

```
RemoveFromGraph yWave#2
```

will remove instance number 2 of yWave and

```
ModifyGraph lsize(yWave#2)=2
```

will modify instance number 2 of yWave. Instance numbers start from zero so "yWave" is equivalent to "yWave#0". Instance number 2 is the instance of yWave plotted versus xWave2 in our example.

Where necessary to avoid ambiguity, Igor operation dialogs (e.g., Modify Trace Appearance) automatically use instance notation. Operations that accept trace names (e.g., ModifyGraph) or layout object names (e.g., ModifyObject) accept instance notation.

A graph can also display multiple waves with the same name if the waves reside in different datafolders. Instance notation applies to the this case also.

Instance Notation and $

The $ operator can be used with instance notation. The # symbol may be either inside the string operand or may be outside. For example `$"wave0#1"` or `$"wave0"#1`. However, because the # symbol may be inside the string, the string must be parsed by Igor. Consequently, unlike other uses of $, the wave name portion must be surrounded by single quotes if liberal names are used. For example, suppose you have a wave with the liberal name of `'ww#1'` plotted twice. The first instance would be `$"'ww#1'"` and the second `$"'ww#1'#1"` whereas `$"ww#1"` would reference the second instance of the wave ww.

Object Indexing

The ModifyGraph, ModifyTable and ModifyLayout operations, used to modify graphs, tables and page layouts, each support another method of identifying the object to modify. This method, object indexing, is used to generate style macros (see **Graph Style Macros** on page II-300). You may also find it handy in other situations.

Normally, you need to know the name of the object that you want to modify. For example, assume that we have a graph with three traces in it and we want to set the traces' markers from a procedure. We can write:

```
ModifyGraph marker(wave0)=1, marker(wave1)=2, marker(wave2)=3
```

Because it uses the names of particular traces, this command is specific to a particular graph. What do we do if we want to write a command that will set the markers of three traces in *any* graph, regardless of the names of the traces? This is where object indexing comes in.

Using object indexing, we can write:

```
ModifyGraph marker[0]=1, marker[1]=2, marker[2]=3
```

This command sets the markers for the first three traces in a graph, no matter what their names are.

Indexes start from zero. For graphs, the object index refers to traces starting from the first trace placed in the graph. For tables the index refers to columns from left to right. For page layouts, the index refers to objects starting from the first object placed in the layout.

/Z Flag

The ModifyGraph marker command above works fine if you know that there *are* three waves in the graph. It will, however, generate an error if you use it on a graph with fewer than 3 waves. The ModifyGraph operation supports a flag that can be used to handle this:

```
ModifyGraph/Z marker[0]=1, marker[1]=2, marker[2]=3
```

The /Z flag ignores errors if the command tries to modify an object that doesn't exist. The /Z flag works with the SetAxis and Label operations as well as with the ModifyGraph, ModifyTable and ModifyLayout oper-

ations. Like object indexing, the /Z flag is primarily of use in creating style macros, which is done automatically, but it may come in handy for other uses.

Chapter
IV-2

Programming Overview

Overview

You can perform powerful data manipulation and analysis interactively using Igor's dialogs and the command line. However, if you want to automate common tasks or create custom numerical operations then you need to use procedures. You can write them yourself, use procedures supplied by WaveMetrics, or find someone else who has written procedures you can use. Even if you don't write procedures from scratch, it is useful to know enough about Igor programming to be able to understand code written by others.

Programming in Igor entails creating procedures by entering text in a procedure window. After entering a procedure, you can execute it via the command line, by choosing an item from a menu, or using a button in a control panel.

The bulk of the text in a procedure window falls into one of the following categories:

- Pragmas, which send instructions from the programmer to the Igor compiler
- Include statements, which open other procedure files
- Constants, which define symbols used in functions
- Structure definitions, which can be used in functions
- Proc Pictures, which define images used in control panels, graphs, and layouts
- Menu definitions, which add menu items or entire menus to Igor
- Functions — compiled code which is used for nearly all Igor programming
- Macros — interpreted code which, for the most part, is obsolete

Functions are written in Igor's programming language. Like conventional procedural languages such as C or Pascal, Igor's language includes:

- Data storage elements (variables, strings, waves)
- Assignment statements
- Flow control (conditionals and loops)
- Calls to built-in and external operations and functions
- Ability to define and call subroutines

Igor programming is easier than conventional programming because it is much more interactive — you can write a routine and test it right away. It is designed for interactive use within Igor rather than for creating stand-alone programs.

Organizing Procedures

Procedures can be stored in the built-in Procedure window or in separate auxiliary procedure files. Chapter III-13, **Procedure Windows**, explains how to edit the Procedure window and how to create auxiliary procedure files.

At first you will find it convenient to do all of your Igor programming in the built-in Procedure window. In the long run, however, it will be useful to organize your procedures into categories so that you can easily find and access general-purpose procedures and keep them separate from special-case procedures.

This table shows how we categorize procedures and how we store and access the different categories.

Category	What	Where	How
Experiment Procedures	These are specific to a single Igor experiment. They include procedures you write as well as window recreation macros created automatically when you close a graph, table, layout, control panel, or XOP target window (e.g., surface plot).	Usually experiment procedures are stored in the built-in Procedure window. You can optionally create additional procedure windows in a particular experiment but this is usually not needed.	You create an experiment procedure by typing in the built-in Procedure window.
Utility Procedures	These are general-purpose and potentially useful for any Igor experiment. WaveMetrics supplies utility procedures in the WaveMetrics Procedures folder. You can also write your own procedures or get them from colleagues.	WaveMetrics-supplied utility procedure files are stored in the WaveMetrics Procedures folder. Utility procedure files that you or other Igor users create should be stored in your own folder, in the Igor Pro User Files folder (see **Igor Pro User Files** on page II-46 for details) or at another location of your choosing. Place an alias or shortcut for your folder in "Igor Pro User Files/User Procedures".	Use an include statement to use a WaveMetrics or user utility procedure file. Include statements are described in **The Include Statement** on page IV-145.
Global Procedures	These are procedures that you want to be available from all experiments.	Store your global procedure files in "Igor Pro User Files/Igor Procedures" (see **Igor Pro User Files** on page II-46 for details). You can also store them in another folder of your choice and place an alias or shortcut for your folder in "Igor Pro User Files/Igor Procedures".	Igor automatically opens any procedure file in "Igor Pro Folder/Igor Procedures" and "Igor Pro User Files/Igor Procedures" and subfolders or referenced by an alias or shortcut in those folders, and leaves it open in all experiments.

Following this scheme, you will know where to put procedure files that you get from colleagues and where to look for them when you need them.

Utility and global procedures should be general-purpose so that they can be used from any experiment. Thus, they should not rely on specific waves, global variables, global strings, specific windows or any other objects specific to a particular experiment. See **Writing General-Purpose Procedures** on page IV-146 for further guidelines.

After they are debugged and thoroughly tested, you may want to share your procedures with other Igor users. If so, contact WaveMetrics for help in publicizing and distributing them.

WaveMetrics Procedure Files

WaveMetrics has created a large number of utility procedure files that you can use as building blocks. These files are stored in the WaveMetrics Procedures folder. They are described in the WM Procedures Index help file, which you can access through the Windows→Help Windows menu.

You access WaveMetrics procedure files using include statements. Include statements are explained under **The Include Statement** on page IV-145.

Using the Igor Help Browser, you can search the WaveMetrics Procedures folder to find examples of particular programming techniques.

Macros and Functions

There are two kinds of Igor procedures: **macros** and **functions**. They use similar syntax. The main difference between them is that Igor compiles user functions but interprets macros.

Because functions are compiled, they are dramatically faster than macros. Compilation also allows Igor to detect errors in functions when you write the function, whereas errors in macros are detected only when they are executed.

Macros are a legacy of Igor's early days. With rare exceptions, **all new programming should use functions**, not macros. To simplify the presentation of Igor programming, most discussion of macros is segregated into Chapter IV-4, **Macros**.

Scanning and Compiling Procedures

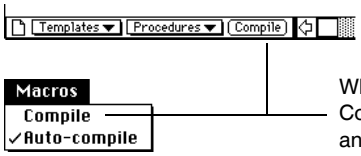
When you modify text in a procedure window, Igor must process it before you can execute any procedures. There are two parts to the processing: scanning and function compilation. In the scanning step, Igor finds out what procedures exist in the window. In the compilation step, Igor's function compiler converts the function text into low-level instructions for later execution.

During scanning, Igor makes the cursor look like scrolling text.

During compilation, Igor makes the cursor look like a meat grinder (text in, bits out).

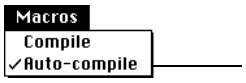
For the sake of brevity, we use the term "compile" to mean "scan and compile" except when we are specifically pointing out the distinction between these two steps.

You can *explicitly* compile the procedures using the Compile button in the Procedure window or the Compile item in the Macros menu.



By default, Igor *automatically* compiles the procedure text at appropriate times. For example, if you type in the Procedure window and then hide it by clicking in the close button, Igor will automatically compile.

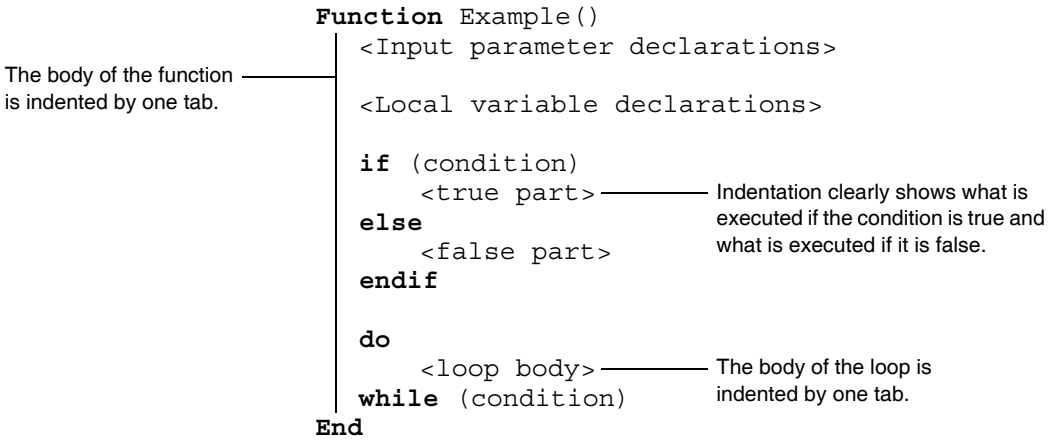
If you have many procedures that take long to compile, you may want to turn auto-compiling off using the Macros menu.



When Auto-compile is deselected, Igor compiles only when you explicitly request it. Igor will still scan the procedures when it needs to know what macros and functions exist.

Indentation Conventions

We use indentation to indicate the structure of a procedure.



The structural keywords, shown in bold here, control the flow of the procedure. The purpose of the indentation is to make the structure of the procedure apparent by showing which lines are within which structural keywords. Matching keywords are at the same level of indentation and all lines within those keywords are indented by one tab.

The Edit menu contains aids for maintaining or adjusting indentation. You can select multiple lines and choose Indent Left or Indent Right. You can have Igor automatically adjust the indentation of a procedure by selecting the whole procedure or a subset and then choosing Adjust Indentation.

Igor does not require that you use indentation but we recommend it for readability.

What's Next

The next chapter covers the core of Igor programming — writing user-defined functions.

Chapter IV-4, **Macros**, explains macros. Because new programming does not use macros, that chapter is mostly of use for understanding old Igor code.

Chapter IV-5, **User-Defined Menus**, explains user-defined menus. It explains how you can add menu items to existing Igor menus and create entire new menus of your own.

Chapter IV-6, **Interacting with the User**, explains other methods of interacting with the user, including the use of dialogs, control panels, and cursors.

Chapter IV-7, **Programming Techniques**, covers an assortment of programming topics. An especially important one is the use of the include statement, which you use to build procedures on top of existing procedures.

Chapter IV-8, **Debugging**, covers debugging using Igor's symbolic debugger.

Chapter IV-9, **Dependencies**, covers dependencies — a way to tie a variable or wave to a formula.

Chapter IV-10, **Advanced Programming**, covers advanced topics, such as communicating with other programs, doing FTP transfers, doing data acquisition, and creating a background task.

Chapter
IV-3

User-Defined Functions

Overview

Most of Igor programming consists of writing user-defined functions.

A function has zero or more numeric, string and wave parameters. You can use local variables to store intermediate results. The function body consists of Igor operations, assignment statements, flow control statements, and calls to other functions.

A function can return a numeric or string result. It can also have a side-effect, such as creating a wave or creating a graph.

Before we dive into the technical details, here is an informal look at some simple examples.

```
Function Hypotenuse(side1, side2)
   Variable side1, side2

   Variable hyp
   hyp = sqrt(side1^2 + side2^2)

   return hyp
End
```

The Hypotenuse function takes two numeric parameters and returns a numeric result. "hyp" is a local variable and sqrt is a built-in function. You could test Hypotenuse by executing the following statement in the command line:

```
Print Hypotenuse(3, 4)
```

Now let's look at a function that deals with text strings.

```
Function/S FirstStr(str1, str2)
   String str1, str2

   String result

   if (CmpStr(str1,str2) < 0)
      result = str1
   else
      result = str2
   endif

   return result
End
```

The FirstStr function takes two string parameters and returns the string that is first in alphabetical order. CmpStr is a built-in function. You could test FirstStr by executing the following statement in the command line:

```
Print FirstStr("ABC", "BCD")
```

Now a function that deals with waves.

```
Function CreateRatioOfWaves(w1, w2, nameOfOutputWave)
   WAVE w1, w2
   String nameOfOutputWave

   Duplicate/O w1, $nameOfOutputWave
   WAVE wOut = $nameOfOutputWave
   wOut = w1 / w2
End
```

The CreateRatioOfWaves function takes two wave parameters and a string parameter. The string is the name to use for a new wave, created by duplicating one of the input waves. The "`WAVE wOut`" statement creates a wave reference for use in the following assignment statement. This function has no direct result (no return statement) but has the side-effect of creating a new wave.

Here are some commands to test CreateRatioOfWaves:

```
Make test1 = {1, 2, 3}, test2 = {2, 3, 4}
CreateRatioOfWaves(test1, test2, "ratio")
Edit test1, test2, ratio
```

Function Syntax

The basic syntax of a function is:

```
Function <Name> (<Parameter list> [<Optional Parameters>]) [:<Subtype>]
   <Parameter declarations>

   <Local variable declarations>

   <Body code>

   <Return statement>
End
```

Here is an example:

```
Function Hypotenuse(side1, side2)
   Variable side1, side2            // Parameter declaration

   Variable hyp                     // Local variable declaration

   hyp = sqrt( side1^2 + side2^2 )  // Body code

   return hyp                       // Return statement
End
```

You could test this function from the command line using one of these commands:

```
Print Hypotenuse(3,4)
Variable/G result = Hypotenuse(3,4); Print result
```

As shown above, the function returns a real, numeric result. The Function keyword can be followed by a flag that specifies a different result type.

Flag	Return Value Type
/C	Complex number
/S	String
/D	Double precision number (obsolete)

The /D flag is obsolete because all calculations are now performed in double precision. However, it is still permitted.

The Function Name

The names of functions must follow the standard Igor naming conventions. Names can consist of up to 31 characters. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names must not conflict with the names of other Igor objects, functions or operations. Names in Igor are case insensitive.

The Procedure Subtype

You can identify procedures designed for specific purposes by using a subtype. Here is an example:

```
Function ButtonProc(ctrlName) : ButtonControl
   String ctrlName
```

```
   Beep
End
```

Here, "`: ButtonControl`" identifies a function intended to be called when a user-defined button control is clicked. Because of the subtype, this function is added to the menu of procedures that appears in the Button Control dialog. When Igor automatically generates a procedure it generates the appropriate subtype. See **Procedure Subtypes** on page IV-179 for details.

The Parameter List and Parameter Declarations

The parameter list specifies the name for each input parameter. There is no limit on the number of parameters.

All parameters must be declared immediately after the function declaration.

The parameter declaration must declare the type of each parameter using the keywords `Variable`, `String`, `WAVE` or `DFREF`.

If a parameter is a complex number, it must be declared `Variable/C`.

If it is a complex wave, it must be declared `WAVE/C`.

If it is a text wave, it must be declared `WAVE/T`.

Variable and string parameters are usually passed to a subroutine *by value* but can also be passed *by reference*. For an explanation of these terms, see **How Parameters Work** on page IV-44.

Optional Parameters

Following the list of required function input parameters, you can also specify a list of optional input parameters by enclosing the parameter names in brackets. You can supply any number of optional parameter values when calling the function by using the *`ParamName=Value`* syntax. Optional parameters may be of any valid data type. There is no limit on the number of parameters.

All optional parameters must be declared immediately after the function declaration. As with all other variables, optional parameters are initialized to zero. You must use the **ParamIsDefault** function to determine if a particular optional parameter was supplied in the function call.

See **Using Optional Parameters** on page IV-46 for an example.

Local Variable Declarations

The parameter declarations are followed by the local variable declarations if the procedure uses local variables. Local variables exist only during the execution of the procedure. They can be numeric or string and are declared using the `Variable` or `String` keywords. They can optionally be initialized. Here is an example:

```
Function Example(p1)
   Variable p1

   // Here are the local variables
   Variable v1, v2
   Variable v3=0
   Variable/C cv1=cmplx(0,0)
   String s1="test", s2="test2"

   <Body code>
End
```

If you do not supply explicit initialization, Igor automatically initializes local numeric variables with the value zero. Local string variables are initialized with a null value such that, if you try to use the string before you store a value in it, Igor will report an error.

The name of a local variable is allowed to conflict with other names in Igor although they must be unique within the function. Clearly if you create a local variable named "sin" then you will be unable to use Igor's built-in sin function within the function.

You can declare local variables in the body code section of a function as well as in the local variable section.

As of Igor Pro 5, you can define structures and use them as local variables in functions. Structures are defined outside of function definitions and are instantiated as local variables using the STRUCT keyword as described in **Structures in Functions** on page IV-78.

Body Code

This table shows what can appear in body code of a function.

What	Allowed in Functions?	Comment
Assignment statements	Yes	Includes wave, variable and string assignments.
Built-in operations	Yes, with a few exceptions.	See **Operations in Functions** on page IV-89 for exceptions.
Calls to user functions	Yes	
Calls to macros	No	
External functions	Yes	
External operations	Yes, with exceptions.	

As of Igor Pro 5, external operations can be designed to be directly callable from user-defined functions. External operations implemented by old XOPs can not be called directly.

The Execute operation provides a way to work around the limitation on what can be called from user functions. See **The Execute Operation** on page IV-176.

The Return Statement

A return statement often appears at the end of a function, but it can appear anywhere in the function body. You can also have more than one return statement.

The return statement immediately stops executing the function and returns a value to the calling function. If the function is declared as a string function (Function/S), then the return statement must return a string. Otherwise it must return a number.

If there is no return statement or if a function ends without hitting a return statement then the function returns the value NaN (Not a Number) for numeric functions and null for string functions. If the calling function attempts to use the null value, Igor will report an error.

Conditional Statements in Functions

Igor Pro supports two basic forms of conditional statements: if-else-endif and if-elseif-endif statements. Igor also supports multiway branching with switch and strswitch statements.

If-Else-Endif

The form of the if-else-endif structure is

```
if ( <expression> )
   <TRUE part>
else
   <FALSE part>
endif
```

<expression> is a numeric expression that is considered TRUE if it evaluates to any nonzero number and FALSE if it evaluates to zero. The TRUE part and the FALSE part may consist of any number of lines. If the expression evaluates to TRUE, only the TRUE part is executed and the FALSE part is skipped. If the expression evaluates to FALSE, only the FALSE part is executed and the true part is skipped. After the TRUE part or FALSE part code is executed, execution will continue with any code immediately following the if-else-endif statement.

The keyword "else" and the FALSE part may be omitted to give a simple conditional:

```
if ( <expression> )
   <TRUE part>
endif
```

Because Igor is line-oriented, you may not put the `if`, `else` and `endif` keywords all on the same line. They must each be in separate lines with no other code.

If-Elseif-Endif

The if-elseif-endif statement provides a means for creating nested if structures. It has the form:

```
if ( <expression1> )
   <TRUE part 1>
elseif ( <expression2> )
   <TRUE part 2>
[else
   <FALSE part>]
endif
```

These statements follow similar rules as for if-else-endif statements. When any expression evaluates as TRUE (nonzero) the code immediately following the expression will be executed. If all expressions evaluate as FALSE (zero) and there is an else clause, then the statements following the else keyword will be executed. Once any code in a TRUE part or the FALSE part is executed, execution will continue with any code immediately following the if-elseif-endif statement.

Comparisons

The relational comparison operators are used in numeric conditional expressions.

Symbol	Meaning	Symbol	Meaning
==	equal	<=	less than or equal
!=	not-equal	>	greater than
<	less than	>=	greater than or equal

These operators return 1 for TRUE and 0 for FALSE.

The comparison operators work with numeric operands only. To do comparisons with string operands, use the **cmpstr** function.

Comparison operators are usually used in conditional structures but can also be used in arithmetic expressions. For example:

```
wave0 = wave0 * (wave0 < 0)
```

This clips all positive values in wave0 to zero.

See also **Example: Comparison Operators and Wave Synthesis** on page II-98.

Bitwise and Logical Operators

The bitwise and logical operators are also used in conditional expressions.

Symbol	Meaning	Symbol	Meaning
~	Bitwise complement	!	Logical NOT
&	Bitwise AND	&&	Logical AND
|	Bitwise OR	||	Logical OR

The precedence of operators is shown in the table under **Operators** on page IV-5. In the absence of parentheses, an operator with higher precedence (higher in the table) is executed before an operator with lower precedence.

Because the precedence of the arithmetic operators is higher than the precedence of the comparison operators, you can write the following without parentheses:

```
if (a+b != c+d)
   Print "a+b is not equal to c+d"
endif
```

Because the precedence of the comparison operators is higher than the precedence of the logical OR operator, you can write the following without parentheses:

```
if (a==b || c==d)
   Print "Either a equals b or c equals d"
endif
```

For operators with the same precedence, there is no guaranteed order of execution and you must use parentheses to be sure of what will be executed. For example:

```
if ((a&b) != (c&d))
   Print "a ANDED with b is not equal to c ANDED with d"
endif
```

See **Operators** on page IV-5 for more discussion of operators.

Using Bitwise Operators

The bitwise operators are used to test, set, and clear bits. This makes sense only when you are dealing with integer operands.

Bit Action	Operation
Test	AND operator (&)
Set	OR operator (|)
Clear	Bitwise complement operator (~) followed by the bitwise AND operator (&)
Shift left	Multiply by powers of 2
Shift right	Divide by powers of 2

This function illustrates various bit manipulation techniques.

```
Function DemoBitManipulation(vIn)
   Variable vIn

   vIn = trunc(vIn)              // Makes sense with integers only
   Printf "Original value: %d\r", vIn

   Variable vOut
```

```
   if ((vIn & 2^3) != 0)         // Test if bit 3 is set
      Print "Bit 3 is set"
   else
      Print "Bit 3 is cleared"
   endif

   vOut = vIn | (2^3)            // Set bit 3
   Printf "Set bit 3: %d\r", vOut

   vOut = vIn & ~(2^3)           // Clear bit 3
   Printf "Clear bit 3: %d\r", vOut

   vOut = vIn * (2^3)            // Shift three bits left
   Printf "Shift three bits left: %d\r", vOut

   vOut = vIn / (2^3)            // Shift three bits right
   Printf "Shift three bits right: %d\r", vOut
End
```

For a simple demonstration, try this function passing 1 as the parameter.

In this example, 2^3 evaluates to 8 which is a value with only bit 3 set. In a real application, it is a good idea to define a constant that indicates the significance of the bit. These two statements are equivalent:

```
Constant kSystemReadyMask 8      // 8 specified in decimal notation

Constant kSystemReadyMask 0x08   // 8 specified in hexadecimal notation
```

Switch Statements

The switch construct can sometimes be used to simplify complicated flow control. It chooses one of several execution paths depending on a particular value.

Instead of a single form of switch statement, as is the case in C, Igor has two types: *switch* for numeric expressions and *strswitch* for string expressions. The basic syntax of these switch statements is as follows:

```
switch(<numeric expression>)        // numeric switch
   case <literal number or numeric constant>:
      <code>
      [break]
   case <literal number or numeric constant>:
      <code>
      [break]
   . . .
   [default:
      <code>]
endswitch

strswitch(<string expression>)      // string switch
   case <literal string or string constant>:
      <code>
      [break]
   case <literal string or string constant>:
      <code>
      [break]
   . . .
   [default:
      <code>]
endswitch
```

The switch numeric or string expression is evaluated and execution proceeds with the code following the matching case label. When none of the case labels match, execution will continue at the default label, if it is present, or otherwise the switch will exit with no action taken.

All of the case labels must be numeric or string constant expressions and they must all have unique values within the switch statement. The constant expressions can either be literal values or they must be declared using the constant and strconstant keywords for numeric and string switches, respectively. For more about constants, see **Constants** on page IV-40.

Execution proceeds within each case until a break statement is encountered or the endswitch is reached. The break statement explicitly exits the switch construct. Usually, you will put a break statement at the end of each case. If you omit the break statement, execution continues with the next case label. Do this when you want to execute a single action for more than one switch value.

The following examples illustrate how switch constructs can be used in Igor:

```
Constant kThree=3
StrConstant ksHow="how"

Function NumericSwitch(a)
   Variable a

   switch(a)                     // numeric switch
      case 1:
         print "a is 1"
         break
      case 2:
         print "a is 2"
         break
      case kThree:
      case 4:
         print "a is 3 or 4"
         break
      default:
         print "a is none of those"
         break
   endswitch
End

Function StringSwitch(a)
   String a

   strswitch(a)                  // string switch
      case "hello":
         print "a is hello"
         break
      case ksHow:
         print "a is how"
         break
      case "are":
      case "you":
         print "a is are or you"
         break
      default:
         print "a is none of those"
         break
   endswitch
End
```

Loops

Igor implements two basic types of looping structures: do-while and for loops. The do-while loop iterates through the loop code and tests an exit condition at the end of each iteration. The for loop is more complex; the beginning of a for loop includes expressions for initializing and updating variables as well as testing the loop's exit condition at the start of each iteration.

Do-While Loop

The form of the do-while loop structure is:

```
do
   <loop body>
while(<expression>)
```

This loop runs until the expression evaluates to zero or until a break statement is executed.

This example will always execute the body of the loop at least once, like the do-while loop in C.

```
Function Test(lim)
   Variable lim      // We use this parameter as the loop limit.

   Variable sum=0
   Variable i=0      // We use i as the loop variable.
   do
      sum += i       // This is the body; equivalent to sum=sum+i.
      i += 1         // Increment the loop variable.
   while(i < lim)
   return sum
End
```

Nested Do-While Loops

A nested loop is a loop within a loop. Here is an example:

```
Function NestedLoopTest(numOuterLoops, numInnerLoops)
   Variable numOuterLoops, numInnerLoops

   Variable i, j

   i = 0
   do
      j = 0
      do
         <inner loop body>
         j += 1
      while (j < numInnerLoops)
      i += 1
   while (i < numOuterLoops)
End
```

While Loop

This fragment will execute the body of the loop zero or more times, like the while loop in C.

```
do
   if (i > lim)
      break       // This breaks out of the loop.
   endif
   <loop body>
   i += 1
while(1)          // This would loop forever without the break.
...               // Execution continues here after the break.
```

In this example, the loop increment is 1 but it can be any value.

For Loop

The basic syntax of a for loop is:

```
for(<initialize>;<continue test>;<update>)
   <loop body>
endfor
```

Here is a simple example:

```
Function Example1()
   Variable i

   for(i=0;i<5;i+=1)
      print i
   endfor
End
```

The beginning of a for loop consists of three semicolon-separated expressions. The first is usually an assignment statement that initializes one or more variables. The second is a conditional expression used to determine if the loop should be terminated — if true, nonzero, the loop is executed; if false, zero, the loop terminates. The third expression usually updates one or more loop variables.

When a for loop executes, the initialization expression is evaluated only once at the beginning. Then, for each iteration of the loop, the continuation test is evaluated at the start of every iteration, terminating the loop if needed. The third expression is evaluated at the end of the iteration and usually increments the loop variable.

All three expressions in a for statement are optional and can be omitted independent of the others; only the two semicolons are required. The expressions can consist of multiple assignments, which must be separated by commas.

In addition to the test expression, for loops may also be terminated by break or return statements within the body of the loop. A continue statement executed within the loop skips the remaining body code and execution continues with the loop's update expression.

Here is a more complex example:

```
Function Example2()
   Variable i,j

   for(i=0,j=10; ;i+=1,j*=2)
      if( i==2 )
         continue
      endif
      Print i,j
      if( i==5 )
         break
      endif
   endfor
End
```

Break Statement

A break statement terminates execution of do-while loops, for loops, and switch statements. The break statement continues execution with the statement after the *enclosing* loop's while, endfor, or endswitch statement. A nested do-while loop example demonstrates this:

```
   …
   Variable i=0, j

   do                // Starts outer loop.
      if (i > numOuterLoops)
         break       // Break #1, exits from outer loop.
      endif
```

```
      j = 0
      do              // Start inner loop.
         if (j > numInnerLoops)
            break     // Break #2, exits from inner loop only.
         endif
         j += 1
      while (1)       // Ends inner loop.
      …               // Execution continues here from break #2.
      i += 1
   while (1)          // Ends outer loop.
   …                  // Execution continues here from break #1.
```

Continue Statement

The continue statement can be used in do-while and for loops to short-circuit the loop and return execution back to the top of the loop. When Igor encounters a continue statement during execution, none of the code following the continue statement is executed during that iteration.

Flow Control for Aborts

Igor Pro includes a specialized flow control construct and keywords that you can use to test for and respond to abort conditions. The AbortOnRTE and AbortOnValue keywords can be used to trigger aborts, and the try-catch-endtry construct can be used to control program execution when aborts occur. These are advanced techniques. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

AbortOnRTE Keyword

The AbortOnRTE keyword can be used to raise an abort whenever a runtime error occurs. Use AbortOnRTE immediately after (on the same line preceded by a semicolon) a command or on a line following a sequence of commands for which you wish to catch a runtime error.

See **AbortOnRTE** on page V-16 for further details. For a usage example see **try-catch-endtry Example** on page IV-39.

AbortOnValue Keyword

The AbortOnValue keyword can be used to abort function execution when a specified abort condition is satisfied. When AbortOnValue triggers an abort, it can also return a numeric abort code that you can use to characterize the cause.

AbortOnValue is a low overhead, short-hand replacement for an

```
if(abortTest)
   Abort
endif
```

code block that you would normally use in a procedure to test for an abort condition.

See **AbortOnValue** on page V-16 for further details. For a usage example see **try-catch-endtry Example** on page IV-39.

try-catch-endtry Flow Control

The try-catch-entry flow control construct has the following syntax:

```
try
   <possible abort code>
catch
   <code to handle abort>
endtry
```

The try-catch-entry flow control construct can be used to catch and respond to abort conditions in user functions. Code within the try-catch area tests for abort conditions and when the first abort condition is satisfied, execution will immediately jump to code within the catch-endtry area where execution proceeds with code to handle the abort condition. Normal flow (no aborts) will skip past all code within the catch-endtry area.

When an abort occurs within the try-catch area, the construct returns a numeric code in the V_AbortCode variable, which provides information about the cause of the abort.

See **try-catch-endtry** on page V-713 for further details.

try-catch-endtry Example

The following example demonstrates how abort flow control may be used. Copy the code to your Procedure window and execute the `foo` function with 0 to 6 as input parameters.

```
Function foo(a)
   Variable a

   print "A"
   try
      print "B1"
      AbortOnValue  a==1 || a==2,33
      print "B2"
      bar(a)
      print "B3"
      try
         print "C1"
         if( a==4 || a==5 )
            Make $""; AbortOnRTE
         endif
         Print "C2"
      catch
         Print "D1"
         // will be runtime error so pass along to outer catch
         AbortOnValue a==5, V_AbortCode
         Print "D2"
      endtry
      Print "B4"
      if( a==6 )
         do
         while(1)
      endif
      Print "B5"
   catch
      print "Abort code= ", V_AbortCode
      if( V_AbortCode == -4 )
         Print "Runtime error= ", GetRTError(1)
      endif
      if( a==1 )
         abort "Aborting again"
      endif
      Print "E"
   endtry
   print "F"
End

Function bar(b)
   Variable b

   Print "Bar A"
   AbortOnValue b==3,99
```

```
   Print "Bar B"
End
```

Constants

You can define named numeric and string constants in Igor procedure files and use them in the body of user-defined functions.

Constants are defined in procedure files using following syntax:

```
Constant <name1> = <literal number> [, <name2> = <literal number>]
StrConstant <name1> = <literal string> [, <name2> = <literal string>]
```

For example:

```
Constant kIgorStartYear=1989,kIgorEndYear=2020
StrConstant ksPlatformMac="Macintosh",ksPlatformWin="Windows"

Function Test1()
   Variable v1 = kIgorStartYear
   String s1 = ksPlatformMac
   Print v1, s1
End
```

Constants declared like this are public and can be used in any function in any procedure file. A typical use would be to define constants in a utility procedure file that could be used from other procedure files as parameters to the utility routines. Be sure to use precise names to avoid conflicts with public constants declared in other procedure files.

If you are defining constants for use in a single procedure file, for example to improve readability or make the procedures more maintainable, you should use the `static` keyword (see **Static** on page V-594 for details) to limit the scope to the given procedure file.

```
static Constant kStart=1989,kEnd=2020
static StrConstant ksMac="Macintosh",ksWin="Windows"
```

We suggest that you use the “k” prefix for numeric constants and the “ks” prefix for string constants. This makes it immediately clear that a particular keyword is a constant.

Names for numeric and string constants are allowed to conflict with all other names. Duplicate constants of a given type are not allowed (except static in different files and when used with the override keyword). The only true conflict is with variable names and with certain built-in functions that do not take parameters such as pi. Variable names (including local variable names, waves, NVARs, and SVARs) override constants, but constants override functions such as pi.

Pragmas

A pragma is a statement in a procedure file that sets a compiler mode or passes other information from the programmer to Igor. The form of a pragma statement is:

```
#pragma keyword [= parameter]
```

The pragma statement must be flush against the left margin of the procedure window, with no indentation.

Currently, Igor supports the following pragmas:

```
#pragma rtGlobals = value
#pragma version = versionNumber
#pragma IgorVersion = versionNumber
#pragma ModuleName = name
#pragma IndependentModule = name
```

The effect of a pragma statement lasts until the end of the procedure file that contains it.

The rtGlobals Pragma

The rtGlobals pragma controls aspects of the Igor compiler and runtime error checking in user-defined functions.

Prior to Igor Pro 3, to access a global (wave or variable) from a user-defined function, the global had to already exist. Igor Pro 3 introduced "runtime lookup of globals" under which the Igor compiler did not require globals to exist at compile time but rather connected references, declared with WAVE, NVAR and SVAR statements, to globals at runtime. Igor Pro 6.20 introduced stricter compilation of wave references and runtime checking of wave index bounds.

You enable and disable these behaviors using an rtGlobals pragma. For example:

```
#pragma rtGlobals = 3   // Strict wave reference mode, runtime bounds checking
```

A given rtGlobals pragma governs just the procedure file in which it appears. The pragma must be flush left in the procedure file and is typically put at the top of the file.

The rtGlobals pragma is defined as follows:

#pragma rtGlobals=0	Specifies the old, pre-Igor Pro 3 behavior. This is obsolete and should not be used.
#pragma rtGlobals=1	Turns on runtime lookup of globals. In Igor Pro 5 or later, this is the default setting if there is no rtGlobals pragma in a given procedure file.
#pragma rtGlobals=2	Forces old experiments out of compatibility mode. This is superceded by rtGlobals=3. It is described under **Legacy Code Issues** on page IV-90.
#pragma rtGlobals=3	Turns on runtime lookup of globals, strict wave references and runtime checking of wave index bounds. Requires Igor Pro 6.2 or later.

If your procedures will run only with Igor Pro 6.20 or later, rtGlobals=3 is recommended. Otherwise rtGlobals=1 is recommended.

If your procedures must run with old Igor versions but you want to use rtGlobals=3 when possible, you can do this:

```
#if IgorVersion() >= 6.20
#pragma rtGlobals = 3   // Strict wave reference mode, runtime bounds checking
#endif
```

Since rtGlobals=1 is the default, this will use rtGlobals=1 for Igor Pro 6.02A through 6.12 and will use rtGlobals=3 for Igor Pro 6.20 or later. It will not work for versions prior to 6.02A because they don't support conditional compilation (#if).

Under strict wave references (rtGlobals=3), you must create a wave reference for any use of a wave. Without strict wave references (rtGlobals=1), you do not need to create a wave reference unless the wave is used in an assignment statement. For example:

```
Function Test()
   jack = 0       // Error under rtGlobals=1 and under rtGlobals=3
   Display jack   // OK under rtGlobals=1, error under rtGlobals=3

   Wave jack      // jack is now a wave reference rather than a bare name
   Display jack   // OK under rtGlobals=1 and under rtGlobals=3
End
```

Even with rtGlobals=3, this compiles without error:

```
Function Test()
   // Make creates an automatic wave reference when used with a simple name
   Make jack
```

```
   Display jack   // OK under rtGlobals=1 and rtGlobals=3
End
```

See **Automatic Creation of WAVE References** on page IV-56 for details.

Under runtime wave index checking (rtGlobals=3), Igor reports an error if a wave index is out-of-bounds:

```
Function Test()
   Make/O/N=5 jack = 0  // Creates automatic wave reference

   jack[4] = 123        // OK
   jack[5] = 234        // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.

   Variable index = 5
   jack[index] = 234    // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.

   // Create and use a dimension label for point 4 of jack
   SetDimLabel 0,4,four,jack
   jack[%four] = 234    // OK

   // Use a non-existent dimension label.
   jack[%three] = 345   // Runtime error under rtGlobals=3.
                        // Clipped under rtGlobals=1.
   // Under rtGlobals=1, this statement writes to point 0 of jack.
End
```

NOTE: All Igor documentation assumes that rtGlobals=1 is in effect unless otherwise stated.

The version Pragma

The version pragma sets the version of the procedure file. It is optional and is of interest mostly if you are the developer of a package used by a widespread group of users.

For details on the version pragma, see **Procedure File Version Information** on page IV-145.

The IgorVersion Pragma

The IgorVersion pragma is also optional and of interest to developers of packages. It gives you a way to prevent procedures from running, or at least generating compilation errors that cannot be fixed, under versions of Igor Pro older than the specified version number.

For example, the statement:

```
#pragma IgorVersion = 4.0
```

requires Igor Pro 4.0 or later for the procedure file. This will be helpful if you share your code with others because you can ensure that your procedures will only run with versions of Igor Pro that fully support all of the new or updated features you may have used. This Igor version check was added with Igor Pro 4.0, and it will not work with previous versions.

The ModuleName Pragma

The ModuleName pragma gives you the ability to use static functions and Proc Pictures in a global context, such as in the action procedure of a control or on the Command Line. Using this pragma entails a two step process: define a name for the procedure file, and then use a special syntax to access objects in the named procedure file.

To define a module name for a procedure file use the format:

```
#pragma ModuleName= name
```

This statement associates the specified module name with the procedure file in which the statement appears.

You can then use objects from the named procedure file by preceding the object name with the name of the module and the # character. For example:

```
#pragma ModuleName= myGreatProcedure

Static Function foo(a)
   Variable a

   return a+100
End
```

Then on the command line you can execute:

```
Print myGreatProcedure#foo(3)
```

You should make sure the name is unlikely to clash with other names you or others might use. WaveMetrics will use names with a `WM_` prefix, so you should avoid such names. The ModuleName pragma will not work with versions previous to Igor Pro 5.0.

For further discussion see **Regular Modules** on page IV-212.

The IndependentModule Pragma

The IndependentModule pragma is a way for you to designate groups of one or more procedure files that are compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows functioning control panels and menus to continue to work regardless of user programming errors.

A file is designated as an independent module using

```
#pragma IndependentModule=imName
```

This is similar to `#pragma ModuleName=`*modName* (see **The ModuleName Pragma** on page IV-42) and, just as in the case of calling static functions in a procedure with #pragma ModuleName, calling nonstatic function in an IndependentModule from outside the module requires the use of *imName#functionName*() syntax.

For further discussion see **Independent Modules** on page IV-214.

Unknown Pragmas

Starting with Igor Pro version 3.04, Igor ignores pragmas that it does not know about. This allows newer versions of Igor to use new pragmas while older versions ignore them. The downside of this change is that, if you misspell a pragma keyword, Igor will not warn you about it.

Proc Pictures

Proc Pictures are binary PNG or JPEG images encoded as printable ASCII procedures in procedure files. They are intended for programmers who need images as part of the user interface for a procedure package. They can be used with the **DrawPICT** operation (see page V-128) and with the **Picture** keyword (see page V-480) in certain controls.

The syntax for defining and using a Proc Picture is illustrated in the following example:

```
// PNG: width= 56, height= 44
Picture myPictName
   ASCII85Begin
   M,6r;%14!\!!!!.8Ou6I!!!!Y!!!!M#Qau+!5G;q_uKc;&TgHDFAm*iFE_/6AH5;7DfQssEc39jTBQ
   =U!7FG,5u`*!m?g0PK.mR"U!k63rtBW)]$T)Q*!=Sa1TCDV*V+l:Lh^NW!fu1>;(.<VU1bs4L8&@Q_
```

```
   <4e(%"^F50:Jg6);j!CQdUA[dh6]%[OkHSC,ht+Q7ZO#.6U,IgfSZ!R1g':oO_iLF.GQ@RF[/*G98D
   bjE.g?NCte(pX-($m^\_FhhfL`D9uO6Qi5c[r4849Fc7+*)*O[tY(6<rkm^)/KLIc]VdDEbF-n5&Am
   2^hbTu:U#8ies_W<LGkp_LEU1bs4L8&?fqRJ[h#sVSSz8OZBBY!QNJ
   ASCII85End
End

Function test()
   NewPanel
   DrawPict 0,0,1,1,ProcGlobal#myPictName
End
```

The ASCII text in the `myPictName` procedure between the `ASCII85Begin` and `ASCII85End` is similar to output from the Unix `btoa` command or, on Macintosh, StuffIt's binary to ASCII operation. (You must remove any extra header and trailer information if you use either of these utilities to create a Proc Picture.)

You can create Proc Pictures in Igor Pro from normal, global pictures using the Picture dialog (see **Pictures** on page III-421). Select a picture in the dialog and click the Copy Proc Picture button to place the text on the Clipboard and then paste it in your procedure file. If the existing picture is not a JPEG or PNG, it is converted to PNG.

Proc Pictures can be either global or local in scope. Global pictures can be used in all experiment procedure files; local pictures can be used only within the procedure file where they are defined. Proc Pictures are global by default and the picture name must be unique for all procedure files in an experiment. Proc Pictures can be made local in scope by declaring them Static (see **Static** on page V-594).

When accessing a Proc Picture from DrawPict, the picture name must be preceded by either the `ProcGlobal` keyword or the procedure module name, and the two names joined together with `#`. This naming convention is necessary to avoid potential conflicts with any existing experiment global pictures defined via the Pictures dialog.

For a global Proc Picture, you must use the `ProcGlobal` keyword as the prefix:

`ProcGlobal#`*`gProcPictName`*

For a static Proc Picture, you must use the module name defined in the procedure file by the `#pragma ModuleName = `*`modName`* statement (see **ModuleName** on page V-424) as the prefix:

`modName``#`*`ProcPictName`*

How Parameters Work

There are two ways of passing parameters from a routine to a subroutine: **pass-by-value** and **pass-by-reference**. "Pass-by-value" means that the routine passes the *value* of an expression to the subroutine. "Pass-by-reference" means that the routine passes *access to a variable* to the subroutine. The important difference is that, in pass-by-reference, the subroutine can change the original variable in the calling routine.

The C and Pascal languages allow programmers to use either of these techniques, at their option while FORTRAN uses pass-by-reference only. Like C, Igor also allows either method for numeric and string variables.

Example of Pass-By-Value

```
Function Routine()
   Variable v = 4321
   String s = "Hello"

   Subroutine(v, s)
End

Function Subroutine(v, s)
   Variable v
   String s

   Print v, s
```

```
   // These lines have NO EFFECT on the calling routine.
   v = 1234
   s = "Goodbye"
End
```

Note that v and s are *local variables* in Routine. In Subroutine, they are *parameters* which act very much like local variables. The names "v" and "s" are local to the respective functions. The v in Subroutine is not the same variable as the v in Routine although it initially has the same value.

The last two lines of Subroutine set the value of the local variables v and s. They have no effect on the value of the variables v and s in the calling Routine. What is passed to Subroutine is the numeric value 4321 and the string value "Hello".

Pass-By-Reference

You can specify that a parameter to a function is to be passed by reference rather than by value. In this way, the function called can change the value of the parameter and update it in the calling function. This is much like using pointers to arguments in C. This technique is needed and appropriate only when you need to return more than one value from a function.

The variable or string being passed must be a local variable and can not be a global variable. To designate a variable or string parameter for pass-by-reference, simply prepend an ampersand symbol (&) before the name in the parameter declaration:

```
Function Subroutine(num1,num2,str1)
   Variable &num1, num2
   String &str1

   num1= 12+num2
   str1= "The number is"
End
```

and then call the function with the name of a local variable in the reference slot:

```
Function Routine()
   Variable num= 1000
   String str= "hello"
   Subroutine(num,2,str)
   print str, num
End
```

When executed, Routine prints "The number is 14" rather than "hello 1000", which would be the case if pass-by-reference were not used.

A pass-by-reference parameter can be passed to another function that expects a reference:

```
Function SubSubroutine(b)
   Variable &b
   b= 123
End

Function Subroutine(a)
   Variable &a
   SubSubroutine(a)
End

Function Routine()
   Variable num
   Subroutine(num)
   print num
End
```

Note: Functions with pass-by-reference parameters can only be called from other functions — not from the command line.

How Waves Are Passed

Here is an example of a function "passing a wave" to a subroutine.

```
Function Routine()
   Make/O wave0 = x
   Subroutine(wave0)
End

Function Subroutine(w)
   WAVE w

   w = 1234    // This line DOES AFFECT the wave referred to by w.
End
```

We are really not passing a wave to Subroutine, but rather we are passing a reference to a wave. The parameter `w` is the wave reference.

Waves are global objects that exist independent of functions. The subroutine can use the wave reference to modify the contents of the wave. Using the terminology of "pass-by-value" and "pass-by-reference", the wave reference is passed by value, but this has the effect of "passing the wave" by reference.

Using Optional Parameters

Following is an example of a function with two optional input parameters:

```
Function opParamTest(a,b, [c,d])
   Variable a,b,c,d           // c and d are optional parameters

   // Determine if the optional parameters were supplied
   if( ParamIsDefault(c) && ParamIsDefault(d) )
      Print "Missing optional parameters c and d."
   endif

   Print a,b,c,d
End
```

Executing on the Command Line with none of the optional inputs:

```
•opParamTest(8,6)
  Missing optional parameters c and d.
  8  6  0  0
```

Executing with an optional parameter as an input:

```
•opParamTest(8,6, c=66)
  8  6  66  0
```

Note that the optional parameter is explicitly defined in the function call using the *ParamName=Value* syntax. All optional parameters must come after any required function parameters.

Local Versus Global Variables

Numeric and string variables can be **local** or **global**. "Local" means that the variable can be accessed only from within the procedure in which it was created. "Global" means that the variable can be accessed from the command line or from within any procedure. The following table shows the characteristics of local and global variables:

Local Variables	Global Variables
Are part of a procedure.	Are part of an Igor experiment.
Created using Variable or String within a procedure.	Created using Variable or String or Variable/G or String/G from the command line or within a procedure.

Local Variables	Global Variables
Used to store temporary results while the procedure is executing.	Used to store values that are saved from one procedure invocation to the next or to store data that is accessed by many procedures.
Cease to exist when the procedure ends.	Exist until you use KillVariables, KillStrings, or KillDataFolder.
Can be accessed only from within the procedure in which they were created.	Can be accessed from the command line or from within any procedure.

Local variables are private to the function in which they are declared and vanish when the function exits. Global variables are public and persistent — they exist until you explicitly delete them.

If you write a function whose main purpose is to display a dialog to solicit input from the user, you may want to store the user's choices in global variables and use them to initialize the dialog the next time the user invokes it. This is an example of saving values from one invocation of a function to the next.

If you write a set of functions that loads, displays and analyzes experimentally acquired data, you may want to use global variables to store values that describe the conditions under which the data was acquired and to store the results from the analyses. These are examples of data accessed by many procedures.

Local Variables Used by Igor Operations

When invoked from a function, a number of Igor's operations return results via local variables. For example, the WaveStats operation creates a number of local variables with names such as V_avg, V_sigma, etc. The following function illustrates this point.

```
Function PrintWaveAverage(w)
   WAVE w

   WaveStats/Q w
   Print V_avg
End
```

When the Igor compiler compiles the WaveStats operation, it creates various local variables, V_avg among them. When the WaveStats operation runs, it stores results in these local variables.

In addition to creating local variables, a few operations, such as CurveFit and FuncFit, check for the existence of specific local variables to provide optional behavior. For example:

```
Function ExpFitWithMaxIterations(w, maxIterations)
   WAVE w
   Variable maxIterations

   Variable V_FitMaxIters = maxIterations

   CurveFit exp w
End
```

The CurveFit operation looks for a local variable named V_FitMaxIters, which sets the maximum number of iterations before the operation gives up.

The documentation for each operation lists the special variables that it creates or looks for.

Converting a String into a Reference Using $

The $ operator converts a string expression into an object reference. The referenced object is usually a wave but can also be a global numeric or global string variable, a window, a symbolic path or a function. This is a common and important technique.

We often use a *string* to pass the *name* of a wave to a procedure or to algorithmically generate the name of a wave. Then we use the $ operator to convert the string into a wave reference so that we can operate on the wave.

The following trivial example shows why we need to use the $ operator:

```
Function DisplayXY(xWaveNameStr, yWaveNameStr)
   String xWaveNameStr, yWaveNameStr

   Display $yWaveNameStr vs $xWaveNameStr
End
```

Here we use $ to convert the string parameters into wave references. The function will display the wave whose name is stored in the yWaveNameStr string versus the wave whose name is stored in the xWaveNameStr string.

If we omitted the $ operators, we would have

```
Display yWaveNameStr vs xWaveNameStr
```

This would result in an error because the Display operation would look for a wave named yWaveName and would not find it.

As shown in the following example, $ can create references to global numeric and string variables as well as to waves.

```
Function Test(vStr, sStr, wStr)
   String vStr, sStr, wStr

   NVAR v = $vStr       // v is local name for global numeric var
   v += 1
   SVAR s = $sStr       // s is local name for global string var
   s  += "Hello"
   WAVE w = $wStr       // w is local name for global wave
   w += 1
End

Variable/G gVar = 0; String/G gStr = ""; Make/O/N=5 gWave = p
Test("gVar", "gStr", "gWave")
```

The NVAR, SVAR and WAVE references are necessary in functions so that the compiler can identify the kind of object. This is explained under **Accessing Global Variables and Waves** on page IV-50.

Using $ to Refer to a Window

A number of Igor operations modify or create windows, and optionally take the name of a window. You need to use a string variable if the window name is not determined until run time but must convert the string into a name using $.

For instance, this function creates a graph using a name specified by the calling function:

```
Function DisplayXY(xWaveNameStr, yWaveNameStr, graphNameStr)
   String xWaveNameStr, yWaveNameStr
   String graphNameStr     // Contains name to use for the new graph

   Display /N=$graphNameStr $yWaveNameStr vs $xWaveNameStr
   Cursor /W=$graphNameStr A, $yWaveNameStr, 0
End
```

The $ operator in /N=$graphNameStr converts the contents of the string graphNameStr into a graph name as required by the Display operation /N flag. If you forget $, the command would be:

```
   Display /N=graphNameStr $yWaveNameStr vs $xWaveNameStr
```

This would create a graph literally named graphNameStr.

After creating the graph, this example uses $graphNameStr again to specify the target of the Cursor operation.

Using $ In a Data Folder Path

$ can also be used to convert a string to a name in a data folder path. This is used when one of many data folders must be selected algorithmically.

Assume you have a string variable named dfName that tells you in which data folder a wave should be created. You can write:

```
Make/O root:$(dfName):wave0
```

The parentheses are necessary because the $ operator has low precedence, so Igor would interpret this:

```
Make/O root:$dfName:wave0            // ERROR
```

to mean:

```
Make/O root:$(dfName:wave0)          // ERROR
```

To avoid this, you must use parentheses like this:

```
Make/O root:$(dfName):wave0          // OK
```

Compile Time Versus Runtime

Because Igor user-defined functions are compiled, you need to be aware of the difference between "compile time" and "runtime".

Compile time is when Igor analyzes the text of all functions and produces low-level instructions that can be executed quickly later. This happens when you modify a procedure window and then:

- Choose Compile from the Macros menu.
- Click the Compile button at the bottom of a procedure window.
- Activate a nonprocedure window.

Runtime is when Igor actually executes a function's low-level instructions. This happens when:

- You invoke the function from the command line.
- The function is invoked from another procedure.
- Igor updates a dependency which calls the function.
- You use a button or other control that calls the function.

Conditions that exist at compile time are different from those at runtime. For example, a function can reference a global variable. The global does not need to exist at compile time, but it does need to exist at runtime. This issue is discussed in detail in the following sections.

Here is another example of the distinction between compile time and runtime:

```
Function Example(w)
   WAVE w

   w= sin(x)
   FFT w
   w= r2polar(w)
End
```

The declaration "`WAVE w`" specifies that w is expected to be a real wave. This is correct until the FFT executes and thus the first wave assignment produces the correct result. After the FFT is executed at runtime, however, the wave becomes complex. The Igor compiler does not know this and so it will compile the second wave assignment on the assumption that w is real. A compile-time error will be generated com-

plaining that r2polar is not available for this number type — i.e., real. To provide Igor with the information that the wave is complex after the FFT you need to rewrite the function like this:

```
Function Example(w)
   WAVE w

   w= sin(x)
   FFT w
   WAVE/C wc= w
   wc= r2polar(wc)
End
```

A statement like "`WAVE/C wc= w`" has the compile-time behavior of creating a symbol, wc, and specifying that it refers to a complex wave. It has the runtime behavior of making wc refer to a specific wave. The runtime behavior can not occur at compile time because the wave may not exist at compile time.

Accessing Global Variables and Waves

Global numeric variables, global string variables and waves can be referenced from any function. A function can refer to a global that does not exist at compile-time. For the Igor compiler to know what type of global you are trying to reference, you need to declare references to globals.

Consider the following function:

```
Function BadExample()
   gStr1 = "The answer is:"
   gNum1 = 1.234
   wave0 = 0
End
```

The compiler can not compile this because it doesn't know what gStr1, gNum1 and wave0 are. We need to specify that they are a global string variable, a global numeric variable and a wave, respectively:

```
Function GoodExample1()
   SVAR gStr1 = root:gStr1
   NVAR gNum1 = root:gNum1
   WAVE wave0 = root:wave0

   gStr1 = "The answer is:"
   gNum1 = 1.234
   wave0 = 0
End
```

The SVAR statement specifies two important things for the compiler: first, that gStr1 is a global string variable; second, that gStr1 refers to a global string variable named gStr1 in the root data folder. Similarly, the NVAR statement identifies gNum1 and the WAVE statement identifies wave0. With this knowledge, the compiler can compile the function.

The technique illustrated here is called "runtime lookup of globals" because the compiler compiles code that associates the symbols gStr1, gNum1 and wave0 with specific global variables at runtime.

Runtime Lookup of Globals

The syntax for runtime lookup of globals is:

```
NVAR <local name1>[= <path to var1>][, <loc name2>[= <path to var2>]]…
SVAR <local name1>[= <path to str1>][, <loc name2>[= <path to str2>]]…
WAVE <local name1>[= <path to wave1>][, <loc name2>[= <path to wave2>]]…
```

NVAR and SVAR create a reference to a global numeric or string variable and WAVE creates a reference to a wave. At compile time, these statements identify the referenced objects. At runtime, the connection is made between the local name and the actual object. Consequently, the object must exist when these statements are executed.

<local name> is the name by which the global variable, string or wave is to be known within the user function. It does not need to be the same as the name of the global variable. The example function could be rewritten as follows:

```
Function GoodExample2()
   SVAR str1 = root:gStr1     // str1 is the local name.
   NVAR num1 = root:gNum1     // num1 is the local name.
   WAVE w = root:wave0        // w is the local name.

   str1 = "The answer is:"
   num1 = 1.234
   w = 0
End
```

If you use a local name that is the same as the global name, and if you want to refer to a global in the current data folder, you can omit the <path to …> part of the declaration:

```
Function GoodExample3()
   SVAR gStr1           // Refers to gStr1 in current data folder.
   NVAR gNum1           // Refers to gNum1 in current data folder.
   WAVE wave0           // Refers to wave0 in current data folder.

   gStr1 = "The answer is:"
   gNum1 = 1.234
   wave0 = 0
End
```

GoodExample3 accesses globals in the current data folder while GoodExample2 accesses globals in a specific data folder.

If you use <path to …>, it may be a simple name (gStr1) or it may include a full or partial path to the name.

The following are valid examples, referencing a global numeric variable named gAvg:

```
   NVAR gAvg= gAvg
   NVAR avg= gAvg
   NVAR gAvg
   NVAR avg= root:Packages:MyPackage:gAvg
   NVAR avg= :SubDataFolder:gAvg
   NVAR avg= $"gAvg"
   NVAR avg= $("g"+ "Avg")
   NVAR avg= ::$"gAvg"
```

As illustrated above, the local name can be the same as the name of the global object and the lookup expression can be either a literal name or can be computed at runtime using $<string expression>.

In some cases, it may be convenient to create global variables in a temporary data folder as a way of passing results back to the calling routine. For example:

```
Function MyWaveStats(inputWave)
   WAVE inputWave

   NewDataFolder/O/S tmpMyWaveStatsDF

   WaveStats/Q inputWave

   Variable/G gNumPoints = V_npnts
   Variable/G gAvg = V_avg
   Variable/G gSdev = V_sdev
End

Function Test()
   Make/O testwave= gnoise(1)

   MyWaveStats(testwave)      // Create temp output data folder.
```

```
   NVAR gNumPoints,gAvg,gSdev // Create references to globals.
   Printf "Points: %g; Avg: %g; SDev: %g\r", gNumPoints,gAvg,gSdev
   KillDataFolder :           // Kill temp output data folder.
End
```

Note that the NVAR statement must appear after the MyWaveStats call because NVAR associates the local names with existing global variables at runtime.

Put WAVE Declaration After Wave Is Created

A wave declaration serves two purposes. At compile time, it tells Igor the local name and type of the wave. At runtime, it connects the local name to the wave. In order for the runtime purpose to work, you must put wave declaration after the wave is created.

```
Function BadExample()
   String path = "root:Packages:MyPackage:wave0"
   Wave w = $path          // WRONG: Wave does not yet exist.
   Make $path
   w = p                   // w is not connected to any wave.
End

Function GoodExample()
   String path = "root:Packages:MyPackage:wave0"
   Make $path
   Wave w = $path          // RIGHT
   w = p
End
```

Both of these functions will successfully compile. BadExample will fail at runtime because w is not associated with a wave, because the wave does not exist when the "Wave w = $path" statement executes.

This rule also applies to NVAR and SVAR declarations.

Runtime Lookup Failure

At runtime, it is possible that a NVAR, SVAR or WAVE statement may fail. For example, `NVAR v1= var1` will fail if var1 does not exist in the current data folder when the statement is executed. You can use the NVAR_Exists, SVAR_Exists, and WaveExists functions to test if a given global reference is valid.

One cause for failure is putting a WAVE statement in the wrong place. For example:

```
Function BadExample()
   WAVE w = resultWave
   <Call a function that creates a wave named resultWave>
   Display w
End
```

This function will compile successfully but will fail at runtime. The reason is that the "`WAVE w = resultWave`" statement has the runtime behavior of associating the local name w with a particular wave. But that wave does not exist until the following statement is executed. The function should be rewritten as:

```
Function GoodExample()
   <Call a function that creates a wave named resultWave>
   WAVE w = resultWave
   Display w
End
```

Runtime Lookup Failure and the Debugger

You can break whenever a runtime lookup fails using the symbolic debugger (described in Chapter IV-8, **Debugging**). It is a good idea to do this, because it lets you know about runtime lookup failures at the moment they occur.

Sometimes you may create a WAVE, NVAR or SVAR reference knowing that the referenced global may not exist at runtime. Here is a trivial example:

```
Function Test()
   WAVE w = testWave
   if (WaveExists(testWave))
      Printf "testWave had %d points.\r", numpnts(testWave)
   endif
End
```

If you enable the debugger's WAVE checking and if you execute the function when testWave does not exist, the debugger will break and flag that the WAVE reference failed. But you wrote the function to handle this situation, so the debugger break is not helpful in this case.

The solution is to rewrite the function using WAVE/Z instead of just WAVE. The /Z flag specifies that you know that the runtime lookup may fail and that you don't want to break if it does. You can use NVAR/Z and SVAR/Z in a similar fashion.

Accessing Complex Global Variables and Waves

You must specify if a global numeric variable or a wave is complex using the /C flag:

```
NVAR/C gc1= gc1
WAVE/C gcw1= gcw1
```

Accessing Text Waves

Text waves must be accessed using the /T flag:

```
WAVE/T tw= MyTextWave
```

Accessing Global Variables and Waves Using Liberal Names

There are two ways to reference an Igor object: using a literal name or path or using a string variable. For example:

```
Wave w = root:MyDataFolder:MyWave   // Using literal path
String path = "root:MyDataFolder:MyWave"
Wave w = $path                      // Using string variable
```

Things get more complicated when you use a liberal name rather than a standard name. A standard name starts with a letter and includes letters, digits and the underscore character. A liberal name includes other characters such as spaces or punctuation.

In general, you must quote liberal names using a single quote so that Igor can determine where the name starts and where it ends. For example:

```
Wave w = root:'My Data Folder':'My Wave'  // Using literal path
String path = "root:'My Data Folder':'My Wave'"
Wave w = $path                            // Using string variable
```

However, there is an exception to the quoting requirement. The rule is:

> You must quote a literal liberal name and you must quote a liberal path stored in a string variable but you must not quote a simple literal liberal name stored in a string variable.

The following functions illustrate this rule:

```
// Literal liberal name must be quoted
Function DemoLiteralLiberalNames()
   NewDataFolder/O root:'My Data Folder'

   Make/O root:'My Data Folder':'My Wave' // Literal name must be quoted
```

```
   SetDataFolder root:'My Data Folder'    // Literal name must be quoted

   Wave w = 'My Wave'                     // Literal name must be quoted
   w = 123

   SetDataFolder root:
End

// String liberal PATH must be quoted
Function DemoStringLiberalPaths()
   String path = "root:'My Data Folder'"
   NewDataFolder/O $path

   path = "root:'My Data Folder':'My Wave'"  // String path must be quoted
   Make/O $path

   Wave w = $path
   w = 123

   SetDataFolder root:
End

// String liberal NAME must NOT be quoted
Function DemoStringLiberalNames()
   SetDataFolder root:

   String dfName = "My Data Folder"       // String name must NOT be quoted
   NewDataFolder/O $dfName

   String wName = "My Wave"               // String name must NOT be quoted
   Make/O root:$(dfName):$wName

   Wave w = root:$(dfName):$wName         // String name must NOT be quoted
   w = 123

   SetDataFolder root:
End
```

The last example illustrates another subtlety. This command would generate an error at compile time:

```
   Make/O root:$dfName:$wName       // ERROR
```

because Igor would intepret it as:

```
   Make/O root:$(dfName:$wName)     // ERROR
```

To avoid this, you must use parentheses like this:

```
   Make/O root:$(dfName):$wName     // OK
```

Runtime Lookup Example

In this example, a function named Routine calls another function named Subroutine and needs to access a number of result values created by Subroutine. To make it easy to clean up the temporary result globals, Subroutine creates them in a new data folder. Routine uses the results created by Subroutine and then deletes the temporary data folder.

```
Function Subroutine(w)
   WAVE w

   NewDataFolder/O/S SubroutineResults    // Results go here
```

```
   WaveStats/Q w           // WaveStats creates local variables
   Variable/G gAvg= V_avg  // Return the V_avg result in global gAvg
   Variable/G gMin= V_min
   String/G gWName= NameOfWave(w)

   SetDataFolder ::        // Back to original data folder
End

Function Routine()
   Make aWave= {1,2,3,4}
   Subroutine(aWave)
   NVAR theAvg= :SubroutineResults:gAvg   // theAvg is local name
   NVAR theMin= :SubroutineResults:gMin
   SVAR theName= :SubroutineResults:gWName
   Print theAvg,theMin,theName
   KillDataFolder SubroutineResults    // We are done with results
End
```

Note that the NVAR statement must appear *after* the procedure (Subroutine in this case) that creates the global variable. This is because NVAR has both a compile-time and a runtime behavior. At compile time, it creates a name that Igor can compile (theAvg in this case). At runtime, it actually looks up and creates a link to the global (variable gAvg stored in data folder SubroutineResults in this case).

Often a Function will need to access quite a large number of global variables stored in a data folder. In such cases, you can write more compact code using the ability of NVAR, SVAR or WAVE to access multiple objects in the current data folder as illustrated here:

```
Function Routine2()
   Make/O aWave= {1,2,3,4}
   Subroutine(aWave)

   String dfSav=GetDataFolder(1)
   SetDataFolder :SubroutineResults
   NVAR gAvg,gMin             // Access two variables via one NVAR
   SVAR gWName
   SetDataFolder dfSav

   Print gAvg,gMin,gWName
   KillDataFolder SubroutineResults    // We are done with results
End
```

Automatic Creation of NVAR and SVAR References

The Igor compiler sometimes automatically creates NVAR and SVAR references. For example:

```
Function Example1()
   Variable/G gVar1
   gVar1= 1

   String/G gStr1
   gStr1= "hello"
End
```

In this example we did not use NVAR or SVAR references and yet we were still able to compile assignment statements referring to global variables which will not exist until runtime. This is a feature of `Variable/G` and `String/G` that automatically create local references for simple object names.

Simple object names are names which are known at compile time for objects which will be created in the current data folder at runtime. `Variable/G` and `String/G` do not create references if you use $<name>, a partial data folder path or a full data folder path to specify the object.

Wave References

A wave reference is a lightweight object used in user-defined functions to specify the wave of interest in assignment statements and other commands. You can think of a wave reference as an identification number that Igor uses to identify a particular wave.

Wave reference variables hold wave references. They can be created as local variables, passed as parameters and returned as function results.

Here is a simple example:

```
Function Test(wIn)
   Wave wIn          // Reference to the input wave received as parameter

   String newName = NameOfWave(wIn) + "_out" // Compute output wave name

   Duplicate/O wIn, $newName                 // Create output wave

   Wave wOut = $newName       // Create wave reference for output wave
   wOut += 1                  // Use wave reference in assignment statement
End
```

This function might be called from the command line or from another function like this:

```
Make/O/N=5 wave0 = p
Test(wave0)                   // Pass wave reference to Test function
```

A Wave statement has both a compile-time and a runtime effect.

At compile time, it tells Igor what type of object the declared name references. In the example above, it tells Igor that wOut references a wave as opposed to a numeric variable, a string variable, a window or some other type of object. The Igor compiler allows wOut to be used in a waveform assignment statement (wOut += 1) because it knows that wOut references a wave.

The compiler also needs to know if the wave is real, complex or text. Use Wave/C to create a complex wave reference and Wave/T to create a text wave reference. Wave by itself creates a real wave reference.

At runtime the Wave statement stores a reference to a specific wave in the wave reference variable (wOut in this example). The referenced wave must already exist when the wave statement executes. Otherwise Igor will store a NULL reference in the wave reference variable and you will get an error when you attempt to use it. We put the "`Wave wOut = $newName`" statement *after* the Duplicate operation to insure that the wave exists when the Wave statement is executed. Putting the Wave statement before the command that creates the wave is a common error.

Automatic Creation of WAVE References

The Igor compiler sometimes automatically creates WAVE references. For example:

```
Function Example1()
   Make wave1
   wave1= x^2
End
```

In this example we did not use a WAVE reference and yet we were still able to compile an assignment statement referring to a wave which will not exist until runtime. This is a feature of the **Make** operation (see page V-366) which automatically creates local references for simple object names. The **Duplicate** operation (see page V-133) and many other operations that create output waves also automatically create local wave references for simple object names.

Simple object names are names which are known at compile time for objects which will be created in the current data folder at runtime. Make and Duplicate do not create references if you use $<name>, a partial

data folder path or a full data folder path to specify the object. However, as of Igor Pro 6.1, you can append /WAVE=<name> after a $ or path specification to explicitly create a WAVE reference.

In the case of Make and Duplicate with simple object names, the type of the automatically created wave reference (real, complex or text) is determined by flags. Make/C and Duplicate/C create complex wave references. Make/T and Duplicate/T create text wave references. Make and Duplicate without type flags create real wave references. See **WAVE Reference Types** on page IV-58 and **WAVE Reference Type Flags** on page IV-58 for a complete list of type flags and further details.

Most built-in operations that create output waves (often called "destination" waves) also automatically create wave references. For example, if you write:

```
DWT srcWave, destWave
```

it is as if you wrote:

```
DWT srcWave, destWave
WAVE destWave
```

After the discrete wavelet transform executes, you can reference `destWave` without an explicit wave reference.

Standalone WAVE Reference Statements

In cases where Igor does not automatically create a wave reference, because the output wave is not specified using a simple object name, you need to explicitly create a wave reference if you want to access the wave in an assignment statement.

You can create an explicit standalone wave reference using a statement following the command that created the output wave. In this example, the name of the output wave is specified as a parameter and therefore we can not use a simple object name when calling Make:

```
Function Example2(nameForOutputWave)
   String nameForOutputWave   // String contains the name of the wave to make

   Make $nameForOutputWave          // Make a wave
   Wave w = $nameForOutputWave      // Make a wave reference
   w= x^2
End
```

If you make a text wave or a complex wave, you need to tell the Igor compiler about that by using Wave/T or Wave/C. The compiler needs to know the type of the wave in order to properly compile the assignment statement.

Inline WAVE Reference Statements

In Igor Pro 6.1 or later, you can create a wave reference variable using /WAVE=<name> in the command that creates the output wave. For example:

```
Function Example3(nameForOutputWave)
   String nameForOutputWave

   Make $nameForOutputWave/Wave=w   // Make a wave and a wave reference
   w= x^2
End
```

Here /Wave=w is an inline wave reference statement. It does the same thing as the standalone wave reference in the preceding section.

Here are some more examples of inline wave declarations:

```
Function Example4()
   String name = "wave1"
   Duplicate/O wave0, $name/WAVE=wave1
```

```
   Differentiate wave0 /D=$name/WAVE=wave1
End
```

When using an inline wave reference statement, you do not need to, and in fact can not, specify the type of the wave using Wave/T or Wave/C. Just use Wave by itself regardless of the type of the output wave. The Igor compiler automatically creates the right kind of wave reference. For example:

```
Function Example5()
   Make real1, $"real2"/WAVE=r2     // real1, real2 and r2 are real
   Make/C cplx1, $"cplx2"/WAVE=c2   // cplx1, cplx2 and c2 are complex
   Make/T text1, $"text2"/WAVE=t2   // text1, text2 and t2 are text
End
```

Inline wave reference statements are accepted by those operations which automatically create a wave reference for a simple object name.

Inline wave references are not allowed after a simple object name.

Inline wave references are allowed on the command line but do nothing.

WAVE Reference Types

When WAVE references are created at compile time, they are created with a specific numeric type or are defined as text. The compiler then uses this type when creating expressions based on the WAVE reference or when trying to match two instances of the same name. For example:

```
Make rWave

Make/C cWave

Make/T tWave
```

creates single precision real, single precision complex, and text WAVE reference variables. These types then define what kind of right-hand side expression to compile:

```
rWave= expression       // will be real

cWave= expression       // will be complex

tWave= expression       // will be text
```

At the present time, these are the only three types of expressions that the compiler creates and numeric expressions are always evaluated in double precision. However, in the future, the compiler might be extended to create integer or single precision code. As a result of these considerations, the compiler is sometimes quite picky about the exact congruence between two declarations of WAVE reference variables of the same name (which create just a single instance). For example:

```
WAVE aWave
if( !WaveExists(aWave) )
   Make/D aWave
endif
```

will give a compile error complaining about inconsistent type for a WAVE reference. This is because the default type for the WAVE reference is single precision real. In this case, you will need to use the /D flag like so:

```
WAVE/D aWave
```

WAVE Reference Type Flags

The **WAVE** reference (see page V-722) along with certain operations such as Duplicate can accept the following flags identifying the type of WAVE reference:

/B	8-bit signed integer destination waves, unsigned with /U.
/C	complex destination waves.

/D	double precision destination waves.
/I	32-bit signed integer destination waves, unsigned with /U.
/S	single precision destination waves.
/T	text destination waves.
/U	unsigned destination waves.
/W	16-bit signed integer destination waves, unsigned with /U.
/DF	Wave holds data folder references. For advanced programmers only running Igor Pro 6.1 or later.
/WAVE	Wave holds wave references. For advanced programmers only running Igor Pro 6.1 or later.

These are the same flags used by the **Make** operation (see page V-366) except in this case they do not affect the actual wave and are used only specify what kind of wave is expected at runtime. This information is used if, later in the function, you create a wave assignment statement using a duplicated wave as the destination:

```
Function DupIt(wv)
   WAVE/C wv                  // complex wave

   Duplicate/O/C wv,dupWv     // dupWv is complex
   dupWv[0]=cmplx(5.0,1.0)    // no error, because dupWv known complex
   . . .
End
```

If Duplicate did not have the /C flag, you would get a "function not available for this number type" message when compiling the assignment of `dupWv` to the result of the `cmplx` function.

Problems with Automatic Creation of WAVE References

Operations that change a wave's type or which can create output waves of more than one type, such as **FFT**, **IFFT** and **WignerTransform** present special issues.

In some cases, the wave reference automatically created by an operation might be of the wrong type. For example, the FFT operation automatically creates a complex wave reference for the destination wave, so if you write:

```
FFT/DEST=destWave srcWave
```

it is as if you wrote:

```
FFT/DEST=destWave srcWave
WAVE/C destWave
```

However, if a real wave reference for the same name already exists, FFT/DEST will not create a new wave reference. For example:

```
Wave destWave                 // Real wave reference
. . .
FFT /DEST=destWave srcWave    // FFT does not create wave reference
                              // because it already exists.
```

In this case, you would need to create a complex wave reference using a different name, like this:

```
Wave/C cDestWave = destWave
```

The output of the FFT operation can sometimes be real, not complex. For example:

```
FFT/DEST=destWave/OUT=2 srcWave
```

The /OUT=2 flag creates a real destination wave. Thus the complex wave reference automatically created by the FFT operation is wrong and can not be used to subsequently access the destination wave. In this case, you must explicitly create a real wave reference, like this:

```
FFT/DEST=destWave/OUT=2 srcWave
WAVE realDestWave = destWave
```

Note that you can not write:

```
FFT/DEST=destWave/OUT=2 srcWave
WAVE destWave
```

because the FFT operation has already created a complex wave reference named `destWave`, so the compiler will generate an error. You must use a different name for the real wave reference.

The **IFFT** has a similar problem but in reverse. IFFT automatically creates a real wave reference for the destination wave. In some cases, the actual destination wave will be complex and you will need to create an explicit wave reference in order to access it.

WAVE Reference Is Not Needed to Pass a Wave Parameter

You don't need to use a WAVE reference when passing a literal wave name as a parameter to an operation or function. For example:

```
Function Test()
   Display jack
   Display root:jack
   Variable tmp = mean(jack,0,100)
End
```

In these examples, Igor knows that the parameters of the Display operation and the first parameter of the mean function are waves and therefore does not need the additional information provided by the WAVE reference.

Wave Reference Function Results

In Igor Pro 6.1 or later, advanced programmers can create functions that return wave references using Function/WAVE:

```
Function/WAVE Test(wIn) // /WAVE flag says function returns wave reference
   Wave wIn    // Reference to the input wave received as parameter

   String newName = NameOfWave(wIn) + "_out" // Compute output wave name

   Duplicate/O wIn, $newName                 // Create output wave

   Wave wOut = $newName       // Create wave reference for output wave
   wOut += 1                  // Use wave reference in assignment statement

   return wOut                // Return wave reference
End
```

This function might be called from another function like this:

```
Make/O/N=5 wave0 = p
Wave wOut = Test(wave0)
Display wave0, wOut
```

Wave Reference Waves

In Igor Pro 6.1 or later, you can create waves that contain wave references using the Make /WAVE flag. You can use a wave reference wave as a list of waves for further processing and in multithreaded wave assignment using the **MultiThread** keyword.

Wave reference waves are recommended for advanced programmers only.

Note: Wave reference waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only.

Here is an example:

```
Make/O wave0, wave1, wave2              // Make some waves
Make/O/WAVE wr                          // Make a wave reference wave
wr[0]=wave0; wr[1]=wave1; wr[2]=wave2   // Assign values
```

The wave reference wave wr could now be used, for example, to pass a list of waves to a function that performs display or analysis operations.

Make/WAVE without any assignment creates a wave containing null wave references. Similarly, inserting points or redimensioning to a larger size initializes the new points to null. Deleting points or redimensioning to a smaller size deletes any free waves if the deleted points contained the only reference to them.

To determine if a given wave is a type that stores wave references, use the **WaveType** function with the optional selector = 1.

In the next example, a subroutine supplies a list of references to waves to be graphed by the main routine. A wave reference wave is used to store the list of wave references.

```
Function MainRoutine()
   Make/O/WAVE/N=5 wr      // Will contain references to other waves
   wr= Subroutine(p)       // Fill w with references

   WAVE w= wr[0]           // Get reference to first wave
   Display w               // and display in a graph

   Variable i
   for(i=1;i<5;i+=1)
      WAVE w= wr[i]        // Get reference to next wave
      AppendToGraph w      // and append to graph
   endfor
End

Function/WAVE Subroutine(i)
   Variable i

   String name = "wave"+num2str(i)

   // Create a wave with a computed name and also a wave reference to it
   Make/O $name/WAVE=w = sin(x/(8+i))

   return w       // Return the wave reference to the calling routine
End
```

For an example using a wave reference wave for multiprocessing, see **Wave Reference MultiThread Example** on page IV-286.

Data Folder References

The data folder reference is a lightweight object that refers to a data folder, analogous to the wave reference which refers to a wave. You can think of a data folder reference as an identification number that Igor uses to identify a particular data folder.

Data folder references require Igor Pro 6.1 or later.

Data folder reference variables (DFREFs) hold data folder references. They can be created as local variables, passed as parameters and returned as function results.

The most common use for a data folder reference is to save and restore the current data folder during the execution of a function:

```
Function Test()
   DFREF saveDFR = GetDataFolderDFR()  // Get reference to current data folder

   NewDataFolder/O/S MyNewDataFolder   // Create a new data folder
   . . .                               // Do some work in it

   SetDataFolder saveDFR               // Restore current data folder
End
```

Data folder references can be used in commands where Igor accepts a data folder path. For example, this function shows three equivalent methods of accessing waves in a specific data folder:

```
Function Test()
   // Method 1: Using paths
   Display root:Packages:'My Package':yWave vs root:Packages:'My Package':xWave

   // Method 2: Using the current data folder
   String dfSave = GetDataFolder(1) // Save the current data folder
   SetDataFolder root:Packages:'My Package'
   Display yWave vs xWave
   SetDataFolder dfSave             // Restore current data folder

   // Method 3: Using data folder references
   DFREF dfr = root:Packages:'My Package'
   Display dfr:yWave vs dfr:xWave
End
```

Using data folder references instead of data folder paths can streamline programs that make heavy use of data folders.

Using Data Folder References

In an advanced application, the programmer often defines a set of named data objects (waves, numeric variables and string variables) that the application acts on. These objects exist in a data folder. If there is just one instance of the set, it is possible to hard-code data folder paths to the objects. Often, however, there will be a multiplicity of such sets, for example, one set per graph or one set per channel in a data acquisition application. In such applications, procedures must be written to act on the set of data objects in a data folder specified at runtime.

One way to specify a data folder at runtime is to create a path to the data folder in a string variable. While this works, you wind up with code that does a lot of concatenation of data folder paths and data object names. Using data folder references, such code can be streamlined.

You create a data folder reference variable with a DFREF statement. For example, assume your application defines a set of data with a wave named wave0, a numeric variable named num0 and a string named str0 and that we have one data folder containing such a set for each graph. You can access your objects like this:

```
Function DoSomething(graphName)
   String graphName
   DFREF dfr = root:Packages:MyApplication:$graphName
   WAVE w0 = dfr:wave0
   NVAR n0 = dfr:num0
   SVAR s0 = dfr:str0
   . . .
End
```

Igor accepts a data folder reference in any command in which a data folder path would be accepted. For example:

```
Function Test()
   Display root:MyDataFolder:wave0  // OK

   DFREF dfr = root:MyDataFolder
   Display dfr:wave0                // OK

   String path = "root:MyDataFolder:wave0"
   Display $path                    // OK. $ converts string to path.

   path = "root:MyDataFolder"
   DFREF dfr = $path                // OK. $ converts string to path.
   Display dfr:wave0                // OK

   String currentDFPath
   currentDFPath = GetDataFolder(1) // OK
   DFREF dfr = GetDataFolder(1)     // ERROR: GetDataFolder returns a string
                                    // not a path.
End
```

The /SDFR Flag

In Igor Pro 6.20 or later you can also use the /SDFR (source data folder reference) flag in a WAVE, NVAR or SVAR statement. The utility of /SDFR is illustrated by this example which shows three different ways to reference multiple waves in the same data folder:

```
Function Test()
   // Assume a data folder exists at root:Run1

   // Use explicit paths
   Wave wave0=root:Run1:wave0, wave1=root:Run1:wave1, wave2=root:Run1:wave2

   // Use a data folder reference
   DFREF dfr = root:Run1
   Wave wave0=dfr:wave0, wave1=dfr:wave1, wave2=dfr:wave2

   // Use the /SDFR flag
   DFREF dfr = root:Run1
   Wave/SDFR=dfr wave0, wave1, wave2
End
```

The DFREF Type

In Functions, you can define data folder reference variables using the DFREF declaration:

```
DFREF localname [= <DataFolderRef or path>] [<more defs]
```

You can then use the data folder reference in those places where you can use a data folder path. For example:

```
DFREF dfr= root:df1
Display dfr:wave1             // Equivalent to Display root:df1:wave1
```

The syntax is limited to a single name after the data folder reference, so this is not legal:

```
Display dfr:subfolder:wave1   // Illegal
```

You can use DFREF to define input parameters for user-defined functions. For example:

```
Function Test(df)
   DFREF df
   Display df:wave1
End
```

You can also use DFREF to define fields in structures. However, you can not directly use a DFREF structure field in those places where Igor is expecting a path and object name. So, instead of:

```
Display s.dfr:wave1              // Illegal
```

you would need to write:

```
DFREF dftmp= s.dfr
Display dftmp:wave1              // OK
```

You can use a DFREF structure field where just a path is expected. For example:

```
SetDataFolder s.dfr              // OK
```

Built-in DFREF Functions

Some built-in functions take string data folder paths as parameters or return them as results. Those functions can not take or return data folder references. Here are equivalent DFREF versions that take or return data folder references:

```
GetDataFolderDFR()

GetIndexedObjNameDFR(dfr, type, index)

GetWavesDataFolderDFR(wave)

CountObjectsDFR(dfr, type)
```

These additional data folder reference functions are available:

```
DataFolderRefStatus(dfr)

NewFreeDataFolder()

DataFolderRefsEqual(dfr1, dfr2)
```

Just as operations that take a data folder path accept a data folder reference, these DFREF functions can also accept a data folder path:

```
Function Test()
   DFREF dfr = root:MyDataFolder
   Print CountObjectsDFR(dfr,1)                  // OK
   Print CountObjectsDFR(root:MyDataFolder,1)    // OK
End
```

Checking Data Folder Reference Validity

The **DataFolderRefStatus** function returns zero if the data folder reference is invalid. You should use it to test any DFREF variables that might not be valid, for example, when you assign a value to a data folder reference and you are not sure that the referenced data folder exists:

```
Function Test()
   DFREF dfr = root:MyDataFolder    // MyDataFolder may or may not exist
   if (DataFolderRefStatus(dfr) != 0)
      . . .
   endif
End
```

For historical reasons, an invalid DFREF variable will often act like root.

Data Folder Reference Function Results

A user-defined function can return a data folder reference. This might be used for a subroutine that returns a set of new objects to the calling routine. The set can be returned in a new data folder and the subroutine can return a reference it.

For example:

```
Function/DF Subroutine(newDFName)
   String newDFName
   NewDataFolder/O $newDFName
   DFREF dfr = $newDFName
   Make/O dfr:wave0, dfr:wave1
   return dfr
End

Function/DF MainRoutine()
   DFREF dfr = Subroutine("MyDataFolder")
   Display dfr:wave0, dfr:wave1
End
```

Data Folder Reference Waves

In Igor Pro 6.1 or later, you can create waves that contain data folder references using the **Make** /DF flag. You can use a data folder reference wave as a list of data folders for further processing and in multithreaded wave assignment using the MultiThread keyword.

Data folder reference waves are recommended for advanced programmers only.

Note: Data folder reference waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only.

Make/DF without any assignment creates a wave containing null data folder references. Similarly, inserting points or redimensioning to a larger size initializes the new points to null. Deleting points or redimensioning to a smaller size deletes any free data folders if the wave contained the only reference to them.

To determine if a given wave is a type that stores data folder references, use the **WaveType** function with the optional selector = 1.

Although programmers may find multiple uses of data folder reference waves, the main impetus for their development was to make it easier to improve calculation performance by multithreading on multi-core machines.

For an example using a data folder reference wave for multiprocessing, see **Data Folder Reference Multi-Thread Example** on page IV-285.

Accessing Waves in Functions

To access a wave, we need to create, one way or another, a wave reference. The section **Accessing Global Variables and Waves** on page IV-50 explained how to access a wave using a WAVE reference. This section introduces several additional techniques. Other useful details may be found in **Returning Created Waves from User Functions** on page III-142.

We can create the wave reference by:

- Declaring a wave parameter
- Using $<string expression>
- Using a literal wave name
- Using a wave reference function

Each of these techniques is illustrated in the following sections.

Each example shows a function and commands that call the function. The function itself illustrates how to deal with the wave within the function. The commands show how to pass enough information to the function so that it can access the wave. Other examples can be found in **Writing Functions that Process Waves** on page III-143.

Wave Reference Passed as Parameter

This is the simplest method. The function might be called from the command line or from another function.

```
Function Test(w)
   WAVE w                  // Wave reference passed as a parameter

   w += 1                  // Use in assignment statement
   Print mean(w,-INF,INF)  // Pass as function parameter
   WaveStats w             // Pass as operation parameter
   AnotherFunction(w)      // Pass as user function parameter
End

Make/O/N=5 wave0 = p
Test(wave0)
Test($"wave0")
String wName = "wave0"; Test($wName)
```

In the first call to Test, the wave reference is a literal wave name. In the second call, we create the wave reference using $<literal string>. In the third call, we create the wave reference using $<string variable>. $<literal string> and $<string variable> are specific cases of the general case $<string expression>.

If the function expected to receive a reference to a text wave, we would declare the parameter using:

```
   WAVE/T w
```

If the function expected to be receive a reference to a complex wave, we would declare the parameter using:

```
   WAVE/C w
```

If you need to return a large number of values to the calling routine, it is sometimes convenient to use a parameter wave as an output mechanism. The following example illustrates this technique:

```
Function MyWaveStats(inputWave, outputWave)
   WAVE inputWave
   WAVE outputWave

   WaveStats/Q inputWave

   outputWave[0] = V_npnts
   outputWave[1] = V_avg
   outputWave[2] = V_sdev
End

Function Test()
   Make/O testwave= gnoise(1)

   Make/O/N=20 tempResultWave
   MyWaveStats(testwave, tempResultWave)
   Variable npnts = tempResultWave[0]
   Variable avg = tempResultWave[1]
   Variable sdev = tempResultWave[2]
   KillWaves tempResultWave

   Printf "Points: %g; Avg: %g; SDev: %g\r", npnts, avg, sdev
End
```

Wave Accessed Via String Passed as Parameter

This technique is of most use when the wave might not exist when the function is called. It is appropriate for functions that create waves.

```
Function Test(wName)
   String wName            // String containing a name for wave

   Make/O/N=5 $wName
   WAVE w = $wName         // Create a wave reference
   Print NameOfWave(w)
```

```
End

Test("wave0")
```

This example will create wave0 if it does not yet exist or overwrite it if it does exist. If we knew that the wave had to already exist, we could and should use the wave parameter technique shown in the preceding section. In this case, since the wave may not yet exist, we can not use a wave parameter.

Notice that we create a wave reference immediately after making the wave. Once we do this, we can use the wave reference in all of the ways shown in the preceding section. We can not create the wave reference before making the wave because a wave reference must refer to an existing wave.

The following command demonstrates that $wName and the wave reference w can refer to a wave that is not in the current data folder.

```
NewDataFolder root:Folder1; Test("root:Folder1:wave0")
```

Wave Accessed Via String Calculated in Function

This technique is used when creating multiple waves in a function or when algorithmically selecting a wave or a set of waves to be processed.

```
Function Test(baseName, startIndex, endIndex)
   String baseName
   Variable startIndex, endIndex

   Variable index = startIndex
   do
      WAVE w = $(baseName + num2istr(index))
      WaveStats/Q w
      Printf "Wave: %s; average: %g\r", NameOfWave(w), V_avg
      index += 1
   while (index <= endIndex)
End

Make/O/N=5 wave0=gnoise(1), wave1=gnoise(1), wave2=gnoise(1)
Test("wave", 0, 2)
```

We need to use this method because we want the function to operate on any number of waves. If the function were to operate on a small, fixed number of waves, we could use the wave parameter method.

As in the preceding section, we create a wave reference using $<string expression>.

Wave Accessed Via Literal Wave Name

In data acquisition or analysis projects, you often need to write procedures that deal with runs of identically-structured data. Each run is stored in its own data folder and contains waves with the same names. In this kind of situation, you can write a set of functions that use literal wave names specific for your data structure.

```
Function CreateRatio()
   WAVE dataA, dataB
   Duplicate dataA, ratioAB
   WAVE ratioAB
   ratioAB = dataA / dataB
End

Make/O/N=5 dataA = 1 + p, dataB = 2 + p
CreateRatio()
```

The CreateRatio function assumes the structure and naming of the data. The function is hard-wired to this naming scheme and assumes that the current data folder contains the appropriate data.

Wave Accessed Via Wave Reference Function

A wave reference function is a built-in Igor function that returns a reference to a wave. Wave reference functions are typically used on the right-hand side of a WAVE statement. For example:

```
WAVE w = WaveRefIndexed("",i,4)
```

A common use for a wave reference function is to get access to waves displayed in a graph, using the TraceNameToWaveRef function. Here is an example.

```
Function PrintAverageOfDisplayedWaves()
   String list, traceName

   list = TraceNameList("",";",1)   // List of traces in top graph
   Variable index = 0
   do
      traceName = StringFromList(index, list)   // Next trace name
      if (strlen(traceName) == 0)
         break                                  // No more traces
      endif
      WAVE w = TraceNameToWaveRef("", traceName)// Get wave ref
      WaveStats/Q w
      Printf "Wave: %s; average: %g\r", NameOfWave(w), V_avg
      index += 1
   while (1)               // loop till break above
End

Make/O/N=5 wave0=gnoise(1), wave1=gnoise(1), wave2=gnoise(1)
Display wave0, wave1, wave2
PrintAverageOfDisplayedWaves()
```

There are other wave reference functions (see **Wave Reference Functions** on page IV-173), but WaveRefIndexed and TraceNameToWaveRef are the most used.

Destination Wave Parameters

Many operations create waves. Examples are Make, Duplicate and Differentiate. Such operations take "destination wave" parameters. A destination wave parameter can be:

A simple name

```
Differentiate fred /D=jack
```

A path

```
Differentiate fred /D=root:FolderA:jack
```

$ followed by a string expression

```
String str = "root:FolderA:jack"
Differentiate fred /D=$str
```

A simple wave reference

```
Wave/Z jack
Differentiate fred /D=jack
```

Other wave references

```
Wave/Z w = jack
Differentiate fred /D=w

Wave/Z w = root:FolderA:jack
Differentiate fred /D=w

Wave/Z jack = root:FolderA:jack
Differentiate fred /D=jack

STRUCT MyStruct s// Contains wave ref field w
Differentiate fred /D=s.w
```

The wave reference works only in a user-defined function. The other techniques work in functions, in macros and from the command line.

The first and fourth cases are actually the same because, if you use a simple name, the Igor compiler automatically creates a wave reference as if you had used a simple wave reference as explained under **Automatic Creation of WAVE References** on page IV-56.

Using the first four techniques, the destination wave may or may not already exist. It will be created if it does not exist and overwritten if it does exist.

In the last technique, the name of the wave reference is different from the name of the destination wave or the wave reference points to a data folder other than the current data folder or both. This technique works properly only if the referenced wave already exists. Otherwise the destination wave is a wave with the name of the wave reference itself (w in the first two examples, jack in the last) in the current data folder. This situation is further explained below under **Destination Wave Reference Issues** on page IV-70.

Wave Reference as Destination Wave

Here are the rules for wave references when used as destination waves:

1. If a simple name (not a wave reference) is passed as the destination wave parameter, the destination wave is a wave of that name in the current data folder whether it exists or not.
2. If a path or $ followed by a string containing a path is passed as the destination wave parameter, the destination wave is specified by the path whether the specified wave exists or not.
3. If a wave reference is passed as the destination wave parameter, the destination wave is the referenced wave if it exists. See **Destination Wave Reference Issues** on page IV-70 for what happens if it does not exist.

Exceptions To Destination Wave Rules

The Make operation is an exception in regard to wave references. The following statements make a wave named w in the current data folder whether root:FolderA:jack exists or not:

```
Wave/Z w = root:FolderA:jack
Make/O w
```

Prior to Igor Pro 6.20, many operations behaved like Make in this regard. In Igor Pro 6.20 and later, most operations behave like Differentiate.

Updating of Destination Wave References

When a simple name is provided in a user-defined function, Igor automatically creates a wave reference variable of that name at compile time if one does not already exist. This is an "implicit" wave reference.

When a wave reference variable exists, whether implicit or explicit, during the execution of the command, the operation stores a reference to the destination wave in that wave reference variable. You can use the wave reference to access the destination wave in subsequent commands.

Similarly, when the destination is specified using a wave reference field in a structure, the operation updates the field to refer to the destination wave.

Inline Wave References With Destination Waves

When the destination wave is specified using a path or a string containing a path, you can use an inline wave reference to create a reference to the destination wave. For example:

```
String str = "root:FolderA:jack"
Differentiate $str /D=$dest/WAVE=wDest
Display wDest
```

Here the Igor compiler creates a wave reference named wDest. The Differentiate operation stores a reference to the destination wave (root:FolderA:jack in this case) in wDest which can then be used to access the destination wave in subsequent commands.

Inline wave references do not determine which wave is the destination wave but merely provide a wave reference pointing to the destination wave when the command finishes.

Destination Wave Reference Issues

You will get unexpected behavior when a wave reference variable refers to a wave with a different name or in a different data folder and the referenced wave does not exist. For example, if the referenced wave does not exist:

```
Wave/Z w = jack
Differentiate fred /D=w    // Creates a wave named w in current data folder

Wave/Z w = root:FolderA:jack
Differentiate fred /D=w    // Creates a wave named w in current data folder

Wave/Z jack = root:FolderA:jack
Differentiate fred /D=jack // Creates a wave named jack in current data folder

STRUCT MyStruct s          // Contains wave ref field w
Differentiate fred /D=s.w  // Creates a wave named w in current data folder
```

In a situation like this, you should add a test using WaveExists to verify that the destination wave is valid and throw an error if not or otherwise handle the situation. For example:

```
Wave/Z w = root:FolderA:jack
if (!WaveExists(w))
   Abort "Destination wave does not exist"
endif
Differentiate fred /D=w
```

As noted above, when you use a simple name as a destination wave, the Igor compiler automatically creates a wave reference. If the automatically-created wave reference conflicts with a pre-existing wave reference, the compiler will generate an error. For example, this function generates an "inconsistent type for wave reference error":

```
Function InconsistentTypeError()
   Wave/C w                   // Explicit complex wave reference
   Differentiate fred /D=w    // Implicit real wave reference
End
```

Another consideration involves loops. Suppose in a loop you have code like this:

```
   SetDataFolder <something depending on loop index>
   Duplicate/O srcWave, jack
```

You may think you are creating a wave named jack in each data folder but, because the contents of the automatically-created wave refrence variable jack is non-null after the first iteration, you will simply be overwriting the same wave over and over. To fix this, use

```
   Duplicate/O srcWave,$"jack"/WAVE=jack
```

This will create a wave named jack in the current data folder and store a reference to it in a wave reference variable also named jack.

Changes in Destination Wave Behavior

Igor's handling of destination wave references was improved for Igor Pro 6.20. Previously some operations treated wave references as simple names, did not set the wave reference to refer to the destination wave on output, and exhibited other non-standard behavior.

Trace Name Parameters

The ModifyGraph operation takes trace name parameters. A trace name is not the same as a wave. An example may clarify this subtle point:

```
Function Test()
   Wave w = root:FolderA:wave0
   Display w
   ModifyGraph rgb(w) = (65535,0,0)          // WRONG
End
```

This is wrong because ModifyGraph is looking for the name of a trace in a graph and w is not the name of a trace in a graph. The name of the trace in this case is wave0. The function should be written like this:

```
Function Test()
   Wave w = root:FolderA:wave0
   Display w
   ModifyGraph rgb(wave0) = (65535,0,0)      // CORRECT
End
```

In the next example, the wave is passed to the function as a parameter so the name of the trace is not so obvious:

```
Function Test(w)
   Wave w
   Display w
   ModifyGraph rgb(w) = (65535,0,0)          // WRONG
End
```

This is wrong for the same reason as the first example: w is not the name of the trace. The function should be written like this:

```
Function Test(w)
   Wave w
   Display w

   String name = NameOfWave(w)
   ModifyGraph rgb($name) = (65535,0,0)      // CORRECT
End
```

User-defined Trace Names

As of Igor Pro 6.20, you can provide user-defined names for traces using /TN=<name> with **Display** and **AppendToGraph**. For example:

```
Make/O jack=sin(x/8)
NewDataFolder/O foo; Make/O :foo:jack=sin(x/9)
NewDataFolder/O bar; Make/O :bar:jack=sin(x/10)
Display jack/TN='jack in root', :foo:jack/TN='jack in foo'
AppendToGraph :bar:jack/TN='jack in bar'
ModifyGraph mode('jack in bar')=7,hbFill('jack in bar')=6
ModifyGraph rgb('jack in bar')=(0,0,65535)
```

Warning: Using this feature will make your experiment hard to load into versions prior to 6.20. Also, any code that assumes the trace name contains the wave name will fail.

Free Waves

Free waves are waves that are not part of any data folder hierarchy. Their principal use is in multithreaded wave assignment using the MultiThread keyword in a function. They can also be used for temporary storage within functions.

Free waves are recommended for advanced programmers only.

Free waves require Igor Pro 6.1 or later.

Note: Free waves are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only.

You create free waves using the **NewFreeWave** function and the **Make**/FREE and **Duplicate**/FREE operations.

Here is an example:

```
Function ReverseWave(w)
   Wave w

   Variable lastPoint = numpnts(w) - 1
   if (lastPoint > 0)
      // This creates a free wave named wTemp.
      // It also creates an automatic wave reference named wTemp
      // which refers to the free wave.
      Duplicate /FREE w, wTemp

      w = wTemp[lastPoint-p]
   endif
End
```

In this example, wTemp is a free wave. As such, it is not contained in any data folder and therefore can not conflict with any other wave.

As explained below under **Free Wave Lifetime** on page IV-73, a free wave is automatically deleted when there are no more references to it. In this example that happens when the function ends.

You can access a free wave only using the wave reference returned by NewFreeWave, Make/FREE or Duplicate/FREE.

Free waves can not be used in situations where global persistence is required such as in graphs, tables and controls. In other words, you should use free waves for computation purposes only.

For a discussion of multithreaded assignment statements, see **Automatic Parallel Processing with MultiThread** on page IV-283. For an example using free waves, see **Wave Reference MultiThread Example** on page IV-286.

Free Wave Created When Free Data Folder Is Deleted

In addition to the explicit creation of free waves, a wave that is created in a free data folder becomes free if the host data folder is deleted but a reference to the wave still exists. For example:

```
Function/WAVE Test()
   DFREF dfSav= GetDataFolderDFR()

   SetDataFolder NewFreeDataFolder()
   Make jack={1,2,3}// jack is not a free wave at this point.
   // This also creates an automatic wave reference named jack.

   SetDataFolder dfSav
   // The free data folder is now gone but jack persists
   // because of the wave reference to it and is now a free wave.

   return jack
End
```

Free Wave Created For User Function Input Parameter

If a user function takes a wave reference as in input parameter, you can create and pass a short free wave using a list of values as illustrated here:

```
Function Test(w)
   WAVE/D w
   Print w
End
```

You can invoke this function like this:

```
Test({1,2,3})
```

Igor automatically creates a free wave and passes it to Test. The free wave is automatically deleted when Test returns.

The data type of the free wave is determined by the type of the function's wave parameter. In this case the free wave is created as double-precision floating point because the wave parameter is defined using the /D flag. If /D were omitted, the free wave would be single-precision floating point. Wave/C/D would give a double-precision complex free wave. Wave/T would give a text free wave.

This list of values syntax is allowed only for user-defined functions because only they have code to test for and delete free waves upon exit.

Free Wave Lifetime

A free wave is automatically deleted when the last reference to it disappears.

Wave references can be stored in:

1. Wave reference variables in user-defined functions
2. Wave reference fields in structures
3. Elements of a wave reference wave (created by Make/WAVE)

The first case is the most common.

A wave reference disappears when:

1. The wave reference variable containing it is explicitly cleared using WaveClear.
2. The wave reference variable containing it is reassigned to refer to another wave.
3. The wave reference variable containing it goes out-of-scope and ceases to exist when the function in which it was created returns.
4. The wave reference wave element containing it is deleted or the wave reference wave is killed.

When there are no more references to a free wave, Igor automatically deletes it. This example illustrates the first three of these scenarios:

```
Function TestFreeWaveDeletion1()
   Wave w = NewFreeWave(2,3)  // Create a free wave with 3 points
   WaveClear w                // w no longer refers to the free wave
   // There are no more references to the free wave so it is deleted

   Wave w = NewFreeWave(2,3)  // Create a free wave with 3 points
   Wave w = root:wave0        // w no longer refers to the free wave
   // There are no more references to the free wave so it is deleted

   Wave w = NewFreeWave(2,3)  // Create a free wave with 3 points
End   // Wave reference w ceases to exist so the free wave is deleted
```

In the preceding example we used NewFreeWave which creates a free wave named 'f' that is not part of any data folder. Next we will use Make/FREE instead of NewFreeWave. Using Make allows us to give the free

wave a name of our choice but it is still free and not part of any data folder. When reading this example, keep in mind that "Make jack" creates an automatic wave reference variable named jack:

```
Function TestFreeWaveDeletion2()
   Make /D /N=3 /FREE jack    // Create a free DP wave with 3 points
   // Make created an automatic wave reference named jack

   Make /D /N=5 /FREE jack    // Create a free DP wave with 5 points
   // Make created an automatic wave reference named jack
   // which refers to the 5-point jack.
   // There are now no references to 3-point jack so it is automatically deleted.

End   // Wave reference jack ceases to exist so free wave jack is deleted
```

In the next example, a subroutine returns a reference to a free wave to the calling routine:

```
Function/WAVE Subroutine1()
   Make /D /N=3 /FREE jack=p  // Create a free DP wave with 3 points
   return jack                // Return reference to calling routine
End

Function MainRoutine1()
   WAVE w= Subroutine1()   // Wave reference w references the free wave jack
   Print w
End   // Wave reference w ceases to exist so free wave jack is deleted
```

In the final example, the wave jack starts as an object in a free data folder (see **Free Data Folders** on page IV-75). It is not free because it is part of a data folder hierarchy even though the data folder is free. When the free data folder is deleted, jack becomes a free wave.

When reading this example, keep in mind that the free data folder is automatically deleted when there are no more references to it. Originally, it survives because it is the current data folder and therefore is referenced by Igor internally. When it is no longer the current data folder, there are no more references to it and it is automatically deleted:

```
Function/WAVE Subroutine2()
   DFREF dfSav= GetDataFolderDFR()

   // Create free data folder and set as current data folder
   SetDataFolder NewFreeDataFolder()

   // Create wave jack and an automatic wave reference to it
   Make jack={1,2,3}    // jack is not free - it is an object in a data folder

   SetDataFolder dfSav  // Change the current data folder
   // There are now no references to the free data folder so it is deleted
   // but wave jack remains because there is a reference to it.
   // jack is now a free wave.

   return jack          // Return reference to free wave to calling routine
End

Function MainRoutine2()
   WAVE w= Subroutine2()   // Wave reference w references free wave jack
   Print w
End   // Wave reference w ceases to exist so free wave jack is deleted
```

Not shown in this section is the case of a free wave that persists because a reference to it is stored in a wave reference wave. That situation is illustrated by the **Automatic Parallel Processing with MultiThread** on page IV-283 example.

Converting a Free Wave to a Global Wave

You can use **MoveWave** to move a free wave into a global data folder, in which case it ceases to be free. If the wave was created by NewFreeWave its name will be 'f'. You can use MoveWave to provide it with a more descriptive name.

Here is an example illustrating Make/FREE:

```
Function Test()
   Make/FREE/N=(50,50) w
   SetScale x,-5,8,w
   SetScale y,-7,12,w
   w= exp(-(x^2+y^2))
   NewImage w
   if( GetRTError(1) != 0 )
      Print "Can't use a free wave here"
   endif
   MoveWave w,root:wasFree
   NewImage w
End
```

Note that MoveWave requires that the new wave name, wasFree in this case, be unique within the destination data folder.

To determine if a given wave is free or global, use the **WaveType** function with the optional selector = 2.

Free Data Folders

Free data folders are data folders that are not part of any data folder hierarchy. Their principal use is in multithreaded wave assignment using the MultiThread keyword in a function. They can also be used for temporary storage within functions.

Free data folders are recommended for advanced programmers only.

Free data folders require Igor Pro 6.1 or later.

Note: Free data folders are saved only in packed experiment files. They are not saved in unpacked experiments and are not saved by the SaveData operation or the Data Browser's Save Copy button. In general, they are intended for temporary computation purposes only.

You create a free data folder using the NewFreeDataFolder function. You access it using the data folder reference returned by that function.

After using SetDataFolder with a free data folder, be sure to restore it to the previous value, like this:

```
Function Test()
   DFREF dfrSave = GetDataFolderDFR()

   SetDataFolder NewFreeDataFolder()   // Create new free data folder.

   . . .

   SetDataFolder dfrSave
End
```

This is good programming practice in general but is especially important when using free data folders.

Free data folders can not be used in situations where global persistence is required such as in graphs, tables and controls. In other words, you should use objects in free data folders for short-term computation purposes only.

For a discussion of multithreaded assignment statements, see **Automatic Parallel Processing with MultiThread** on page IV-283. For an example using free data folders, see **Data Folder Reference MultiThread Example** on page IV-285.

Free Data Folder Lifetime

A free data folder is automatically deleted when the last reference to it disappears.

Data folder references can be stored in:

1. Data folder reference variables in user-defined functions
2. Data folder reference fields in structures
3. Elements of a data folder reference wave (created with Make/DF)
4. Igor's internal current data folder reference variable

A data folder reference disappears when:

1. The data folder reference variable containing it is explicitly cleared using KillDataFolder.
2. The data folder reference variable containing it is reassigned to refer to another data folder.
3. The data folder reference variable containing it goes out-of-scope and ceases to exist when the function in which it was created returns.
4. The data folder reference wave element containing it is deleted or the data folder reference wave is killed.
5. The current data folder is changed which causes Igor's internal current data folder reference variable to refer to another data folder.

When there are no more references to a free data folder, Igor automatically deletes it.

In this example, a free data folder reference variable is cleared by KillDataFolder:

```
Function Test1()
   DFREF dfr= NewFreeDataFolder()      // Create new free data folder.
   // The free data folder exists because dfr references it.
   . . .
   KillDataFolder dfr   // dfr no longer refers to the free data folder
End
```

KillDataFolder kills the free data folder only if the given DFREF variable contains the last reference to it.

In the next example, the free data folder is automatically deleted when the DFREF that references it is changed to reference another data folder:

```
Function Test2()
   DFREF dfr= NewFreeDataFolder()      // Create new free data folder.
   // The free data folder exists because dfr references it.
   . . .
   DFREF dfr= root:
   // The free data folder is deleted since there are no references to it.
End
```

In the next example, a free data folder is created and a reference is stored in a local data folder reference variable. When the function ends, the DFREF ceases to exist and the free data folder is automatically deleted:

```
Function Test3()
   DFREF dfr= NewFreeDataFolder()      // Create new free data folder.
   // The free data folder exists because dfr references it.
   . . .
End   // The free data folder is deleted because dfr no longer exists.
```

The fourth case, where a data folder reference is stored in a data folder reference wave, is discussed under **Data Folder Reference Waves** on page IV-65.

In the next example, the free data folder is referenced by Igor's internal current data folder reference variable because it is the current data folder. When the current data folder is changed, there are no more references to the free data folder and it is automatically deleted:

```
Function Test4()
   SetDataFolder NewFreeDataFolder()   // Create new free data folder.
   // The free data folder persists because it is the current data folder
   // and therefore is referenced by Igor's internal
   // current data folder reference variable.
   . . .

   // Change Igor's internal current data folder reference
   SetDataFolder root:
   // The free data folder is since there are no references to it.
End
```

Free Data Folder Objects Lifetime

Next we consider what happens to objects in a free data folder when the free data folder is deleted. In this event, numeric and string variables in the free data folder are unconditionally automatically deleted. A wave is automatically deleted if there are no wave references to it. If there is a wave reference to it, the wave survives and becomes a free wave. Free waves are waves that exists outside of any data folder as explained under **Free Waves** on page IV-71.

For example:

```
Function Test()
   SetDataFolder NewFreeDataFolder()   // Create new free data folder.
   // The free data folder exists because it is the current data folder.

   Make jack      // Make a wave and an automatic wave reference

   . . .

   SetDataFolder root:
   // The free data folder is deleted since there are no references to it.
   // Because there is a reference to the wave jack, it persists
   // and becomes a free wave.

   . . .

End   // The wave reference to jack ceases to exist so jack is deleted
```

When this function ends, the reference to the wave jack ceases to exist, there are no references to jack, and it is automatically deleted.

Next we look at a slight variation. In the following example, Make does not create an automatic wave reference because of the use of $, and we do not create an explicit wave reference:

```
Function Test()
   SetDataFolder NewFreeDataFolder()   // Create new free data folder.
   // The free data folder exists because it is the current data folder.

   Make $"jack"         // Make a wave but no wave reference
   // jack persists because the current data folder references it.

   . . .

   SetDataFolder root:
   // The free data folder is since there are no references to it.
   // jack is also deleted because there are no more references to it.
```

```
   . . .

End
```

Converting a Free Data Folder to a Global Data Folder

You can use **MoveDataFolder** to move a free data folder into the global hierarchy. The data folder and all of its contents then become global. The name of a free data folder created by NewFreeDataFolder is 'free-root'. You should rename it after moving to a global context. For example:

```
Function Test()
   DFREF saveDF = GetDataFolderDFR()
   DFREF dfr = NewFreeDataFolder()     // Create free data folder
   SetDataFolder dfr                   // Set as current data folder
   Make jack=sin(x/8)                  // Create some data in it
   SetDataFolder saveDF                // Restore original current data folder
   MoveDataFolder dfr, root:           // Free DF becomes root:freeroot
   RenameDataFolder root:freeroot,TestDF  // Rename with a proper name
   Display root:TestDF:jack
End
```

Note that MoveDataFolder requires that the data folder name, freeroot in this case, be unique within the destination data folder.

Structures in Functions

You can define structures in procedure files and use them in functions. Structures can be used only in user-defined functions as local variables and their behavior is defined almost entirely at compile time. Runtime or interactive definition and use of structures is not currently supported (for this purpose, use Data Folders (see Chapter II-8, **Data Folders**), the **StringByKey** function (see page V-675), or the **NumberByKey** function (see page V-458)).

Use of structures is an advanced technique. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

Defining Structures

Structures are defined in a procedure file with the following syntax:

```
Structure structureName
   memType memName [arraySize] [, memName [arraySize]]
   …
EndStructure
```

Structure member types (*memType*) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, DFREF, FUNCREF, or STRUCT. The DFREF object type requires Igor Pro 6.1 or later.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

Igor Member Type	C Equivalent	Byte Size
char	signed char	1
uchar	unsigned char	1
int16	short int	2
uint16	unsigned short int	2
int32	long int	4
uint32	unsigned long int	4

Igor Member Type	C Equivalent	Byte Size
float	float	4
double	double	8

The Variable and double types are identical although Variable can be also specified as complex (using the /C flag).

The optional *arraySize* must be specified using an expression involving literal numbers or locally-defined constants enclosed in brackets. The value must be between 1 and 400 for all but STRUCT where the upper limit is 100. The upper limit is a consequence of how memory is allocated on the stack frame.

Structures are two-byte aligned. This means that if an odd number of bytes has been allocated and then a nonchar field is defined, an extra byte of padding will be inserted in front of the new field. This is mainly of concern only when reading and writing structures from and to disk files.

The Structure keyword can be preceded with the **Static** keyword (see page V-594) to make the definition apply only to the current procedure window. Without the Static designation, structures defined in one procedure window may be used in any other.

Using Structures

To use ("instantiate") a structure in a function, you must allocate a STRUCT variable using:

```
STRUCT sName name
```

where *sName* is the name (or "tag" if you're a C programmer) of an existing structure and *name* is the local variable name (sometimes called the "instance name"). (See **STRUCT** on page V-678 for details.)

To access a member of a structure, specify the STRUCT variable name followed by a "." and the member name:

```
STRUCT Point pt
pt.v= 100
```

When a member is defined as an array:

```
Structure mystruct
   Variable var1
   Variable var2[10]
   …
EndStructure
```

you must specify `[index]` to use a given element in the array:

```
STRUCT mystruct ms
ms.var2[n]= 22
```

Structure and field names must be literal and can not use `$str` notation. The *index* value can be calculated at runtime (it doesn't have to be a literal number). If the field is itself a STRUCT, continue to append "." and field names as needed. See the **Example** on page IV-80.

You can define an array of structures as a field in a structure:

```
Structure mystruct
   STRUCT Point pt[100]    // Allowed as a sub-structure
EndStructure
```

However, you can not define an array of structures as a local variable in a function:

```
STRUCT Point pt[100]       // Not allowed as a function local variable
```

WAVE, NVAR, SVAR, and FUNCREF members can be initialized using the same syntax as used for the corresponding nonstructure variables. See **Runtime Lookup of Globals** on page IV-50 and **Function References** on page IV-84.

Structures may be passed to functions **only** by reference (as with Fortran), which allows them to be both input and output parameters (see **Pass-By-Reference** on page IV-45). The syntax is:

```
STRUCT sName  &varName
```

In a user function you define the input parameter:

```
Function myFunc(s)
   STRUCT mystruct &s
   …
End
```

Char and uchar arrays can be treated as zero-terminated strings by leaving off the brackets. Because the Igor compiler knows the size, the entire array can be used with no zero termination. Like normal string variables, concatenation using += is allowed but substring assignment using `[p1,p2]= subStr` is not supported.

Structures, including substructures, may be copied using simple assignment from one structure to the other. The source and destination structures must defined using the same structure name (tag).

The **Print** operation (see page V-498) can print individual elements of a structure or can print a summary of the entire STRUCT variable.

Example

Here is a (somewhat contrived) example using structures. Try executing `foo(2)`:

```
Constant kCaSize= 5

Structure substruct
   Variable v1
   Variable v2
EndStructure

Structure mystruct
   Variable var1
   Variable var2[10]
   String s1
   WAVE fred
   NVAR globVar1
   SVAR globStr1
   FUNCREF myDefaultFunc afunc
   STRUCT substruct ss1[3]
   char ca[kCaSize+1]
EndStructure

Function foo(n)
   Variable n

   Make/O/N=20 fred
   Variable/G globVar1= 111
   String/G aGlobStr="a global string var"

   STRUCT mystruct ms
   ms.var1= 11
   ms.var2[n]= 22
   ms.s1= "string s1"
   WAVE ms.fred     // could have =name if want other than waves named fred
   NVAR ms.globVar1
   SVAR ms.globStr1= aGlobStr
   FUNCREF myDefaultFunc ms.afunc= anotherfunc
   ms.ss1[n].v1= ms.var1/2
   ms.ss1[0]= ms.ss1[n]
   ms.ca= "0123456789"
   bar(ms,n)
   print ms.var1,ms.var2[n],ms.s1,ms.globVar1,ms.globStr1,ms.ss1[n].v1
   print ms.ss 1[n].v2,ms.ca,ms.afunc()
   print "a whole wave",ms.fred
   print "the whole ms struct:",ms

   STRUCT substruct ss
   ss= ms.ss1[n]
```

```
   print "copy of substruct",ss
End

Function bar(s,n)
   STRUCT mystruct &s
   Variable n

   s.ss1[n].v2= 99
   s.fred= sin(x)
   Display s.fred
End

Function myDefaultFunc()
   return 1
End

Function anotherfunc()
   return 2
End
```

Note the use of WAVE, NVAR, SVAR and FUNCREF in the function foo. These keywords are required both in the structure definition and again in the function, when the structure members are initialized.

Built-In Structures

Igor includes a few special purpose, predefined structures for use with certain operations. Some of those structures use these predefined general purpose structures:

```
Structure Rect
   Int16 top,left,bottom,right
EndStructure

Structure Point
   Int16 v,h
EndStructure

Structure RGBColor
   UInt16 red, green, blue
EndStructure
```

A number of operations use built-in structures that the Igor programmer can use. See the command reference information for details about these structures and their members.

Operation	Structure Name
Button	**WMButtonAction**
CheckBox	**WMCheckboxAction**
CustomControl	**WMCustomControlAction**
ListBox	**WMListboxAction**
ModifyFreeAxis	**WMAxisHookStruct**
PopupMenu	**WMPopupAction**
SetVariable	**WMSetVariableAction**
SetWindow	**WMWinHookStruct**
Slider	**WMSliderAction**
TabControl	**WMTabControlAction**

Applications of Structures

Structures are useful for reading and writing disk files. The **FBinRead** operation (see page V-153) and the **FBinWrite** operation (see page V-154) understand structure variables and will read or write the entire structure from or to a disk file. The individual fields of the structure will be byte-swapped if you use the /B flag.

Structures can be used in complex programming projects to reduce the dependency on global objects and to simplify passing data to and getting data from functions. For example, a base function might allocate a local structure variable and then pass that variable on to a large set of lower level routines. Because structure variables are passed by reference, data written into the structure by lower level routines is available to the higher level. Without structures, you would have to pass a large number of individual parameters or use global variables and data folders.

Using Structures with Windows and Controls

Predefined structures are available for "new-style" (new as of Igor Pro 5) action procedures for controls and hook functions for windows. See the documentation for each of the individual control listed in Chapter III-14, **Controls and Control Panels** and in Chapter V-1, **Igor Reference**, and the **SetWindow** operation (see page V-569).

Advanced programmers should also be aware of userdata that can be associated with windows using the **SetWindow** operation (see page V-569). Userdata is binary data that persists with individual windows; it is suitable for storing structures. Storing structures in a window's userdata is very handy in eliminating the need for global variables and reduces the bookkeeping needed to synchronize those globals with the window's life cycle. Userdata is also available for use with controls. See the **ControlInfo** operation (see page V-63), **GetWindow** operation (see page V-225), **GetUserData** operation (see page V-224), and **SetWindow** operation (see page V-569) operations.

Example

Here is an example illustrating Igor- and user-defined structures along with userdata in a control. Put the following in the procedure window of a new experiment and run the Panel0 macro. Then click on the buttons. Note that the buttons will remember their state even if the experiment is saved and reloaded. To fully understand this example, examine the definition of WMButtonAction in the **Button** operation (see page V-38).

```
#pragma rtGlobals=1        // Use modern global access method.

Structure mystruct
   Int32 nclicks
   double lastTime
EndStructure

Function ButtonProc(bStruct) : ButtonControl
   STRUCT WMButtonAction &bStruct

   if( bStruct.eventCode != 1 )
      return 0         // we only handle mouse down
   endif

   STRUCT mystruct s1
   if( strlen(bStruct.userdata) == 0 )
      print "first click"
   else
      StructGet/S s1,bStruct.userdata
      String ctime= Secs2Date(s1.lastTime, 1 )+" "+Secs2Time(s1.lastTime,1)
   // Warning: Next command is wrapped to fit on the page.
      printf "button %s clicked %d time(s), last click =
%s\r",bStruct.ctrlName,s1.nclicks,ctime
   endif
   s1.nclicks += 1
   s1.lastTime= datetime
   StructPut/S s1,bStruct.userdata
   return 0
End

Window Panel0() : Panel
   PauseUpdate; Silent 1         // building window…
   NewPanel /W=(150,50,493,133)
```

```
   SetDrawLayer UserBack
   Button b0,pos={12,8},size={50,20},proc=ButtonProc,title="Click"
   Button b1,pos={65,8},size={50,20},proc=ButtonProc,title="Click"
   Button b2,pos={119,8},size={50,20},proc=ButtonProc,title="Click"
   Button b3,pos={172,8},size={50,20},proc=ButtonProc,title="Click"
   Button b4,pos={226,8},size={50,20},proc=ButtonProc,title="Click"
EndMacro
```

Limitations of Structures

Although structures can reduce the need for global variables, they do not eliminate them altogether. A structure variable, like all local variables in functions, disappears when its host function returns. In order to maintain state information, you will need to store and retrieve structure information using global variables. You can do this using a global variable for each field or, with certain restrictions, you can store entire structure variables in a single global using the **StructPut** operation (see page V-679) and the **StructGet** operation (see page V-679).

As of Igor Pro 5.03, a structure can be passed to an external operation or function. See the Igor XOP Toolkit manual for details.

Static Functions

You can create functions that are local to the procedure file in which they appear by inserting the keyword *Static* in front of *Function* (see **Static** on page V-594 for usage details). The main reason for using this technique is to minimize the possibility of your function names conflicting with other names. You can use common intuitive names instead of devising a special and sometimes ugly naming strategy.

Functions normally have global scope and are available in any part of an Igor experiment, but the static keyword limits the scope of the function to its procedure file and hides it from all other procedure files. Static functions can only be used in the file in which they are defined. They can not be called from the command line and they cannot be accessed from macros.

Because static functions cannot be executed from the command line, you will have write a public test function to test them.

You can break this rule and access a static function using a module name (see **Regular Modules** on page IV-212). This technique can test the function from the command line.

Non-static functions (functions without the static keyword) are sometimes called “public” functions.

ThreadSafe Functions

ThreadSafe user functions provide support for computers with multiple processors and can be used for preemptive multitasking background tasks. A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads.

Note: Writing a multitasking program is for expert programmers only. Intermediate programmers can write thread-safe curve-fitting functions and multithreaded assignment statements (see **Automatic Parallel Processing with MultiThread** on page IV-283). Beginning programmers should gain experience with regular programming before using multitasking.

You can create thread safe functions by inserting the keyword `ThreadSafe` in front of `Function`. For example:

```
ThreadSafe Function myadd(a,b)
   Variable a,b

   return a+b
End
```

Only a subset of functions and operations can be used in a ThreadSafe function. Generally, all numeric or utility functions can be used but those that access windows can not. To determine if a routine is ThreadSafe, use the Command Help tab of the Help Browser.

Although file operations are listed as ThreadSafe, they have certain limitations when running in a ThreadSafe function. If a file load hits a condition that normally would need user assistance, the load is aborted. No printing to history is done and there is no support for symbolic paths (use **PathInfo** and pass the path as a string input parameter).

ThreadSafe functions can call other ThreadSafe functions but may not call non-ThreadSafe functions. Non-ThreadSafe functions can call ThreadSafe functions.

When ThreadSafe functions execute in the main thread, they have normal access to data folders, waves, and variables. But when running in a preemptive thread, ThreadSafe functions use their own private data folders, waves, and variables. When a thread is started, waves can be passed to the function as input parameters. Such waves are then flagged as being in use by the thread, which prevents any changes to the size of the wave. When all threads under a given main thread are finished, the waves return to normal. You can pass data folders between the main thread and preemptive threads but such data folders are never shared.

See **ThreadSafe Functions and Multitasking** on page IV-288 for a discussion of programming with preemptive multitasking threads.

Function Overrides

In some rare cases, you may need to temporarily change an existing function. When that function is part of a package provided by someone else (or by WaveMetrics) it may be undesirable or difficult to edit the original function. By using the keyword "Override" in front of "Function" you can define a new function that will be used in place of another function of the same name that is defined in a *different and later* procedure file.

Although it is difficult to determine the order in which procedure files are compiled, the main procedure window is always first. Therefore, always define override functions in the main procedure file.

Although you can override static functions, you may run into a few difficulties. If there are multiple files with the same static function name, your override will affect all of them, and if the different functions have different parameters then you will get a link error.

Here is an example of the Override keyword. In this example, start with a new experiment and create a new procedure window. Insert the following in the new window (not the main procedure window).

```
Function foo()
   print "this is foo"
End

Function Test()
   foo()
End
```

Now, on the command line, execute Test(). You will see "this is foo" in the history.

Open the main procedure window and insert the following:

```
Override Function foo()
   print "this is an override version of foo"
End
```

Now execute Test() again. You will see the "this is an override version of foo" in the history.

Function References

Function references provide a way to pass a function to a function. This is a technique for advanced programmers. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

To specify that an input parameter to a function is a function reference, use the following syntax:

```
Function Example(f)
   FUNCREF myprotofunc f
   . . .
End
```

This specifies that the input parameter f is a function reference and that a function named myprotofunc specifies the kind of function that is legal to pass. The calling function passes the name of a function as the f parameter. The called function can use f just as it would use the prototype function.

If a valid function is not passed then the prototype function will be called instead. The prototype function can either be a default function or it can contain error handling code that makes it obvious that a proper function was not passed.

A similar syntax can be used to create function reference variables in the body of a function:

```
FUNCREF protoFunc f = funcName
FUNCREF protoFunc f = $"str"
FUNCREF protoFunc f = funcRef
```

As shown, the right hand side can take either a literal function name, a $ expression that evaluates to a function name at runtime, or it can take another FUNCREF variable.

FUNCREF variables can refer to external functions as well as user functions. However, the prototype function must be a user function and it must not be static.

Although you can store a reference to a static function in a FUNCREF variable, you can not then use that variable with Igor operations that take a function as an input. FuncFit is an example of such an operation.

Following are some example functions and FUNCREFs that illustrate several concepts:

```
Function myprotofunc(a)
   Variable a

   print "in myprotofunc with a= ",a
End

Function foo1(var1)
   Variable var1

   print "in foo1 with a= ",var1
End

Function foo2(a)
   Variable a

   print "in foo2 with a= ",a
End

Function foo3(a)
   Variable a

   print "in foo3 with a= ",a
End

Function badfoo(a,b)
   Variable a,b

   print "in badfoo with a= ",a
End

Function bar(a,b,fin)
   Variable a,b
   FUNCREF myprotofunc fin
```

```
   if( a==1 )
      FUNCREF myprotofunc f= foo1
   elseif( a==2 )
      FUNCREF myprotofunc f= $"foo2"
   elseif( a==3 )
      FUNCREF myprotofunc f= fin
   endif
   f(b)
End
```

For the above functions, the following table shows the results for various invocations of the bar function executed on the command line:

Command	Result
bar(1,33,foo3)	in foo1 with a= 33
bar(2,44,foo3)	in foo2 with a= 44
bar(3,55,foo3)	in foo3 with a= 55
bar(4,55,foo3)	in myprotofunc with a= 55

Executing `bar(3,55,badfoo)` will generate a syntax error dialog that will highlight "badfoo" in the command. This error results because the format of the badfoo function does not match the format of the prototype function, myprotofunc.

Conditional Compilation

Compiler directives can be used to conditionally include or exclude blocks of code. This is especially useful when an XOP may or may not be available. It is also convenient for testing and debugging code. For example, to enable a block of procedure code depending on the presence or absence of an XOP use

```
#if Exists("nameOfAnXopRoutine")
   <proceedure code using XOP routines>
#endif
```

The conditional compiler directives are modeled after the C/C++ language. Unlike other #keyword directives, these may be indented. For defining symbols, the directives are:

```
#define symbol

#undef symbol
```

For conditional compilation, the directives are:

```
#ifdef symbol

#ifndef symbol

#if expression

#elif expression

#else

#endif
```

Expressions are ordinary Igor expressions, but cannot involve any user-defined objects. They evaluate to TRUE if the absolute value is > 0.5.

Conditionals must be either completely outside or completely inside function definitions; they cannot straddle a function definition. Conditionals cannot be used within macros but the **defined** function can.

Nesting depth is limited to 16 levels. Trailing text other than a comment is illegal.

Note that #define is used purely for defining symbols (there is nothing like C's preprocessor) and the only use of a symbol is with #if, #ifdef, #ifndef and the defined function.

The defined function was added in Igor Pro 6.20 allowing the use of:

```
#if defined(symbol)
```

Unlike C, you cannot use `#if defined(`*`symbol`*`)`.

Symbols exist only in the file where they are defined; the only exception is for symbols defined in the main procedure window, which are available to all other procedures except independent modules. In addition, you can define global symbols that are available in all procedure windows (including independent modules) using:

```
SetIgorOption poundDefine=symb
```

This adds one symbol to a global list. You can query the global list using:

```
SetIgorOption poundDefine=symb?
```

This sets V_flag to TRUE if symb exists. To remove a symbol from the global list use:

```
SetIgorOption poundUndefine=symb
```

For non-independent module procedure windows, a symbol is defined if it exists in the global list *or* in the main procedure window's list *or* in the given procedure window.

For independent module procedure windows, a symbol is defined if it exists in the global list *or* in the given procedure window; it does not use the main procedure window list.

A symbol defined in a global list is not undefined by a #undef in a procedure window.

Predefined Global Symbols

As of Igor Pro 6.20, the following global symbols are automatically predefined as appropriate, and available in all procedure windows:

Symbol	Automatically Predefined If
MACINTOSH	The Igor application is a Macintosh application.
WINDOWS	The Igor application is a Windows application.
IGOR64	The Igor application is a 64-bit application.

Conditional Compilation Examples

```
#define MYSYMBOL

#ifdef MYSYMBOL

Function foo()
   print "This is foo when MYSYMBOL is defined"
End

#else

Function foo()
   print "This is foo when MYSYMBOL is NOT defined"
End

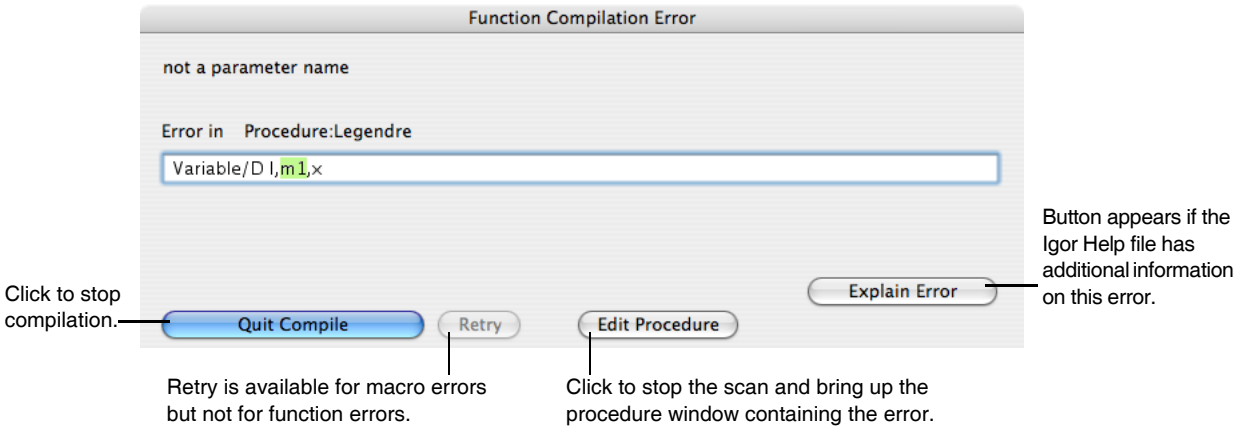
#endif   // MYSYMBOL

// This works in Igor Pro 6.20 or later
#if defined(MACINTOSH)
   <conditionally compiled code here>
#endif
```

```
// This works in Igor Pro 6.00 or later
#if CmpStr("Macintosh",IgorInfo(2)) == 0
   <conditionally compiled code here>
#endif
```

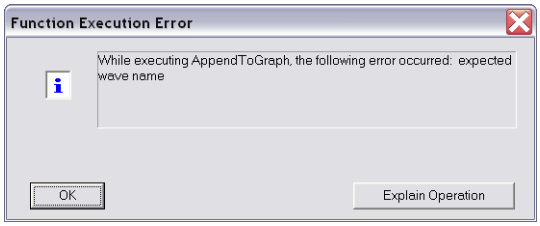
Function Errors

During function compilation, Igor checks and reports syntactic errors and errors in parameter declarations. The normal course of action is to edit the offending function and try to compile again.



Runtime errors in functions are not reported on the spot. Instead, Igor saves information about the error and function execution continues. Igor presents an error dialog only after the last function ceases execution and Igor returns to the idle state. If multiple runtime errors occur, only the first is reported.

When a runtime error occurs, after function execution ends, Igor will present a dialog:



In this example, we tried to pass to the AppendToGraph function a reference to a wave that did not exist. To find the source of the error, you should use Igor's debugger and set it to break on error (see **Debugging on Error** on page IV-185 for details).

Sophisticated programmers may want to detect and deal with runtime errors on their own. The **GetRTError** function (see page V-221) can be used to check if an error occurred, and optionally to clear the error so that Igor doesn't report it.

Coercion in Functions

The term "coercion" means the conversion of a value from one numeric precision or numeric type to another. Consider this example:

```
Function foo(awave)
   WAVE/C awave

   Variable/C var1
```

```
   var1= awave[2]*cmplx(2,3)
   return real(var1)
End
```

The parameter declaration specifies that awave is complex. You can pass any kind of wave you like but it will be coerced into complex before use. For example, if you pass a real valued integer wave the value at point index 2 will be converted to double precision and zero will be used for the imaginary part.

Operations in Functions

You can call most operations from user-defined functions. To provide this capability, WaveMetrics had to create special code for each operation. Some operations weren't worth the trouble or could cause problems. If an operation can't be invoked from a function, an error message is displayed when the function is compiled. The operations that can't be called from a function are:

AppendToLayout	Layout	Modify	OpenProc
PrintGraphs	Quit	See Also	Stack
StackWindows	Tile	TileWindows	

If you need to invoke one of these operations from a user-defined function, use the Execute operation. See **The Execute Operation** on page IV-176.

Note that the ModifyGraph, ModifyTable and ModifyLayout operations *can* be called from a function.

Also, you can use the **NewLayout** operation (see page V-437) instead of Layout, the **AppendLayoutObject** operation (see page V-23) instead of AppendToLayout, and the **RemoveLayoutObjects** operation (see page V-518) instead of RemoveFromLayout.

External operations implemented by old XOPs also can not be called directly from user-defined functions. Again, the solution is to use the Execute operation.

Updates During Function Execution

An update is an action that Igor performs which consists of:

- Reexecuting formulas for dependent objects whose antecedents have changed (see Chapter IV-9, **Dependencies**);
- Redrawing graphs and tables which display waves that have changed;
- Redrawing page layouts containing graphs, tables, or annotations that have changed;
- Redrawing windows that have been uncovered.

When no procedure is executing, Igor continually checks whether an update is needed and does an update if necessary.

When a function is executing, Igor does no automatic updates at all. However, you can force an update by calling the **DoUpdate** operation (see page V-121). Call DoUpdate if you don't want to wait for the next automatic update which will occur when function execution finishes.

Aborting Functions

There are two ways to prematurely stop procedure execution: a user abort or a programmed abort. Both stop execution of all procedures, no matter how deeply nested.

On Macintosh, you can abort procedure execution by pressing Command-period. On Windows, press Ctrl+Break or click the Abort button in the status bar. You may need to hold the keys down for a while because Igor looks at the keyboard periodically and if you don't press the keys long enough, Igor will not see them.

A user abort does not directly return. Instead it sets a flag that stops loops from looping and then returns using the normal calling chain. For this reason some code will still be executed after an abort but execution should stop quickly. This behavior releases any temporary memory allocations made during execution.

A **programmed abort** occurs during procedure execution according to conditions set by the programmer.

The simplest programmed abort occurs when the **Abort** operation (see page V-16) is executed. Here is an example:

```
if( numCells > 10 )
   Abort "Too many cells! Quitting."
endif
// code here doesn't execute if numCells > 10
```

Other programmed aborts can be triggered using the AbortOnRTE and AbortOnValue flow control keywords. The try-catch-endtry flow control construct can be used for catching and testing for aborts. See **Flow Control for Aborts** on page IV-38 for more details.

Legacy Code Issues

This section discusses changes that have occurred in Igor programming over the years. If you are writing new code, you don't need to be concerned with these issues. If you are working with existing code, you may run into some of them.

If you are just starting to learn Igor programming, you have enough to think about already, so it is a good idea to skip this section. Once you are comfortable with the modern techniques described above, come back and learn about these antiquated techniques.

Old-Style Comments and Compatibility Mode

As of Igor Pro 4.0, the old comment character, a vertical bar (|), has been replaced and should no longer be used when writing new procedures. In Igor Pro 4.0 and later, the | character is used as the bitwise OR operator (see **Operators** on page IV-5).

In order to run old procedures which use | as the comment symbol, Igor supports a compatibility mode. This mode is a property of an experiment. When the current experiment is in compatibility mode, Igor interprets | as a comment symbol. Normally, when the current experiment is not in compatibility mode, Igor interprets | as bitwise OR.

You put the current experiment in compatibility mode by executing the following on the command line:

```
Silent 100
```

You take the current experiment out of compatibility mode by executing:

```
Silent 101
```

When you execute these commands, Igor automatically recompiles all procedure files in the current experiment using the new mode.

All experiments created pre-Igor 4 are automatically in compatibility mode until you update them and their procedures.

We strongly recommend that you update old experiments and procedures so that you don't need to use compatibility mode. Until you do so, your old experiments will not work with new procedure files that use | as bitwise OR. Here are the steps to update an experiment and its procedures:

1. In each old procedure file, replace each | symbol that is used to introduce a comment with //.
   Use Edit→Find and Edit→Find Same to find each occurrence of |. Do not do a mass replace because you may inadvertently change a | symbol used in the old bitwise OR operator (%|, which is still supported) or in a string.
2. On the command line, take the experiment out of compatibility mode by executing:

```
Silent 101
```

Igor will recompile procedures.

3. If there are any remaining obsolete uses of |, Igor will display a compile error dialog. Fix the error and recompile the procedures until you get no more errors.

If you create procedure files that are used by other people (either in your group or for public use) and you want to use the new logic operations, such as | (bitwise OR) or || (logical OR), which require compatibility mode to be off (`Silent 101`), then you can specify

```
#pragma rtGlobals=2
```

in place of the normal `rtGlobals=1`.

If your procedure file is included in an experiment running in compatibility mode (`Silent 100`) then an alert dialog will be presented that will allow the user to turn compatibility mode off. However, keep in mind that when the procedures are recompiled in the new mode, the user's other procedures will generate errors if they use the obsolete comment symbol.

Text After Flow Control

Prior to Igor Pro 4, Igor ignored any extraneous text after a flow control statement. Such text was an error, but Igor did not detect it.

Igor now checks for extra text after flow control statements. When found, a dialog is presented asking the user if such text should be considered an error or not. The answer lasts for the life of the Igor session.

Because previous versions of Igor ignored this extra text, it may be common for existing procedure files to have this problem. The text may in many cases simply be a typographic error such as an extra closing parenthesis:

```
if( a==1 ))
```

In other cases, the programmer may have thought they were creating an elseif construct:

```
else if( a==2 )
```

even though the "if(a==2)" part was simply ignored. In some cases this may represent a bug in the programmer's code but most of the time it is asymptomatic.

Global Variables Used by Igor Operations

The section **Local Variables Used by Igor Operations** on page IV-47 explains that certain Igor operations create and set certain special local variables. That is true if the procedure file uses runtime lookup of globals (rtGlobals=1 is in effect). In very old procedure files that use the obsolete direct reference method of accessing variables, the operations create and set global variables.

Also explained in **Local Variables Used by Igor Operations** on page IV-47 is the fact that some operations, such as CurveFit, look for certain special local variables which modify the behavior of the operations. For historic reasons, operations that look for special variables will look for global variables in the current data folder if the local variable is not found. This is true whether rtGlobals=1 is in effect or not. This behavior is unfortunate and may be removed from Igor some day. New programming should use local variables for this purpose.

Direct Reference to Globals

The section **Accessing Global Variables and Waves** on page IV-50 explains how to access globals from a procedure file that uses runtime lookup of globals (rtGlobals=1 is in effect). This section explains accessing globals in very old procedure files that use the obsolete direct reference method of accessing variables.

Prior to Igor Pro 3, Igor required that globals referenced from functions had to exist when the function was compiled. This was called the "direct reference" method of accessing globals. In Igor Pro 3, a new method, called the "runtime lookup" method, was added.

In a particular procedure file, the presence of the statement:

```
#pragma rtGlobals = 1
```

specifies that the file uses the runtime lookup method. If this statement is absent, or if the number used is 0 instead of the usual 1, the file uses the old direct reference method.

All new programming should use the runtime lookup method and consequently all new procedure files should contain the rtGlobals pragma as shown above.

Future versions of Igor may remove the old method. Therefore Igor programmers should modify old procedure files to use it.

This section explains the old method. It is of interest only if you need to work with old files.

To compile a direct reference to a global, the global must exist at compile time. There are three ways to meet this requirement:

1. Create the global from the command line before compiling the procedures.
2. Declare the global in a function before the first use of the global.
3. Let Igor automatically create the global.

Method 1 works for waves, numeric variables and string variables. However, methods 2 and 3 work for numeric and string variables only, not for waves.

To use method 1, execute a Make, Variable, or String command from the command line before compiling procedures that refer to the global. This technique is not good for use with a separate utility procedure file because you would need to remember to create the globals each time you opened the file.

To use method 2, create a function at the top of the procedure file that declares all of the global variables used in the procedure file. For example:

```
#pragma rtGlobals=0        // Use old direct reference method

Function InitFilterProcGlobals()
   Variable/G gCutoffFrequency, gFilterType
   String/G gFilterErrorMessage

   gCutoffFrequency = 1.0
   gFilterType = 0
   gFilterErrorMessage = ""
End
```

This method works because, with rtGlobals=0, Igor creates the declared global variables and strings at compile time. When Igor compiles the Variable/G and String/G declarations, it creates the globals right then and there. Thus, the globals are guaranteed to exist when referenced later in this function or in any other function compiled after this function.

Although the globals are created at compile time, they will have default values (0 for numeric globals, "" for string globals) until the function actually runs. Compile-time declaration creates the globals but does not set their initial values.

Method number 3 occurs automatically when you compile, with rtGlobals=0, an operation (e.g., WaveStats) that returns results via global variables. Therefore the following will compile without error:

```
#pragma rtGlobals=0        // Use old direct reference method

Function WaveStdDev(w)
   WAVE w

   WaveStats/Q w
   return V_sdev
End
```

V_sdev is one of many global variable created by the WaveStats operation at compile time (if rtGlobals=0 is in effect) but set to a value at runtime. Thus, when you compile WaveStats in a function, Igor creates these global variables.

By default (if a given procedure file contains no rtGlobals statement), rtGlobals=0 is in effect. The "#pragma rtGlobals=1" statement affects only the procedure file in which it appears. If you enter it in your main procedure window, it will not affect any other included or explicitly opened procedure files. Use this to modernize one procedure file at a time.

The rtGlobals pragma can appear anywhere in the procedure file, even inside a function, and it can appear more than once. However, it should be sufficient in nearly all cases to have just one rtGlobals pragma near the beginning of the file.

Here are the steps for converting a procedure file to use the runtime lookup method for accessing globals:

1. Insert the #pragma rtGlobals=1 statement, with no indentation, at or near the top of the procedure in the file.
2. Click the Compile button to compile the procedures.
3. If you use direct reference to access a global, Igor will display an error dialog indicating the line on which the error occurred. Add an NVAR, SVAR or WAVE reference.
4. If you encountered an error in step 3, return to step 2.

Chapter
IV-4

Macros

Overview

When we first created Igor, some time in the last millennium, it supported automation through macros. The idea of the macro was to allow users to collect commands into conveniently callable routines. Igor interpreted and executed each command in a macro as if it were entered in the command line.

WaveMetrics soon realized the need for a faster, more robust technology that would support full-blown programming. This led to the addition of user-defined functions. Because functions are compiled, they execute much more quickly. Also, compilation allows Igor to catch syntactic errors sooner. Functions have a richer set of flow control capabilities and support many other programming refinements. Over time, the role of macros has diminished in favor of functions.

Macros are still supported and there are still a few uses in which they are preferred. When you close a graph, table, page layout, or control panel, Igor offers to automatically create a window recreation macro which you can later run to resurrect the window. You can also ask Igor to automatically create a window style macro using the Window Control dialog. The vast majority of programming, however, should be done using functions.

The syntax and behavior of macros are similar to the syntax and behavior of functions, but the differences can be a source of confusion for someone first learning Igor programming. If you are just starting, you can safely defer reading the rest of this chapter until you need to know more about macros, if that time ever comes.

Comparing Macros and Functions

Like functions, macros are created by entering text in procedure windows. Each macro has a name, a parameter list, parameter declarations, and a body. Unlike functions, a macro has no return value.

Macros and functions use similar syntax. Here is an example of each. To follow along, open the Procedure window (Windows menu) and type in the macro and function definitions.

```
Macro MacSayHello(name)
   String name

   Print "Hello "+name
End

Function FuncSayHello(name)
   String name

   Print "Hello "+name
End
```

Now click in the Command window to bring it to the front. Use this to type commands into the command line and to compile the Procedure window.

If you execute the following on the command line

```
MacSayHello("John"); FuncSayHello("Sue")
```

you will see the following output printed in the history area:

```
Hello John
Hello Sue
```

This example may lead you to believe that macros and functions are nearly identical. In fact, there are a lot of differences. The most important differences are:

- Macros automatically appear in the Macros menu. Functions must be explicitly added to a menu, if desired, using a menu definition.
- Most errors in functions are detected when procedures are compiled. Most errors in macros are detected when the macro is executed.
- Functions run a lot faster than macros.
- Functions support wave parameters, for loops and switches while macros do not.

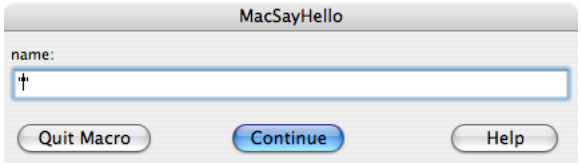
- Functions have a richer syntax.

If you look in the Macros menu, you will see MacSayHello but not FuncSayHello.

If you execute "`FuncSayHello()`" on the command line you will see an error dialog. This is because you must supply a parameter. You can execute, for example:

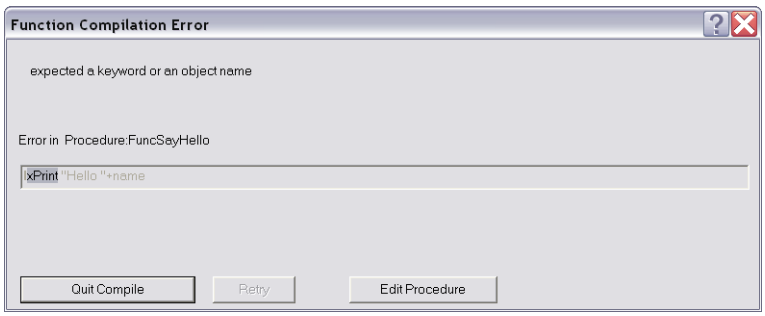
```
FuncSayHello("Sam")
```

On the other hand, if you run MacSayHello from the Macros menu or if you execute "`MacSayHello()`" on the command line, you will see a dialog that you use to enter the name before continuing:



This is called the "missing parameter dialog". It is described under **The Missing Parameter Dialog** on page IV-101. Functions can display a similar dialog, called a simple input dialog, with a bit of additional programming.

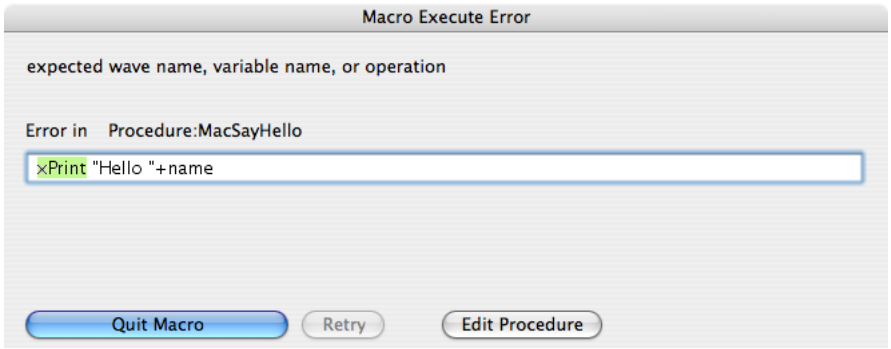
Now try this: In both procedures, change "Print" to "xPrint". Then click in the command window. You will see a dialog like this:



Click the Edit Procedure button and change "xPrint" back to "Print" in the function but not in the macro. Then click in the command window.

Notice that no error was reported once you fixed the error in the function. This is because only functions are compiled and thus only functions have their syntax completely checked at compile time. Macros are interpreted and most errors are found only when the line in the procedure window in which they occur is executed. To see this, run the macro by executing "`MacSayHello("Sam")`" on the command line.

You will then see this dialog:



Notice the box around the line containing the error. This box means you can edit its contents. If you change "xPrint" to "Print" in this dialog you will see that the Retry button becomes enabled. If you click this button,

you can continue execution of the macro. When the macro finishes, take a look at the Procedure window. You will notice that the correction you made in the dialog was put in the Procedure window and your "broken" macro is now fixed.

Macro Syntax

Here is the basic syntax for macros.

```
<Defining keyword> <Name> ( <Input parameter list> ) [:<Subtype>]
   <Input parameter declarations>

   <Local variable declarations>

   <Body code>
End
```

The Defining Keyword

<Defining keyword> is one of the following:

Defining Keyword	Creates Macro In
Window	Windows menu.
Macro	Macros menu.
Proc	—

The Window keyword is used by Igor when it automatically creates a window recreation macro. Except in rare cases, you will not write window recreation macros but instead will let Igor create them automatically.

The Procedure Name

The names of macros must follow the standard Igor naming conventions. Names can consist of up to 31 characters. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names must not conflict with the names of other Igor objects, functions or operations. Names in Igor are case insensitive.

The Procedure Subtype

You can identify procedures designed for specific purposes by using a subtype. Here is an example:

```
Proc ButtonProc(ctrlName) : ButtonControl
   String ctrlName

   Beep
End
```

Here, "`: ButtonControl`" identifies a macro intended to be called when a user-defined button control is clicked. Because of the subtype, this macro is added to the menu of procedures that appears in the Button Control dialog. When Igor automatically generates a procedure it generates the appropriate subtype. See **Procedure Subtypes** on page IV-179 for details.

The Parameter List and Parameter Declarations

The parameter list specifies the name for each input parameter. Macros have a limit of 10 parameters.

The parameter declaration must declare the type of each parameter using the keywords `Variable` or `String`. If a parameter is a complex number, it must be declared `Variable/C`.

Note: There should be no blank lines or other commands until after all the input parameters are defined. There should be one blank line after the parameter declarations, before the rest of the procedure. Igor will report errors if these conditions are not met.

Variable and string parameters in macros are always passed to a subroutine by value.

When macros are invoked with some or all of their input parameters missing, Igor displays a missing parameter dialog to allow the user to enter those parameters. In the past this has been a reason to use macros. However, as of Igor Pro 4, functions can present a similar dialog to fetch input from the user, as explained under **The Simple Input Dialog** on page IV-122.

Local Variable Declarations

The input parameter declarations are followed by the local variable declarations if the macro uses local variables. Local variables exist only during the execution of the macro. They can be numeric or string and are declared using the `Variable` or `String` keywords. They can optionally be initialized. Here is an example:

```
Macro Example(p1)
   Variable p1

   // Here are the local variables
   Variable v1, v2
   Variable v3=0
   Variable/C cv1=cmplx(0,0)
   String s1="test", s2="test2"

   <Body code>
End
```

If you do not supply explicit initialization, Igor automatically initializes local numeric variables with the value zero and local string variables with the value "".

The name of a local variable is allowed to conflict with other names in Igor although they must be unique within the macro. Clearly if you create a local variable named “sin” then you will be unable to use Igor’s built-in sin function within the macro.

You can declare a local variable in any part of a macro with one exception. If you place a variable declaration inside a loop in a macro then the declaration will be executed multiple times and Igor will generate an error since local variable names must be unique.

Body Code

The local variable declarations are followed by the body code. This table shows what can appear in body code of a macro.

What	Allowed in Macros?	Comments
Assignment statements	Yes	Includes wave, variable and string assignments.
Built-in operations	Yes	
External operations	Yes	
External functions	Yes	
Calls to user functions	Yes	
Calls to macros	Yes	
if-else-endif	Yes	
if-elseif-endif	No	
switch-case-endswitch	No	
strswitch-case-endswitch	No	
try-catch-endtry	No	
structures	No	
do-while	Yes	
for-endfor	No	

What	Allowed in Macros?	Comments
Comments	Yes	Comments start with //.
break	Yes	Used in loop statements.
continue	No	
default	No	
return	Yes, but with no return value.	

Conditional Statements in Macros

The conditional if-else-endif statement is allowed in macros. It works the same as in functions. See **If-Else-Endif** on page IV-31.

Loops in Macros

The do-while loop is supported in macros. It works the same as in functions. See **Do-While Loop** on page IV-36.

Return Statement in Macros

The return keyword immediately stops executing the current macro. If it was called by another macro, control returns to the calling macro.

A macro has no return value so return is used just to prematurely quit the macro. Most macros will have no return statement.

Invoking Macros

There are several ways to invoke a macro:

- From the command line
- From the Macros, Windows or user-defined menus
- From another macro
- From a button or other user control

The menu in which a macro appears, if any, is determined by the macro's type and subtype.

This table shows how a macro's type determines the menu that Igor puts it in.

Macro Type	Defining Keyword	Menu
Macro	`Macro`	Macros menu
Window Macro	`Window`	Windows menu
Proc	`Proc`	—

If a macro has a subtype, it may appear in a different menu. This is described under **Procedure Subtypes** on page IV-179. You can put macros in other menus as described in Chapter IV-5, **User-Defined Menus**.

You can not directly invoke a macro from a user function. You can invoke it indirectly, using the **Execute** operation (see page V-145).

Using $ in Macros

As shown in the following example, the $ operator can create references to global numeric and string variables as well as to waves.

```
Macro MacroTest(vStr, sStr, wStr)
   String vStr, sStr, wStr

   $vStr += 1
   $sStr += "Hello"
   $wStr += 1
End

Variable/G gVar = 0; String/G gStr = ""; Make/O/N=5 gWave = p
MacroTest("gVar", "gStr", "gWave")
```

See **String Substitution Using $** on page IV-15 for additional examples using $.

Waves as Parameters in Macros

The only way to pass a wave to a macro is to pass the name of the wave in a string parameter. You then use the $ operator to convert the string into a wave reference. For example:

```
Macro PrintWaveStdDev(w)
   String w

   WaveStats/Q $w
   Print V_sdev
End

Make/O/N=100 test=gnoise(1)
Print NamedWaveStdDev("test")
```

The Missing Parameter Dialog

When a macro that is declared to take a set of input parameters is executed with some or all of the parameters missing, it displays a dialog in which the user can enter the missing values. For example:

```
Macro MacCalcDiag(x,y)
   Variable x=10
   Prompt x, "Enter X component: "     // Set prompt for y param
   Variable y=20
   Prompt y, "Enter Y component: "     // Set prompt for x param

   Print "diagonal=",sqrt(x^2+y^2)
End
```

If invoked from the command line or from another macro with parameters missing, like this:

```
   MacCalcDiag()
```

Igor displays the Missing Parameter dialog in which the parameter values can be specified.

The Prompt statements are optional. If they are omitted, the variable name is used as the prompt text.

There must be a blank line after the set of input parameter and prompt declarations and there must not be any blank lines within the set.

The missing parameter dialog supports the creation of pop-up menus as described under **Pop-Up Menus in Simple Dialogs** on page IV-123. One difference is that in a missing parameter dialog, the menu item list can be continued using as many lines as you need. For example:

```
Prompt color, "Select Color", popup "red;green;blue;"
"yellow;purple"
```

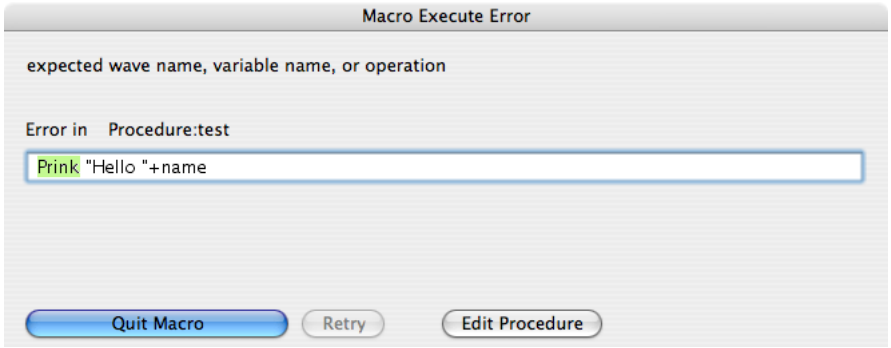
Macro Errors

Igor can find errors in macros at two times:

- When it scans the macros
- When it executes the macros

After you modify procedure text, scanning occurs when you activate a nonprocedure window, click the Compile button or choose Compile from the Macros menu. At this point, Igor is just looking for the names of procedures. The only errors that it detects are name conflicts and ill-formed names. If it finds such an error, it displays a dialog that you use to fix it.

Igor detects other errors when the macro executes. Execution errors may be recoverable or nonrecoverable. If a recoverable error occurs, Igor puts up a dialog in which you can edit the erroneous line.



You can fix the error and retry or quit macro execution.

If the error is nonrecoverable, you get a similar dialog except that you can't fix the error and retry. This happens with errors in the parameter declarations and errors related to if-else-endif and do-while structures.

The Silent Option

Normally Igor displays each line of a macro in the command line as it executes the line. This gives you some idea of what is going on. However it also slows macro execution down considerably. You can prevent Igor from showing macro lines as they are executed by using the `Silent 1` command.

You can use `Silent 1` from the command line. It is more common to use it from within a macro. The effect of the `Silent` command ends at the end of the macro in which it occurs. Many macros contain the following line:

```
Silent 1; PauseUpdate
```

The Slow Option

You can observe the lines in a macro as they execute in the command line. However, for debugging purposes, they often whiz by too quickly. The `Slow` operation slows the lines down. It takes a parameter which controls how much the lines are slowed down. Typically, you would execute something like "`Slow 10`" from the command line and then "`Slow 0`" when you are finished debugging.

You can also use the `Slow` operation from within a macro. You must explicitly invoke "`Slow 0`" to revert to normal behavior. It does not automatically revert at the end of the macro from which it was invoked.

We never use this feature. Instead, we generally use print statements for debugging or we use the Igor symbolic debugger, described in Chapter IV-8, **Debugging**.

Accessing Variables Used by Igor Operations

A number of Igor's operations return results via variables. For example, the WaveStats operation creates a number of variables with names such as V_avg, V_sigma, etc.

When you invoke these operations from the command line, they create global variables in the current data folder.

When you invoke them from a user-defined function, they create local variables.

When you invoke them from a macro, they create local variables unless a global variable already exists. If both a global variable and a local variable exist, Igor uses the local variable.

In addition to creating variables, a few operations, such as CurveFit and FuncFit, check for the existence of specific variables to provide optional behavior. The operations look first for a local variable with a specific name. If the local variable is not found, they then look for a global variable.

Updates During Macro Execution

An update is an action that Igor performs. It consists of:

- Reexecuting assignments for dependent objects whose antecedents have changed (see Chapter IV-9, **Dependencies**);
- Redrawing graphs and tables which display waves that have changed;
- Redrawing page layouts containing graphs, tables, or annotations that have changed;
- Redrawing windows that have been uncovered.

When no procedure is executing, Igor continually checks whether an update is needed and does an update if necessary.

During macro execution, Igor checks if an update is needed after executing each line. You can suspend checking using the PauseUpdate operation. This is useful when you want an update to occur when a macro finishes but not during the course of the macro's execution.

PauseUpdate has effect only inside a macro. Here is how it is used.

```
Window Graph0() : Graph
   PauseUpdate; Silent 1
   Display /W=(5,42,400,250) w0,w1,w2
   ModifyGraph gFont="Helvetica"
   ModifyGraph rgb(w0)=(0,0,0),rgb(w1)=(0,65535,0),rgb(w2)=(0,0,0)
   <more modifies here...>
End
```

Without the PauseUpdate, Igor would do an update after each modify operation. This would take a long time.

At the end of the macro, Igor automatically reverts the state of update-checking to what it was when this macro was invoked. You can use the ResumeUpdate operation if you want to resume updates before the macro ends or you can call DoUpdate to force an update to occur at a particular point in the program flow. Such explicit updating is rarely needed.

Aborting Macros

There are two ways to prematurely stop macro execution: a user abort or a programmed abort. Both stop execution of all macros, no matter how deeply nested.

On Macintosh, you can abort macro execution by pressing Command-period. On Windows, press Ctrl+Break or click the Abort button in the status bar. You may need to hold the keys down for a while because Igor looks at the keyboard periodically and if you don't press the keys long enough, Igor will not see them.

On either platform, you can abort macro execution by choosing Abort Procedure Execution from the Macros menu.

A user abort does not directly return. What it does is set a flag that stops loops from looping and then returns using the normal calling chain. For this reason some code will still be executed after an abort but execution should stop quickly. This behavior releases any temporary memory allocations made during execution.

A **programmed abort** occurs when the Abort operation is executed. Here is an example:

```
if( numCells > 10 )
   Abort "Too many cells! Quitting."
endif
// code here doesn't execute if numCells > 10
```

Converting Macros to Functions

If you have old Igor procedures written as macros, as you have occasion to revisit them, you can consider converting them to functions. In most cases, this is a good idea. An exception is if the macros are so complex that there would be a substantial risk of introducing bugs. In this case, it is better to leave things as they are.

If you decide to do the conversion, here is a checklist that you can use in the process.

1. Back up the old version of the procedures.
2. Change the defining keyword from Macro or Proc to Function.
3. If the macro contained Prompt statements, then it was used to generate a missing parameter dialog. Change it to generate a simple input dialog as follows:
   a. Remove the parameters from the parameter list. The old parameter declarations now become local variable declarations.
   b. Make sure that the local variable for each prompt statement is initialized to some value.
   c. Add a DoPrompt statement after all of the Prompt statements.
   d. Add a test on V_Flag after the DoPrompt statement to see if the user canceled.
4. Look for statements that access global variables or strings and create NVAR and SVAR references for them.
5. Look for any waves used in assignment statements and create WAVE references for them.
6. Compile procedures. If you get an error, fix it and repeat step 6.

Chapter
IV-5

User-Defined Menus

Overview

You can add your own menu items to many Igor menus by writing a menu definition in a procedure window. A simple menu definition looks like this:

```
Menu "Macros"
   "Load Data File/1"
   "Do Analysis/2"
   "Print Report"
End
```

This adds three items to the Macros menu. If you choose Load Data File or press Command-1 (*Macintosh*) or Ctrl+1 (*Windows*), Igor will execute the procedure LoadDataFile which, presumably, you have written in a procedure window. The command executed when you select a particular item is derived from the text of the item. This is an *implicit* specification of the item's execution text.

You can also *explicitly* specify the execution text:

```
Menu "Macros"
   "Load Data File/1", Beep; LoadWave/G
   "Do Analysis/2"
   "Print Report"
End
```

Now if you choose Load Data File, Igor will execute "`Beep; LoadWave/G`".

When you choose a user menu item, Igor checks to see if there is execution text for that item. If there is, Igor executes it. If not, Igor makes a procedure name from the menu item string. It does this by removing any characters that are not legal characters in a procedure name. Then it executes the procedure. For example, choosing an item that says

```
"Set Sampling Rate..."
```

executes the SetSamplingRate procedure.

If a procedure window is the top window and if Option (*Macintosh*) or Alt (*Windows*) is pressed when you choose a menu item, Igor tries to find the procedure in the window, rather than executing it.

A menu definition can add submenus as well as regular menu items.

```
Menu "Macros"
   Submenu "Load Data File"
      "Text File"
      "Binary File"
   End

   Submenu "Do Analysis"
      "Method A"
      "Method B"
   End

   "Print Report"
End
```

This adds three items to the Macros menu, two submenus and one regular item. You can nest submenus to any depth.

There are some limits to the number of menu items that you can add. Igor can handle no more than 100 user-defined main menus and not more than 300 user-defined submenus.

The user-defined menus added by procedure files opened in the current experiment (such as the Example Experiments menu item in the File menu added by the WMMenus.ipf procedure file in "Igor Pro Folder/Igor Procedures") count against those limits.

In the Windows version of Igor, there is also a limit of 31 items in a menu, and each special user-defined menu counts as several user-defined menus or submenus. For example, a "*COLORPOP*" submenu counts as 6 submenus against the allowed 200. See **Specialized Menu Item Definitions** on page IV-112.

Menu Definition Syntax

The syntax for a menu definition is:

```
Menu <Menu title string> [,<menu options>]
   [<Menu help strings>]
   <Menu item string> [,<menu item flags>] [,<execution text>]
   [<Item help strings>]
   …
   Submenu <Submenu title string>
      [<Submenu help strings>]
      <Submenu item string> [,<execution text>]
      [<Item help strings>]
      …
   End
End
```

<Menu title string> is the title of the menu to which you want to add items. Often this will be Macros but you can also add items to Analysis, Misc and many other built-in Igor menus, including some submenus and the graph marquee and layout marquee menus. If <Menu title string> is not the title of a built-in menu then Igor creates a new main menu on the menu bar.

<Menu options> are optional comma-separated keywords that change the behavior of the menu. The allowed keywords are dynamic, hideable, and contextualmenu. For usage, see **Dynamic Menu Items** (see page IV-109), **HideIgorMenus** (see page V-242), and **PopupContextualMenu** (see page V-487) respectively.

<Menu help strings> specifies the help for the menu title. This is optional. See **Help for User Menus** on page IV-108 for details.

<Menu item string> is the text to appear for a single menu item, a semicolon-separated string list to define **Multiple Menu Items** (see page IV-111), or **Specialized Menu Item Definitions** (see page IV-112) such as a color, line style, or font menu.

<Menu item flags> are optional flags that modify the behavior of the menu item. The only flag currently supported is /Q, which prevents Igor from storing the executed command in the history area. This is useful for menu commands that are executed over and over through a keyboard shortcut. This feature was introduced in Igor Pro 5. Using it will cause errors in earlier versions of Igor. Menus defined with the contextualmenu keyword implicitly set all the menu item flags in the entire menu to /Q; it doesn't matter whether /Q is explicitly set or not, the executed command is not stored in the history area.

<Execution text> is an Igor command to execute for the menu item. If omitted, Igor makes a procedure name from the menu item string and executes that procedure. Use "" to prevent command execution (useful only with PopupContextualMenu/N).

<Item help strings> specifies the help for the menu item. This is optional. It can appear after a main menu item or after a submenu item. See **Help for User Menus** on page IV-108 for details.

The Submenu keyword introduces a submenu with <Submenu title string> as its title. The submenu continues until the next End keyword.

<Submenu item string> acts just like <Menu item string>.

Built-in Menus That Can Be Extended

Here are the titles of built-in Igor menus to which you can add items.

Add Controls	AllTracesPopup	Analysis	Append to Graph	Control
Data	Edit	File	Graph	GraphMarquee
Help	Layout	LayoutMarquee	Load Waves	Macros
Misc	Statistics	New	Notebook	Open File
Panel	Procedure	Save Waves	Table	TracePopup

These menu titles must appear in double quotes when used in a menu definition.

Use these menu titles to identify the menu to which you want to append items even if you are working with a version of Igor translated into a language other than English.

The GraphMarquee, LayoutMarquee, TracePopup, and AllTracesPopup menus are contextual menus. See **Marquee Menus** on page IV-119 and **Trace Menus** on page IV-119.

All other Igor menus, including menus added by XOPs, can not accept user-defined items.

The **HideIgorMenus** operation (see page V-242) and the **ShowIgorMenus** operation (see page V-571) hide or show most of the built-in main menus (not the Marquee and Popup menus). User-defined menus that add items to built-in menus are normally not hidden or shown by these operations. When a built-in menu is hidden, the user-defined menu items create a user-defined menu with only user-defined items. For example, this user-defined menu:

```
Menu "Table"
   "Append Columns to Table...", DoIgorMenu "Table", "Append Columns to Table"
End
```

will create a Table menu with only one item in it after the HideIgorMenus "Table" command is executed.

To have your user-defined menu items hidden along with the built-in menu items, add the hideable keyword after the Menu definition:

```
Menu "Table", hideable
   "Append Columns to Table...", DoIgorMenu "Table", "Append Columns to Table"
End
```

Adding a New Main Menu

You can add an entirely new menu to the main menu bar by using a menu title that is not used by Igor. For example:

```
Menu "Test"
   "Load Data File"
   "Do Analysis"
   "Print Report"
End
```

Help for User Menus

You can specify help for the menus and menu items that you define. On Mac OS X, the help text appears if you enable Igor Tips through the Help menu. On Windows, Igor uses the help text to provide status line help.

```
Menu "Test"
   help = {"This is the help for the Test menu."}

   "Load Data File"
   help = {"This is the help for the Load Data File item."}

   "Do Analysis"
   help = {"This is the help for the Do Analysis item."}
```

```
   "Print Report"
   help = {"This is the help for the Print Report item."}
End
```

The first help line specifies the help text for the menu title. The subsequent lines specify the help text to appear for the respective menu items.

On Macintosh, help does not appear for menu and submenu titles. It does appear over menu and submenu items.

Because of technical difficulties, help for user-defined items in the Edit menu will not appear. Also, on Macintosh, help for user-defined items in the Help menu will not appear.

The full form of the menu help specification is:

```
help = {"String 1", "String 2", "String 3", "String 4"}
```

String 1 supplies the text to appear when the menu or menu item is enabled. String 2 supplies the text to appear when the menu or menu item is disabled. String 3 supplies the text to appear when the menu or menu item is checked. String 4 supplies the text to appear when the menu or menu item is marked with a marker other than check.

If you omit one or more of these strings, Igor uses the text for string 1 for the corresponding state. Thus, the following are equivalent:

```
help = {"Test 1", "Test 2", "Test 1", "Test 1"}
help = {"Test 1", "Test 2"}
```

In most cases, it will be sufficient to provide just the text for the enabled state since you will most likely not go to the trouble of enabling, disabling or checking your menu items.

Dynamic Menu Items

In the examples shown so far all of the user-defined menu items are static. Once defined, they never change. This is sufficient for the vast majority of cases and is by far the easiest way to define menu items.

Igor also provides support for dynamic user-defined menu items. A dynamic menu item changes depending on circumstances. The item might be enabled under some circumstances and disabled under others. It might be checked or deselected. Its text may toggle between two states (e.g. “Show Tools” and “Hide Tools”).

Because dynamic menus are much more difficult to program than static menus and also slow down Igor’s response to a menu-click, we recommend that you keep your use of dynamic menus to a minimum. The effort you expend to make your menu items dynamic may not be worth the time you spend to do it.

For a menu item to be dynamic, you must define it using a string expression instead of the literal strings used so far. Here is an example.

```
Function DoAnalysis()
   Print "Analysis Done"
End

Function ToggleTurboMode()
   Variable prevMode = NumVarOrDefault("root:gTurboMode", 0)
   Variable/G root:gTurboMode = !prevMode
End

Function/S MacrosMenuItem(itemNumber)
   Variable itemNumber

   Variable turbo = NumVarOrDefault("root:gTurboMode", 0)

   if (itemNumber == 1)
      if (strlen(WaveList("*", ";", ""))==0) // any waves exist?
```

```
         return "(Do Analysis"   // disabled state
      else
         return "Do Analysis"    // enabled state
      endif
   endif

   if (itemNumber == 2)
      if (turbo)
         return "!"+num2char(18)+"Turbo"  // Turbo with a check
      else
         return "Turbo"
      endif
   endif
End

Menu "Macros", dynamic
   MacrosMenuItem(1)
   help= {"Do analysis", "Not available because there are no waves."}

   MacrosMenuItem(2), /Q, ToggleTurboMode()
   help= {"When checked, turbo mode is on."}
End
```

In this example, the text for the menu item is computed by the MacrosMenuItem function. It computes text for item 1 and for item 2 of the menu. Item 1 can be enabled or disabled. Item 2 can be checked or unchecked.

The dynamic keyword specifies that the menu definition contains a string expression that needs to be reevaluated each time the menu item is drawn. This rebuilds the user-defined menu each time the user clicks in the menu bar. Under the current implementation, *all* user menus are rebuilt each time the user clicks in the menu bar if *any* user-defined menu is declared dynamic. If you use a large number of user-defined items, the time to rebuild the menu items may be noticeable.

There is another technique for making menu items change. You define a menu item using a string expression rather than a literal string but you do not declare the menu dynamic. Instead, you call the BuildMenu operation whenever you need the menu item to be rebuilt. Here is an example:

```
Function ToggleItem1()
   String item1Str = StrVarOrDefault("root:MacrosItem1Str","On")
   if (CmpStr(item1Str,"On") == 0)     // Item is now "On"?
      String/G root:MacrosItem1Str = "Off"
   else
      String/G root:MacrosItem1Str = "On"
   endif
   BuildMenu "Macros"
End

Menu "Macros"
   StrVarOrDefault("root:MacrosItem1Str","On"), /Q, ToggleItem1()
End
```

Here, the menu item is controlled by the global string variable MacrosItem1Str. When the user chooses the menu item, the ToggleItem1 function runs. This function changes the MacrosItem1Str string and then calls BuildMenu, which rebuilds the user-defined menu the next time the user clicks in the menu bar. Under the current implementation, Igor will rebuild *all* user-defined menus if BuildMenu is called for *any* user-defined menu.

Optional Menu Items

A dynamic user-defined menu item *disappears* from the menu if the menu item string expression evaluates to ""; the remainder of the menu definition line is then ignored. This makes possible a variable number of items in a user-defined menu list. This example adds a menu listing the names of up to 8 waves in the current data folder. If the current data folder contains less than 8 waves, then only those that exist are shown in the menu:

```
Menu "Waves", dynamic
   WaveName("",0,4), DoSomething($WaveName("",0,4))
   WaveName("",1,4), DoSomething($WaveName("",1,4))
   WaveName("",2,4), DoSomething($WaveName("",2,4))
   WaveName("",3,4), DoSomething($WaveName("",3,4))
   WaveName("",4,4), DoSomething($WaveName("",4,4))
   WaveName("",5,4), DoSomething($WaveName("",5,4))
   WaveName("",6,4), DoSomething($WaveName("",6,4))
   WaveName("",7,4), DoSomething($WaveName("",7,4))
End

Function DoSomething(w)
   Wave/Z w

   if( WaveExists(w) )
      Print "DoSomething: wave's name is "+NameOfWave(w)
   endif
End
```

This works because WaveName returns "" if the indexed wave doesn't exist.

Note that each potential item must have a menu definition line that either appears or disappears.

Multiple Menu Items

A menu item string that contains a semicolon-separated "string list" (see **StringFromList** on page V-675) generates a menu item for each item in the list. For example:

```
Menu "Multi-Menu"
   "first item;second item;", DoItem()
End
```

Multi-Menu will be a two-item menu. When either item is selected the DoItem procedure is called.

This begs the question: How does the DoItem procedure know which item was selected? The answer is that DoItem must call the **GetLastUserMenuInfo** operation (see page V-216) and examine the appropriate returned variables, usually V_value (the selected item's number, 1 for the first item, 2 for the second, etc.) or S_Value (the selected item's text).

The string list can be dynamic, too. The above "Waves" example can be rewritten to handle an arbitrary number of waves (maximum 31 on Windows) using this definition:

```
Menu "Waves", dynamic
   WaveList("*",";",""), DoItem()
End

Function DoItem()
   GetLastUserMenuInfo           // sets S_value, V_value, etc.
   WAVE/Z w= $S_value
   if( WaveExists(w) )
      Print "The wave's name is "+NameOfWave(w)
   endif
End
```

Consolidating Menu Items Into a Submenu

It is common to have many utility procedure files open at the same time. Each procedure file could add menu items which would clutter Igor's menus. When you create a utility procedure file that adds multiple menu items, it is usually a good idea to consolidate all of the menu items into one submenu. Here is an example.

Let's say we have a procedure file full of utilities for doing frequency-domain data analysis and that it contains the following:

```
Function ParzenDialog()
   …
End

Function WelchDialog()
   …
End

Function KaiserDialog()
   …
End
```

We can consolidate all of the menu items into a single submenu in the Analysis menu:

```
Menu "Analysis"
   Submenu "Windows"
      "Parzen…", ParzenDialog()
      "Welch…", WelchDialog()
      "Kaiser…", KaiserDialog()
   End
End
```

Specialized Menu Item Definitions

A menu item string that contains certain special values adds a specialized menu such as a color menu.

Only one specialized menu item string is allowed in each menu or submenu, it must be the first item, and it must be the only item.

Menu Item String	Result
"*CHARACTER*	"Character menu, no character is initially selected, font is Geneva, font size is 12. See **Menu Limits** on page IV-113 for *CHARACTER* menu limitations.
"*CHARACTER*(Symbol)	"Character menu of Symbol font.
"*CHARACTER*(Symbol,36)	"Character menu of Symbol font in 36 point size.
"*CHARACTER*(,36)	"Character menu of Geneva font in 36 point size.
"*CHARACTER*(Symbol,36,p)	"Character menu of Symbol font in 36 point size, initial character is p (π).
"*COLORTABLEPOP*	"Color table menu, initial table is Grays.
"*COLORTABLEPOP*(YellowHot)	"Color table menu, initial table is YellowHot. See **CTabList** on page V-81 for a list of color tables.
"*COLORTABLEPOP*(YellowHot,1)	"Color table menu with the colors drawn reversed.
"*COLORPOP*	"Color menu, initial color is black.
"*COLORPOP*(0,65535,0)	"Color menu, initial color is green.
"*FONT*	"Font menu, no font is initially selected, does not include "default" as a font choice. See **Menu Limits** on page IV-113 for *FONT* menu limitations.
"*FONT*(Arial)	"Font menu, Arial is initially selected.
"*FONT*(Arial,default)	"Font menu with Arial initially selected and including "default" as a font choice.
"*LINESTYLEPOP*	"Line style menu, no line style is initially selected.

Menu Item String	Result
"*LINESTYLEPOP*(3)	"Line style menu, initial line style is style=3 (coarse dashed line).
"*MARKERPOP*	"Marker menu, no marker is initially selected.
"*MARKERPOP*(8)	"Marker menu, initial marker is 8 (empty circle).
"*PATTERNPOP*	"Pattern menu, no pattern is initially selected.
"*PATTERNPOP*(1)	"Pattern menu, initial pattern is 1 (SW-NE light diagonal).

To retrieve the selected color, line style, etc., the execution text must be a procedure that calls the **GetLastUserMenuInfo** operation (see page V-216). Here's an example of a color submenu implementation:

```
Menu "Main", dynamic
   "First Item", /Q, HandleFirstItem()
   Submenu "Color"
      CurrentColor(), /Q, SetSelectedColor() // must be first item
                                             // can't add items here
   End
   "Third Item", /Q, HandleThirdItem()
End

Function/S CurrentColor()
   Variable/G root:red, root:green, root:blue
   NVAR red= root:red
   NVAR green= root:green
   NVAR blue= root:blue
   String menuText
   sprintf menuText, "*COLORPOP*(%d,%d,%d)", red, green, blue
   return menuText
End

Function SetSelectedColor()
   GetLastUserMenuInfo  // sets V_red, V_green, V_blue, S_value, V_value
   Variable/G root:red= V_red
   Variable/G root:green= V_green
   Variable/G root:blue= V_blue

   Make/O/N=(2,2,3) root:colorSpot
   Wave colorSpot= root:colorSpot
   colorSpot[][][0]= V_red
   colorSpot[][][1]= V_green
   colorSpot[][][2]= V_blue

   CheckDisplayed/A colorSpot
   if( V_Flag == 0 )
      NewImage colorSpot
   endif
End
```

Menu Limits

Although the maximum font size allowed is 99, the *CHARACTER* menus are limited to about 800 pixels wide by 600 pixels high and most font sizes above 48 or so don't increase the font size of the displayed characters.

The *FONT* menus are quite different on Macintosh and Windows.

The Macintosh menu is just a long menu of all the fonts, optionally with "default" at the bottom.

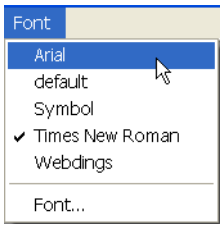
On Windows, menus are limited to 31 items. If you specify just "*FONT*", the resulting menu item has just a "Font…" item. You can list up to 28 font names including the initially-selected font (the first one listed) and optionally a divider represented by "-". "default" can be one of the listed font names. A "Font…" item

always appears in the menu to select any installed font. Fonts that you list but which are not installed are ignored and won't appear in the menu. Those that do appear are sorted alphabetically. For example:

```
Menu " Font"        // (The "Font" menu is restricted, but " Font" isn't)
    "*FONT*(Times New Roman,default,Arial,Webdings,Symbol)", DoFont()
End

Function DoFont()
    GetLastUserMenuInfo
    Print S_value
End
```

produces a Font menu with "Orange LET" initially selected and all the listed fonts as (sorted) font choices:



On Windows, most specialized menu items count as more than one menu against the limits of 100 user-defined main menus or 200 user-defined submenus:

Menu Kind	Effective Number of Menus (Windows only)
"*FONT*"	1
"*LINESTYLEPOP"*	1
"*PATTERNPOP*"	3
"*MARKERPOP*"	2
"*CHARACTER*"	8
"*COLORPOP*"	6
"*COLORTABLEPOP*"	2

Special Characters in Menu Item Strings

You can control some aspects of a menu item by using special characters. These special characters are based on the behavior of the Macintosh menu manager and are only partially supported on Windows (see **Special Menu Characters on Windows** on page IV-116). They affect user-defined menus in the main menu bar. On Macintosh, but not on Windows, they also affect user-defined pop-up menus in control panels, graphs and simple input dialogs.

By default, special character interpretation is enabled in user-defined menu bar menus and is disabled in user-defined control panel, graph and simple input dialog pop-up menus. This is almost always what you would want. In some cases, you might want to override the default behavior. This is discussed under **Enabling and Disabling Special Character Interpretation** on page IV-116.

This table shows the special characters and their effect if special character interpretation is enabled. See **Special Menu Characters on Windows** on page IV-116 for Windows-specific considerations.

Character	Behavior
/	Creates a keyboard shortcut for the menu item. The character after the slash defines the item's keyboard shortcut. For example, `"Low Pass/1"` makes the item "Low Pass" with a keyboard shortcut for Command-1 (*Macintosh*) or Ctrl-1 (*Windows*). You can also use function keys. To avoid conflicts with Igor, use the numeric keys and the function keys only. See **Keyboard Shortcuts** on page IV-118 and **Function Keys** on page IV-118 for further details. Keyboard shortcuts are not supported in the graph marquee and layout marquee menus.
-	Creates a divider between menu items. If a hyphen (minus sign) is the first character in the item then the item will be a disabled divider. This can be a problem when trying to put negative numbers in a menu. Use a leading space character to prevent this. The string "(-" also disables the corresponding divider.
(	Disables the menu item. If a left parenthesis appears anywhere in the item then the item will be disabled.
!	Adds a mark to the menu item. If an exclamation point appears in the item, the character after the exclamation point will appear to the left of the menu item. For example, "Low Pass!*" makes an item "Low Pass" with an asterisk to the left. To mark an item with a check, use `"Low Pass!" + num2char(18)` This is necessary because the character code (18) for a check mark is a nonprinting control character that is not displayed correctly in most fonts.
<	Controls the typographic style of the item. This is rarely used since it tends to make the menu too garish.
^	Draws an icon as the menu item. This is not supported in Igor. Do not use it.
;	Separates one menu item from the next. Example: `"Item 1;Item 2"`

Whereas it is standard practice to use a semicolon to separate items in a pop-up menu in a control panel, graph or simple input dialog, you should avoid using the semicolon in user-defined main-menu-bar menus. It is clearer if you use one item per line. It is also necessary in some cases (see **Menu Definition Syntax** on page IV-107).

If a left angle bracket appears in the item, then the style of type for the item is controlled by the character following the angle bracket as follows:

Character Sequence	Makes Item
<B	bold
<I	italic
<U	underlined
<O	outlined
<S	shadowed

For example, "Low Pass<U" makes the item "Low Pass" with an underline.

If special character interpretation is disabled, these characters will appear in the menu item instead of having their special effect. The semicolon character is treated as a separator of menu items even if special character interpretation is disabled.

Special Menu Characters on Windows

On Windows, these characters are treated as special in menu bar menus but not in pop-up menus in graphs, control panels, and simple input dialogs. The following table shows which special characters are supported.

Character	Meaning	Status
/	Defines accelerator	Supported
-	Divider	Supported
(	Disables item	Supported
!	Adds mark to item	Partially supported — see discussion below
<	Controls typography	Not supported — ignored
^	Specifies icon	Not supported — ignored
;	Separates items	Supported

Windows does not directly support marking a menu item with anything other than a checkmark. Therefore, on Windows, when Igor sees the "!" special character, it checks the menu item regardless of which character follows the "!". The following user-defined menu item definition will produce a checked item on both platforms:

```
"Test!" + num2char(18)
```

"`num2char(18)`" returns the character code for a check mark on the Macintosh.

In general, Windows does not allow using Ctrl+<punctuation> as an accelerator. Therefore, in the following example, the accelerator will not do anything:

```
Menu "Macros"
   "Test/["       // "/[" will not work on Windows.
End
```

On Windows, you can designate a character in a menu item as a mnemonic keystroke by preceding the character with an ampersand:

```
Menu "Macros"
   "&Test", Print "This is a test"
End
```

This designates "T" as the mnemonic keystroke for Test. To invoke this menu item, press Alt and release it, press the "M" key to highlight the Macros menu, and press the "T" key to invoke the Test item. If you hold the Alt key pressed while pressing the "M" and "T" keys and if the active window is a procedure window, Igor will not execute the item's command but rather will bring up the procedure window and display the menu definition. This is a programmer's shortcut.

Note: The mnemonic keystroke is not supported on Macintosh. If you use an ampersand in a menu item, it will appear in the menu item on the Macintosh. For this reason, if you care about cross-platform compatibility, you should not use ampersands in your menu items.

Enabling and Disabling Special Character Interpretation

The interpretation of special characters in menu items can sometimes get in the way. For example, you may want a menu item to say "m/s" or "A<B". With special character interpretation enabled, the first of these would become "m" with "s" as the keyboard shortcut and the second would become "A" in a bold typeface.

Igor provides WaveMetrics-defined escape sequences that allow you to override the default state of special character interpretation. These escape sequences are case sensitive and must appear at the very start of the menu item:

Escape Code	Effect	Example	
"\\M0"	Turns special character interpretation off.	"\\M0m/s"	"\\M1"	Turns special character interpretation on.	"\\M1m/s"	

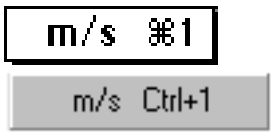
The most common use for this will be in a user-defined menu bar menu in which the default state is on and you want to display a special character in the menu item text itself. That is what you can do with the "\\M0" escape sequence.

Another possible use on Macintosh is to create a disabled menu item in a control panel, graph or simple input dialog pop-up menu. The default state of special character interpretation in pop-up menus is off. To disable the item, you either need to turn it on, using "\\M1" or to use the technique described in the next paragraph.

What if we want to include a special character in the menu item itself *and* have a keyboard shortcut for that item? The first desire requires that we turn special character interpretation off and the second requires that we turn it on. The WaveMetrics-defined escape sequence can be extended to handle this. For example:

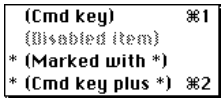
```
"\\M0:/1:m/s"
```



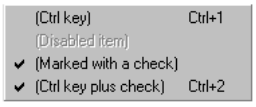
The initial "\\M0" turns normal special character interpretation off. The first colon specifies that one or more special characters are coming. The /1 makes Command-1 (*Macintosh*) or Ctrl+1 (*Windows*) the keyboard shortcut for this item. The second colon marks the end of the menu commands and starts the regular menu text which is displayed in the menu without special character interpretation. The final result is as shown above.

Any of the special characters can appear between the first colon and the second. For example:

```
Menu "Macros"
   "\\M0:/1:(Cmd key)"
   "\\M0:(:(Disabled item)"
   "\\M0:!*:(Marked with *)"
   "\\M0:/2!*:(Cmd key plus *)"
End
```



```
Menu "Macros"
   "\\M0:/1:(Ctrl key)"
   "\\M0:(:(Disabled item)"
   "\\M0:!"+num2char(18)+":(Marked with a check)"
   "\\M0:/2!"+num2char(18)+":(Ctrl key plus check)"
End
```



The \\M escape code affects just the menu item currently being defined. In the following example, special character interpretation is enabled for the first item but not for the second:

```
"\\M1(First item;(Second item"
```

To enable special character interpretation for both items, we need to write:

```
"\\M1(First item;\\M1(Second item"
```

Keyboard Shortcuts

A keyboard shortcut is a set of one or more keys which invoke a menu item. In a menu item string, a keyboard shortcut is introduced by the / special character. For example:

```
Menu "Macros"
   "Test/1"       // The keyboard shortcut is Cmd-1 (Macintosh)
End               // or Ctrl-1 (Windows).
```

All of the alphabetic keyboard shortcuts (/A…/Z) are used by Igor. Numeric keyboard shortcuts (/0…/9) are available for use in user menu definitions as are Function Keys, described below.

You can define a numeric keyboard shortcut that includes one or more modifier keys. The modifier keys are Shift and Option (*Macintosh*) or Alt (*Windows*). For example:

```
Menu "Macros"
   "Test/1"       // Cmd-1, Ctrl-1
   "Test/S1"      // Shift-Cmd-1, Ctrl-Shift-1.
   "Test/O1"      // Option-Cmd-1, Ctrl-Alt-1
   "Test/OS1"     // Option-Shift-Cmd-1, Ctrl-Shift-Alt-1
End
```

On Macintosh, “L” can be used to indicated that the Control key must be pressed. This is not supported on Windows.

Function Keys

Most keyboards have function keys labeled F1 through F12. In Igor, you can treat a function key as a keyboard shortcut that invokes a menu item.

Note: Mac OS X reserves nearly all function keys for itself. In order to use function keys for an application, you must check a checkbox in the Keyboard control panel. Even then the OS will intercept some function keys.

Note: On Windows, Igor uses F1 for help-related operations. F1 will not work as a keyboard shortcut on Windows. Also, the Windows OS reserves Ctrl-F4 and Ctrl-F6 for closing and reordering windows.

Here is a simple function key example:

```
Menu "Macros"
   "Test/F5"      // The keyboard shortcut is F5.
End
```

As with other keyboard shortcuts, you can specify that one or more modifier keys must be pressed along with the function key. The modifier keys are Shift and Option (*Macintosh*) or Alt (*Windows*).

```
Menu "Macros"
   // Function keys with and without modifiers
   "Test/F5"      // F5
   "Test/SF5"     // Shift-F5
   "Test/OF5"     // Option-F5, Alt-F5
   "Test/SOF5"    // Shift-Option-F5, Shift-Alt-F5
End
```

By including the “C” modifier character, you specify that the Command (*Macintosh*) or Ctrl (*Windows*) key must also be pressed:

```
Menu "Macros"
   // Cmd-Function or Ctrl-Function keys with and without modifiers
   "Test/CF5"     // Cmd-F5, Ctrl-F5
   "Test/SCF5"    // Shift-Cmd-F5, Ctrl-Shift-F5
   "Test/OCF5"    // Option-Cmd-F5, Ctrl-Alt-F5
   "Test/OSCF5"   // Option-Shift-Cmd-F5, Ctrl-Shift-Alt-F5
End
```

On Macintosh only, you can also use Control as a modifier by adding an “L” between the slash and the “F5”.

Although some keyboards have function keys labeled F13 and higher, they do not behave consistently and are not supported.

Marquee Menus

Igor has two menus called "marquee menus". In graphs and page layouts you create a marquee when you drag diagonally. Igor displays a dashed-line box indicating the area of the graph or layout that you have selected. If you click inside the marquee, you get a marquee menu.

You can add your own menu items to a marquee menu by creating a GraphMarquee or LayoutMarquee menu definition. For example:

```
Menu "GraphMarquee"
   "Print Marquee Coordinates", GetMarquee bottom; Print V_left, V_right
End
```

The use of keyboard shortcuts is not supported in marquee menus.

See **Marquee Menu as Input Device** on page IV-140 for details.

Trace Menus

Igor has two "trace" menus named "TracePopup" and "AllTracesPopup". When you control-click or right-click in a graph on a trace you get the TracesPopupMenu. If you hold down Shift while clicking, you get the AllTracesPopup (standard menu items in that menu operated on all the traces in the graph). You can append menu items to these menus with Menu "TracePopup" and Menu "AllTracesPopup" definitions.

For example:

```
Menu "TracePopup"
   "IdentifyTrace", /Q, IdentifyTrace()
End

Function IdentifyTrace()
   GetLastUserMenuInfo
   Print S_graphName, S_traceName
End
```

Popup Contextual Menus

You can create a custom pop-up contextual menu to respond to a control-click or right-click. For an example, see **Creating a Contextual Menu** on page IV-139.

Chapter
IV-6

Interacting with the User

Overview

The following sections describe the various programming techniques available for getting input from and for interacting with a user during the execution of your procedures. These techniques include:

- The simple input dialog
- Control panels
- Cursors
- Marquee menus

The simple input dialog provides a bare bones but functional user interfaces with just a little programming. In situations where more elegance is required, control panels provide a better solution.

Modal and Modeless User Interface Techniques

Before the rise of the graphical user interface, computer programs worked something like this: The user would start the program which would then ask the user for input. The program would then do some processing, after which it would ask the user for more input. In this model, the program is in charge and the user must respond with specific input at specific points of program execution. This is called a "modal" user interface because the program has one mode in which it will only accept specific input and another mode in which it will only do processing.

The Macintosh changed all this with the idea of event-driven programming. In this model, the computer waits for an event such as a mouse click or a key press and then acts on that event. The user is in charge and the program responds. This is called a "modeless" user interface because the program will accept any user action at any time.

You can use both techniques in Igor. Your program can put up a modal dialog asking for input and then do its processing or you can use control panels to build a sophisticated modeless event-driven system.

Event-driven programming is quite a bit more work than dialog-driven programming. You have to be able to handle user actions in any order rather than progressing through a predefined sequence of steps. In real life, a combination of these two methods is often used.

The Simple Input Dialog

The simple input dialog is a way by which a function can get input from the user in a modal fashion. It is very simple to program and is also somewhat simple in appearance.

A simple input dialog is presented to the user when a DoPrompt statement is executed in a function. Parameters to DoPrompt specify the title for the dialog and a list of local variables. For each variable, you must include a Prompt statement that provides the text label for the variable.

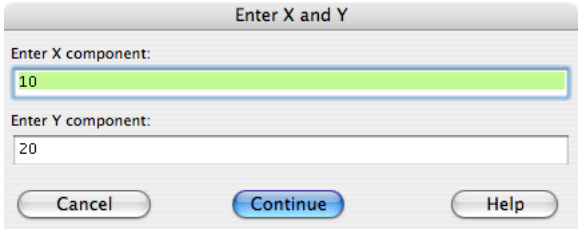
Generally, the simple input dialog is used in conjunction with routines that run when the user chooses an item from a menu. This is illustrated in the following example which you can type into the procedure window of a new experiment:

```
Menu "Macros"
   "Calculate Diagonal...", CalcDiagDialog()
End

Function CalcDiagDialog()
   Variable x=10,y=20
   Prompt x, "Enter X component: "  // Set prompt for x param
   Prompt y, "Enter Y component: "  // Set prompt for y param
   DoPrompt "Enter X and Y", x, y
   if (V_Flag)
      return -1                     // User canceled
   endif
```

```
   Print "Diagonal=",sqrt(x^2+y^2)
End
```

If you run the CalcDiagDialog function, you will see the following dialog:



If the user presses Continue without changing the default values, "Diagonal= 22.3607" will be printed in the history. If the user presses Cancel, nothing will be printed because DoPrompt sets the V_Flag variable to 1 in this case.

The simple input dialog allows for up to 10 numeric or string variables. When more than 5 items are used, the dialog uses two columns and you may have to limit the length of your Prompt text.

The simple input dialog is unique in that you can enter not only literal numbers or strings but also numeric expressions or string expressions. Any literal strings that you enter must be quoted.

If the user presses the Help button, Igor will search for a help topic with a name derived from the dialog title. If such a help topic is not found, then generic help about the simple input dialog will be presented. In both cases, the input dialog will remain until the user presses either Continue or Cancel.

Pop-Up Menus in Simple Dialogs

The simple input dialog supports pop-up menus as well as text items. The pop-up menus can contain an arbitrary list of items such as a list of wave names. To use a pop-up menu in place of the normal text entry item in the dialog, you use the following syntax in the prompt declaration:

```
Prompt <variable name>, <title string>, popup <menu item list>
```

The popup keyword indicates that you want a pop-up menu instead of the normal text entry item. The menu list specifies the items in the pop-up menu separated by semicolons. For example:

```
Prompt color, "Select Color", popup "red;green;blue;"
```

If the menu item list is too long to fit on one line, you can compose the list in a string variable like so:

```
String stmp= "red;green;blue;"
stmp += "yellow;purple"
Prompt color, "Select Color", popup stmp
```

The pop-up menu items support the same special characters as the user-defined menu definition (see **Special Characters in Menu Item Strings** on page IV-114) except that items in pop-up menus are limited to 50 characters, keyboard shortcuts are not supported, and special characters are disabled by default.

You can use pop-up menus with both numeric and string parameters. When used with numeric parameters the number of the item chosen is placed in the variable. Numbering starts from one. When used with string parameters the text of the chosen item is placed in the string variable.

There are a number of functions, such as the **WaveList** function (see page V-725) and the **TraceNameList** function (see page V-710), that are useful in creating pop-up menus.

To obtain a menu item list of all waves in the current data folder, use:

```
WaveList("*", ";", "")
```

To obtain a menu item list of all waves in the current data folder whose names end in "_X", use:

```
WaveList("*_X", ";", "")
```

To obtain a menu item list of all traces in the top graph, use:

```
TraceNameList("", ";", 1)
```

For a list of all contours in the top graph, use ContourNameList. For a list of all images, use ImageNameList. For a list of waves in a table, use WaveList.

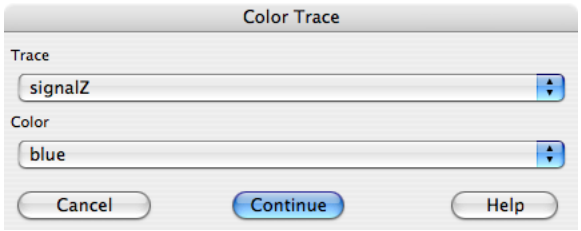
This next example creates two pop-up menus in the simple input dialog.

```
Menu "Macros"
   "Color Trace...", ColorTraceDialog()
End

Function ColorTraceDialog()
   String traceName
   Variable color=3
   Prompt traceName,"Trace",popup,TraceNameList("",";",1)
   Prompt color,"Color",popup,"red;green;blue"
   DoPrompt "Color Trace",traceName,color
   if( V_Flag )
      return 0          // user canceled
   endif

   if (color == 1)
      ModifyGraph rgb($traceName)=(65000, 0, 0)
   elseif(color == 2)
      ModifyGraph rgb($traceName)=(0, 65000, 0)
   elseif(color == 3)
      ModifyGraph rgb($traceName)=(0, 0, 65000)
   endif
End
```

If you choose Color Trace from the Macros menu, Igor brings up the simple input dialog with two pop-up menus. The first menu contains a list of all traces in the target window which is assumed to be a graph. The second menu contains the items red, green and blue with blue (item number 3) initially chosen.



After you choose the desired trace and color from the pop-up menus and click the Continue button, the function continues execution. The string parameter traceName will contain the name of the trace chosen from the first pop-up menu. The numeric parameter color will have a value of 1, 2 or 3, corresponding to red, green and blue.

In the preceding example, we needed a trace name to pass to the ModifyGraph operation. In another common situation, we need a wave reference to operate on. For example:

```
Menu "Macros"
   "Smooth Wave In Graph...",SmoothWaveInGraphDialog()
End

Function SmoothWaveInGraphDialog()
   String traceName
   Prompt traceName,"Wave",popup,TraceNameList("",";",1)
   DoPrompt "Smooth Wave In Graph",traceName
```

```
   WAVE w = TraceNameToWaveRef("", traceName)
   Smooth 5, w
End
```

The traceName parameter alone is not sufficient to specify which wave we want to smooth because it does not identify in which data folder the wave resides. The TraceNameToWaveRef function returns a wave reference which solves this problem. See **Wave Reference Functions** on page IV-173 for details.

Saving Parameters for Reuse

It is possible to write a procedure that presents a simple input dialog with default values for the parameters saved from the last time it was invoked. To accomplish this, we use global variables to store the values between calls to the procedure. Here is an example that saves one numeric and one string variable.

```
Function TestDialog()
   String savDF = GetDataFolder(1)
   NewDataFolder/O/S root:Packages
   NewDataFolder/O/S :TestDialog

   Variable num = NumVarOrDefault("gNum", 42)
   Prompt num, "Enter a number"
   String str = StrVarOrDefault("gStr", "Hello")
   Prompt str, "Enter a string"
   DoPrompt "test",num,str

   Variable/G gNum = num      // Save for next time
   String/G gStr = str

   // Put function body here
   Print num,str

   SetDataFolder savDF
End
```

This example illustrates the NumVarOrDefault and StrVarOrDefault functions. These functions return the value of a global variable or a default value if the global variable does not exist. 42 is the default value for gNum. NumVarOrDefault will return 42 if gNum does not exist. If gNum does exist, it will return the value of gNum. Similarly, “Hello” is the default value for gStr. StrVarOrDefault will return “Hello” if gStr does not exist. If gStr does exist, it will return the value of gStr.

Multiple Simple Input Dialogs

Prompt statements can be located anywhere within the body of a function and they do not need to be grouped together, although it will aid code readability if associated Prompt and DoPrompt code is kept together. Functions may contain multiple DoPrompt statements, and Prompt statements can be reused or redefined.

The following example illustrates multiple simple input dialogs and prompt reuse:

```
Function Example()
   Variable a= 123
   Variable/C ca= cmplx(3,4)
   String s

   Prompt a,"Enter a value"
   Prompt ca,"Enter complex value"
   Prompt s,"Enter a string", popup "red;green;blue"
   DoPrompt "Enter Values",a,s,ca
   if(V_Flag)
      Abort "The user pressed Cancel"
   endif

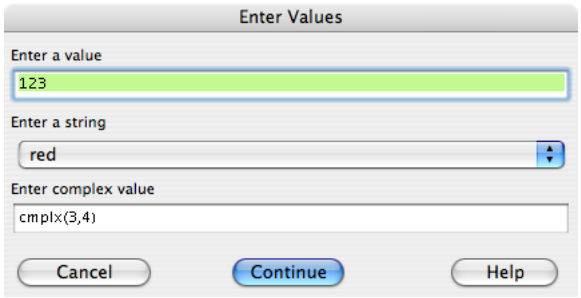
   Print "a= ",a,"s= ",s,"ca=",ca
```

```
   Prompt a,"Enter a again please"
   Prompt s,"Type a string"
   DoPrompt "Enter Values Again", a,s

   if(V_Flag)
      Abort "The user pressed Cancel"
   endif

   Print "Now a=",a," and s=",s
End
```

When this function is executed, it will produce two simple input dialogs, one after the other after the user clicks Continue; following is the first dialog:



Displaying an Open File Dialog

You can display an Open File dialog to allow the user to choose a file to be used with a subsequent command. For example, the user can choose a file which you will then use in a **LoadWave** command. The Open File dialog is displayed using an **Open**/D/R command. Here is an example:

```
Function/S DoOpenFileDialog()
   Variable refNum
   String message = "Select a file"
   String outputPath
   String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
   fileFilters += "All Files:.*;"

   Open /D /R /F=fileFilters /M=message refNum
   outputPath = S_fileName

   return outputPath    // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays an Open File dialog. If the user chooses a file and clicks the Open button, the Open operation returns the full path to the file in the S_fileName output string variable. If the user cancels, Open sets S_fileName to "".

The /M flag is used to set the prompt message.

The /F flag is used to control the file filter which determines what kinds of files the user can select. This is explained further under **Open File Dialog File Filters**.

Displaying a Multi-Selection Open File Dialog

In Igor Pro 6.1 or later, you can display an Open File dialog to allow the user to choose multiple files to be used with subsequent commands. The multi-selection Open File dialog is displayed using an **Open**/D/R/MULT=1 command. The list of files selected is returned via S_fileName in the form of a carriage-return-delimited list of full paths.

Here is an example:

```
Function/S DoOpenMultiFileDialog()
   Variable refNum
   String message = "Select one or more files"
   String outputPaths
   String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
   fileFilters += "All Files:.*;"

   Open /D /R /MULT=1 /F=fileFilters /M=message refNum
   outputPaths = S_fileName

   if (strlen(outputPaths) == 0)
      Print "Cancelled"
   else
      Variable numFilesSelected = ItemsInList(outputPaths, "\r")
      Variable i
      for(i=0; i<numFilesSelected; i+=1)
         String path = StringFromList(i, outputPaths, "\r")
         Printf "%d: %s\r", i, path
      endfor
   endif

   return outputPaths   // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays an Open File dialog. Because /MULT=1 was used, if the user chooses one or more files and clicks the Open button, the Open operation returns the list of full paths to files in the S_fileName output string variable. If the user cancels, Open sets S_fileName to "".

The list of full paths is delimited with a carriage return character, represented by "\r" in the example above. We use carriage return as the delimiter because the customary delimiter, semicolon, is a legal character in a Macintosh file name.

The /M flag is used to set the prompt message.

The /F flag is used to control the file filter which determines what kinds of files the user can select. This is explained further under **Open File Dialog File Filters**.

Open File Dialog File Filters

The **Open** operation displays the open file dialog if you use the /D/R flags or if the file to be opened is not fully specified using the pathName and fileNameStr parameters. The Open File dialog includes a file filter menu that allows the user to choose the type of file to be opened. By default this menus contain "Plain Text Files" and "All Files". You can use the /T and /F flags to override the default filter behavior.

The /T flag uses obsolescent Macintosh file types or file name extensions consisting of a dot plus three characters. The /F flag, added in Igor Pro 6.10, supports file name extensions only (not Macintosh file types) and extensions can be from one to 31 characters. Procedures written for Igor Pro 6.10 or later should use the /F flag in most cases but can use /T or both /T and /F. Procedures that must run with Igor Pro 6.0x and earlier must use the /T flag.

Using the /T=typeStr flag, you specify acceptable Macintosh-style file types represented by four-character codes (e.g., "TEXT") or acceptable three-character file name extensions (e.g., ".txt"). The pattern "????" means "any type of file" and is represented by "All Files" in the filter menu.

typeStr may contain multiple file types or extensions (e.g., "TEXTEPSF????" or ".txt.eps????"). Each file type or extension must be exactly four characters in length. Consequently the /T flag can accommodate only three-character file name extensions. Each file type or extension creates one entry in the Open File dialog filter menu.

If you use the /T flag, the Open operation automatically adds a filter for All Files ("????") if you do not add one explicitly.

Igor maps Macintosh file types to extensions. For example, if you specify /T="TEXT", you can open files with the extension ".txt" as well as any file whose Macintosh file type property is 'TEXT'. Igor does similar mappings for other extensions. See **File Types and Extensions** on page III-404 for details.

Using the /F=fileFilterStr flag, you specify a filter menu string plus acceptable file name extensions for each filter. fileFilterStr specifies one or more filters in a semicolon-separated list. For example, this specifies three filters:

```
String fileFilters = "Data Files (*.txt,*.dat,*.csv):.txt,.dat,.csv;"
fileFilters += "HTML Files (*.htm,*.html):.htm,.html;"
fileFilters += "All Files:.*;"
Open /F=fileFilters . . .
```

Each file filter consists of a filter menu string (e.g., "Data Files") followed by a colon, followed by one or more file name extensions (e.g., ".txt,.dat,.csv") followed by a semicolon. The syntax is rigid - no extra characters are allowed. In this example the filter menu would contain "Data Files" and would accept any file with a ".txt", ".dat", or ".csv" extension. ".*" creates a filter that accepts any file.

If you use the /F flag, it is up to you to add a filter for All Files as shown above. It is recommended that you do this.

On the Macintosh, selecting All Files allows you to navigate into packages (folders that appear in the Finder to be files).

Displaying a Save File Dialog

You can display a Save File dialog to allow the user to choose a file to be created or overwritten by a subsequent command. For example, the user can choose a file which you will then create or overwrite via a Save command. The Save File dialog is displayed using an **Open**/D command. Here is an example:

```
Function/S DoSaveFileDialog()
   Variable refNum
   String message = "Save a file"
   String outputPath
   String fileFilters = "Data Files (*.txt):.txt;"
   fileFilters += "All Files:.*;"

   Open /D /F=fileFilters /M=message refNum
   outputPath = S_fileName

   return outputPath    // Will be empty if user canceled
End
```

Here the Open operation does not actually open a file but instead displays a Save File dialog. If the user chooses a file and clicks the Save button, the Open operation returns the full path to the file in the S_fileName output string variable. If the user cancels, Open sets S_fileName to "".

The /M flag is used to set the prompt message.

The /F flag is used to control the file filter which determines what kinds of files the user can create. This is explained further under **Save File Dialog File Filters**.

Save File Dialog File Filters

The Save File dialog includes a file filter menu that allows the user to choose the type of file to be saved. By default this menus contain "Plain Text File" and, on Windows only, "All Files". You can use the /T and /F flags to override the default filter behavior.

The /T and /F flags work as explained under Open File Dialog File Filters. Using the /F flag for a Save File dialog, you would typically specify just one filter plus All Files, like this:

String fileFilters = "Data File (*.dat):.dat;"

fileFilters += "All Files:.*;"

Open /F=fileFilters . . .

On Windows, the file filter chosen in the Save File dialog determines the extension for the file being saved. For example, if the "Plain Text Files" filter is selected, the ".txt" extension is added if you don't explicitly enter it in the File Name edit box. However if you select the "All Files" filter then no extension is automatically added and the final file name is whatever you enter in the File Name edit box. You should include the "All Files" filter if you want the user to be able to specify a file name with any extension. If you want to force the file name extension to an extension of your choice rather than the user's, omit the "All Files" filter.

On Macintosh, the final file name is whatever you enter in the Save As edit box. The only significance of the selected file filter is that it controls the extension used if you click the Add/Fix Extension button. "All Files" has no significance in the Macintosh Save File dialog and therefore is ignored if it is the last file type specified using /T.

On the Macintosh, in the rare event that you want to save a file inside a package (a folder that appears as a file in the Finder), press Command-Option as the dialog is presented. This will allow you to navigate inside packages.

Using Open in a Utility Routine

To be as general and useful as possible, a utility routine that acts on a file should have a pathName parameter and a fileName parameter, like this:

```
Function ShowFileInfo(pathName, fileName)
   String pathName   // Name of symbolic path or "" for dialog.
   String fileName   // File name or "" for dialog.

   <Show file info here>
End
```

This provides flexibility to the calling function. The caller can supply a valid symbolic path name and a simple leaf name in fileName, a valid symbolic path name and a partial path in fileName, or a full path in fileName in which case pathName is irrelevant.

If pathName and fileName fully specify the file of interest, you want to just open the file and perform the requested action. However, if pathName and fileName do not fully specify the file of interest, you want to display an Open File dialog so the user can choose the file. This is accomplished by using the **Open** operation's /D=2 flag (added in Igor Pro 6.1).

With /D=2, if pathName and fileName fully specify the file, the Open operation merely sets the S_fileName output string variable to the full path to the file. If pathName and fileName do not fully specify the file, Open displays an Open File dialog and then sets the S_fileName output string variable to the full path to the file. If the user cancels the Open File dialog, Open sets S_fileName to "". In all cases, Open/D=2 just sets S_fileName and does not actually open the file.

If pathName and fileName specify an alias (*Macintosh*) or shortcut (*Windows*), Open/D=2 returns the file referenced by the alias or shortcut.

Here is how you would use Open /D=2.

```
Function ShowFileInfo(pathName, fileName)
   String pathName      // Name of symbolic path or "" for dialog.
   String fileName      // File name or "" for dialog.
```

```
   Variable refNum

   Open /D=2 /R /P=$pathName refNum as fileName    // Sets S_fileName

   if (strlen(S_fileName) == 0)
      Print "ShowFileInfo was canceled"
   else
      String fullPath = S_fileName
      Print fullPath
      Open /R refNum as fullPath
      FStatus refNum    // Sets S_info
      Print S_info
      Close refNum
   endif
End
```

In this case, we wanted to open the file for reading. To create a file and open it for writing, omit /R from both calls to Open.

Pause For User

The **PauseForUser** operation (see page V-476) allows an advanced programmer to create a more sophisticated semimodal user interface. When you invoke it from a procedure, Igor suspends procedure execution and the user can interact with graph, table or control panel windows using the mouse or keyboard. Execution continues when the user kills the main window specified in the PauseForUser command.

Pausing execution can serve two purposes. First, the programmer can pause function execution so that the user can, for example, adjust cursors in a graph window before continuing with a curve fit. In this application, the programmer creates a control panel with a continue button that the user presses after adjusting the cursors in the target graph. Pressing the continue button kills the host control panel (see example below).

In the second application, the programmer may wish to obtain input from the user in a more sophisticated manner than can be done using DoPrompt commands. This method uses a control panel as the main window with no optional target window. It is similar to the control panel technique shown above, except that it is modal.

Following are some examples of how you can use the **PauseForUser** operation (see page V-476) in your own user functions.

PauseForUser Simple Cursor Example

This example shows how to allow the user to adjust cursors on a graph while a procedure is executing. Most of the work is done by the UserCursorAdjust function. UserCursorAdjust is called by the Demo function which first creates a graph and shows the cursor info panel.

This example illustrates two modes of PauseForUser. When called with autoAbortSecs=0, UserCursorAdjust calls PauseForUser without the /C flag in which case PauseForUser retains control until the user clicks the Continue button.

When called with autoAbortSecs>0, UserCursorAdjust calls PauseForUser/C. This causes PauseForUser to handle any pending events and then return to the calling procedure. The procedure checks the V_flag variable, set by PauseForUser, to determine when the user has finished interacting with the graph. PauseForUser/C, which requires Igor Pro 6.1 or later, is for situations where you want to do something while the user interacts with the graph.

To try this yourself, copy and paste all three routines routines below into the procedure window of a new experiment and then run the Demo function with a value of 0 and again with a value such as 30.

```
Function UserCursorAdjust(graphName,autoAbortSecs)
   String graphName
   Variable autoAbortSecs

   DoWindow/F $graphName                  // Bring graph to front
```

```
   if (V_Flag == 0)                        // Verify that graph exists
      Abort "UserCursorAdjust: No such graph."
      return -1
   endif

   NewPanel /K=2 /W=(187,368,437,531) as "Pause for Cursor"
   DoWindow/C tmp_PauseforCursor          // Set to an unlikely name
   AutoPositionWindow/E/M=1/R=$graphName  // Put panel near the graph

   DrawText 21,20,"Adjust the cursors and then"
   DrawText 21,40,"Click Continue."
   Button button0,pos={80,58},size={92,20},title="Continue"
   Button button0,proc=UserCursorAdjust_ContButtonProc
   Variable didAbort= 0
   if( autoAbortSecs == 0 )
      PauseForUser tmp_PauseforCursor,$graphName
   else
      SetDrawEnv textyjust= 1
      DrawText 162,103,"sec"
      SetVariable sv0,pos={48,97},size={107,15},title="Aborting in "
      SetVariable sv0,limits={-inf,inf,0},value= _NUM:10
      Variable td= 10,newTd
      Variable t0= ticks
      Do
         newTd= autoAbortSecs - round((ticks-t0)/60)
         if( td != newTd )
            td= newTd
            SetVariable sv0,value= _NUM:newTd,win=tmp_PauseforCursor
            if( td <= 10 )
               SetVariable sv0,valueColor= (65535,0,0),win=tmp_PauseforCursor
            endif
         endif
         if( td <= 0 )
            DoWindow/K tmp_PauseforCursor
            didAbort= 1
            break
         endif

         PauseForUser/C tmp_PauseforCursor,$graphName
      while(V_flag)
   endif
   return didAbort
End

Function UserCursorAdjust_ContButtonProc(ctrlName) : ButtonControl
   String ctrlName

   DoWindow/K tmp_PauseforCursor             // Kill panel
End

Function Demo(autoAbortSecs)
   Variable autoAbortSecs

   Make/O jack;SetScale x,-5,5,jack
   jack= exp(-x^2)+gnoise(0.1)
   DoWindow Graph0
   if( V_Flag==0 )
      Display jack
      ShowInfo
   endif
```

```
   if (UserCursorAdjust("Graph0",autoAbortSecs) != 0)
      return -1
   endif

   if (strlen(CsrWave(A))>0 && strlen(CsrWave(B))>0)// Cursors are on trace?
      CurveFit gauss,jack[pcsr(A),pcsr(B)] /D
   endif
End
```

PauseForUser Advanced Cursor Example

Now for something a bit more complex. Here we modify the preceding example to include a Cancel button. For this, we need to return information about which button was pressed. Although we could do this by creating a single global variable in the root data folder, we use a slightly more complex technique using a temporary data folder. This technique is especially useful for more complex panels with multiple output variables because it limits any worry about name conflicts to the data folder itself. It also allows much easier clean up because we can kill the entire data folder and everything in it with just one operation.

```
Function UserCursorAdjust(graphName)
   String graphName

   DoWindow/F $graphName   // Bring graph to front
   if (V_Flag == 0)        // Verify that graph exists
      Abort "UserCursorAdjust: No such graph."
      return -1
   endif

   NewDataFolder/O root:tmp_PauseforCursorDF
   Variable/G root:tmp_PauseforCursorDF:canceled= 0

   NewPanel/K=2 /W=(139,341,382,450) as "Pause for Cursor"
   DoWindow/C tmp_PauseforCursor          // Set to an unlikely name
   AutoPositionWindow/E/M=1/R=$graphName  // Put panel near the graph

   DrawText 21,20,"Adjust the cursors and then"
   DrawText 21,40,"Click Continue."
   Button button0,pos={80,58},size={92,20},title="Continue"
   Button button0,proc=UserCursorAdjust_ContButtonProc
   Button button1,pos={80,80},size={92,20}
   Button button1,proc=UserCursorAdjust_CancelBProc,title="Cancel"

   PauseForUser tmp_PauseforCursor,$graphName

   NVAR gCaneled= root:tmp_PauseforCursorDF:canceled
   Variable canceled= gCaneled   // Copy from global to local
                                 // before global is killed
   KillDataFolder root:tmp_PauseforCursorDF

   return canceled
End

Function UserCursorAdjust_ContButtonProc(ctrlName) : ButtonControl
   String ctrlName

   DoWindow/K tmp_PauseforCursor    // Kill self
End

Function UserCursorAdjust_CancelBProc(ctrlName) : ButtonControl
   String ctrlName

   Variable/G root:tmp_PauseforCursorDF:canceled= 1
   DoWindow/K tmp_PauseforCursor    // Kill self
End
```

And now a demo that uses the new version:

```
Function Demo()
   Make/O jack;SetScale x,-5,5,jack
   jack= exp(-x^2)+gnoise(0.1)
   DoWindow Graph0
   if (V_Flag==0)
      Display jack
      ShowInfo
   endif
   Variable rval= UserCursorAdjust("Graph0")
   if (rval == -1)            // Graph name error?
      return -1;
   endif
   if (rval == 1)             // User canceled?
      DoAlert 0,"Canceled"
      return -1;
   endif
   CurveFit gauss,jack[pcsr(A),pcsr(B)] /D
End
```

PauseForUser Control Panel Example

The following is a very simple example of using a control panel as modal dialog. The panel was designed by first manually creating a data folder with a few variables and then creating a panel. When the panel was designed properly, it was closed to create a recreation macro. Lines from the macro were then used in the body of the function.

```
Function UserGetInputPanel_ContButton(ctrlName) : ButtonControl
   String ctrlName

   DoWindow/K tmp_GetInputPanel     // kill self
End

// Call with these variables already created and initialized:
//    root:tmp_PauseForUserDemo:numvar
//    root:tmp_PauseForUserDemo:strvar
Function DoMyInputPanel()
   NewPanel /W=(150,50,358,239)
   DoWindow/C tmp_GetInputPanel        // set to an unlikely name
   DrawText 33,23,"Enter some data"
   SetVariable setvar0,pos={27,49},size={126,17},limits={-Inf,Inf,1}
   SetVariable setvar0,value= root:tmp_PauseForUserDemo:numvar
   SetVariable setvar1,pos={24,77},size={131,17},limits={-Inf,Inf,1}
   SetVariable setvar1,value= root:tmp_PauseForUserDemo:strvar
   Button button0,pos={52,120},size={92,20}
   Button button0,proc=UserGetInputPanel_ContButton,title="Continue"

   PauseForUser tmp_GetInputPanel
End

Function Demo1()
   NewDataFolder/O root:tmp_PauseForUserDemo
   Variable/G root:tmp_PauseForUserDemo:numvar= 12
   String/G root:tmp_PauseForUserDemo:strvar= "hello"

   DoMyInputPanel()

   NVAR numvar= root:tmp_PauseForUserDemo:numvar
   SVAR strvar= root:tmp_PauseForUserDemo:strvar

   printf "You entered %g and %s\r",numvar,strvar

   KillDataFolder root:tmp_PauseForUserDemo
End
```

For comparison, here is the equivalent using the simple input dialog technique:

```
Function Demo2()
   Variable numvar= 12
   String strvar= "hello"
   Prompt numvar,"numvar:"
   Prompt strvar,"strvar:"
   DoPrompt "Enter some data",numvar,strvar
   printf "You entered %g and %s\r",numvar,strvar
End
```

Progress Windows

Sometimes when performing a long calculation, you may want to put up an indicator that the calculation is in progress, perhaps showing how far along it is, and perhaps providing an abort button. As of Igor Pro 6.1, you can use a control panel window for this task using the **DoUpdate** /E and /W flags and the mode=4 setting for **ValDisplay**.

DoUpdate /W=win /E=1 marks the specified window as a progress window that can accept mouse events while user code is executing. The /E flag need be used only once to mark the panel but it does not hurt to use it in every call. This special state of the control panel is automatically cleared when procedure execution finishes and Igor's outer loop again runs.

For a window marked as a progress window, DoUpdate sets V_Flag to 2 if a mouse up happened in a button since the last call. When this occurs, the full path to the subwindow containing the button is stored in S_path and the name of the control is stored in S_name.

Here is a simple example that puts up a progress window with a progress bar and a quit button. Try each of the four input flag combinations.

```
// Try simpletest(0,0) and simpletest(1,0), simpletest(0,1) and simpletest(1,1)
Function simpletest(indefinite, useIgorDraw)
   Variable indefinite
   Variable useIgorDraw// True to use Igor's own draw method rather than native

   NewPanel /N=ProgressPanel /W=(285,111,739,193)
   ValDisplay valdisp0,pos={18,32},size={342,18}
   ValDisplay valdisp0,limits={0,100,0},barmisc={0,0}
   ValDisplay valdisp0,value= _NUM:0
   if( indefinite )
      ValDisplay valdisp0,mode= 4// candy stripe
   else
      ValDisplay valdisp0,mode= 3// bar with no fractional part
   endif
   if( useIgorDraw )
      ValDisplay valdisp0,highColor=(0,65535,0)
   endif
   Button bStop,pos={375,32},size={50,20},title="Stop"
   DoUpdate /W=ProgressPanel /E=1// mark this as our progress window

   Variable i,imax= indefinite ? 10000 : 100
   for(i=0;i<imax;i+=1)
      Variable t0= ticks
      do
      while( ticks < (t0+3) )
      if( indefinite )
         ValDisplay valdisp0,value= _NUM:1,win=ProgressPanel
      else
         ValDisplay valdisp0,value= _NUM:i+1,win=ProgressPanel
      endif
      DoUpdate /W=ProgressPanel
      if( V_Flag == 2 )// we only have one button and that means stop
         break
```

```
      endif
   endfor
   KillWindow ProgressPanel
End
```

When performing complex calculations, it is often difficult to insert DoUpdate calls in the code. In this case, you can use a window hook that responds to event #23, spinUpdate. This is called at the same time that the beachball cursor spins. The hook can then update the window's control state and then call DoUpdate/W on the window. If the window hook returns non-zero, then an abort is performed. If you desire a more controlled quit, you might set a global variable that your calculation code can test. The following example provides an indefinite indicator and an abort button. Note that if the abort button is pressed, the window hook kills the progress window since otherwise the abort would cause the window to remain.

```
// Example: spinnertest(100)
Function spinnertest(nloops)
   Variable nloops

   Variable useIgorDraw=0  // set true for Igor draw method rather than native

   NewPanel/FLT /N=myProgress/W=(285,111,739,193)
   ValDisplay valdisp0,pos={18,32},size={342,18}
   ValDisplay valdisp0,limits={0,100,0},barmisc={0,0}
   ValDisplay valdisp0,value= _NUM:0
   ValDisplay valdisp0,mode=4    // candy stripe
   if( useIgorDraw )
      ValDisplay valdisp0,highColor=(0,65535,0)
   endif
   Button bStop,pos={375,32},size={50,20},title="Abort"
   SetActiveSubwindow _endfloat_
   DoUpdate/W=myProgress/E=1     // mark this as our progress window

   SetWindow myProgress,hook(spinner)= MySpinner

   Variable t0= ticks,i
   for(i=0;i<nloops;i+=1)
      PerformLongCalc(1e6)
   endfor
   Variable timeperloop= (ticks-t0)/(60*nloops)

   KillWindow myProgress

   print "time per loop=",timeperloop
End

Function MySpinner(s)
   STRUCT WMWinHookStruct &s

   if( s.eventCode == 23 )
      ValDisplay valdisp0,value= _NUM:1,win=$s.winName
      DoUpdate/W=$s.winName
      if( V_Flag == 2 )    // we only have one button and that means abort
         KillWindow $s.winName
         return 1
      endif
   endif
   return 0
End

Function PerformLongCalc(nmax)
   Variable nmax
```

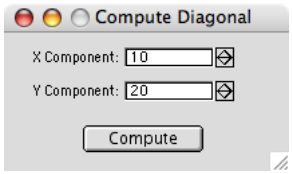
```
   Variable i,s
   for(i=0;i<nmax;i+=1)
      s+= sin(i/nmax)
   endfor
End
```

Control Panels and Event-Driven Programming

The CalcDiagDialog function shown above creates a modal dialog. "Modal" means that the function retains complete control until the user clicks Cancel or Continue. The user can not activate another window or choose a menu item until the dialog is dismissed.

This section shows how to implement the same functionality using a control panel as a modeless dialog. "Modeless" means that the user can activate another window or choose a menu item at any time. The modeless window accepts input whenever the user wants to enter it but does not block the user from accessing other windows.

The control panel looks like this:



The code implementing this control panel is given below. Before we look at the code, here is some explanation of the thinking behind it.

The X Component and Y Component controls are SetVariable controls. Each SetVariable control must be attached to a global variable. To keep the global variables from cluttering the user's space, we buried them in a data folder named root:Packages:DiagonalControlPanel.

We want the globals to be automatically created so the user does not need to worry about them, so we wrote a routine (DisplayDiagonalControlPanel) that makes sure that the variables and their containing data folders exist. The routine then creates the control panel or, if it already exists, just brings it to the front. We added a menu item to the Macros menu so the user can easily invoke DisplayDiagonalControlPanel.

We built the control panel manually using techniques explained in Chapter III-14, **Controls and Control Panels**. Then we closed it so Igor would create a display recreation macro which we named DiagonalControlPanel. We then manually tweaked the macro to attach the SetVariable controls to the desired globals and to set the panel's behavior when the user clicks the close button.

Here are the procedures.

```
// Add a menu item to display the control panel.
Menu "Macros"
   "Display Diagonal Control Panel", DisplayDiagonalControlPanel()
End

// This is the display recreation macro, created by Igor
// and then manually tweaked. The parts that were tweaked
// are shown in bold. NOTE: Some lines are wrapped to fit on the page.
Window DiagonalControlPanel() : Panel
   PauseUpdate; Silent 1   // building window...

   NewPanel/W=(162,95,375,198)/K=1 as "Compute Diagonal"

   SetVariable XSetVar,pos={22,11},size={150,15},title="X Component:"
   SetVariable XSetVar,limits={-Inf,Inf,1},value=
                  root:Packages:DiagonalControlPanel:gXComponent
```

```
   SetVariable YSetVar,pos={22,36},size={150,15},title="Y Component:"
   SetVariable YSetVar,limits={-Inf,Inf,1},value=
                  root:Packages:DiagonalControlPanel:gYComponent

   Button ComputeButton,pos={59,69},size={90,20},
                        proc=ComputeDiagonalProc,title="Compute"
EndMacro

// This is the action procedure for the Compute button.
// We created it using the Button dialog.
Function ComputeDiagonalProc(ctrlName) : ButtonControl
   String ctrlName

   String dfSave = GetDataFolder(1)
   SetDataFolder root:Packages:DiagonalControlPanel

   NVAR gXComponent, gYComponent    // Access current data folder.
   Variable diagonal
   diagonal = sqrt(gXComponent^2 + gYComponent^2)
   Printf "Diagonal=%g\r", diagonal

   SetDataFolder dfSave
End

// This is the top level routine which makes sure that the globals
// and their enclosing data folders exist and then makes sure that
// the control panel is displayed.
Function DisplayDiagonalControlPanel()
   // If the panel is already created, just bring it to the front.
   DoWindow/F DiagonalControlPanel
   if (V_Flag != 0)
      return 0
   endif

   String dfSave = GetDataFolder(1)

   // Create a data folder in Packages to store globals.
   NewDataFolder/O/S root:Packages
   NewDataFolder/O/S root:Packages:DiagonalControlPanel

   // Create global variables used by the control panel.
   Variable xComponent = NumVarOrDefault(":gXComponent", 10)
   Variable/G gXComponent = xComponent
   Variable yComponent = NumVarOrDefault(":gYComponent", 20)
   Variable/G gYComponent = yComponent

   // Create the control panel.
   Execute "DiagonalControlPanel()"

   SetDataFolder dfSave
End
```

Although this example is very simple, it illustrates the process of creating a control panel that functions as a modeless dialog. There are many more examples of this in the Examples folder. See Chapter III-14, **Controls and Control Panels**, for more information on building control panels.

Detecting a User Abort

If you have written a user-function that takes a long time to execute, you may want to provide a way for the user to abort it. Your first instinct might be to create a control panel with a Stop button. This won't work

because Igor does not look at controls while your user function is running. Instead, you must detect that the user is pressing Escape, as this example illustrates:

```
Function PressEscapeToAbort(phase, title, message)
   Variable phase    // 0: Display control panel with message.
                     // 1: Test if Escape key is pressed.
                     // 2: Close control panel.
   String title      // Title for control panel.
   String message    // Tells user what you are doing.

   if (phase == 0)   // Create panel
      DoWindow/F PressEscapePanel
      if (V_flag == 0)
         NewPanel/K=1 /W=(100,100,350,200)
         DoWindow/C PressEscapePanel
         DoWindow/T PressEscapePanel, title
      endif
      TitleBox Message,pos={7,8},size={69,20},title=message
      String abortStr = "Press escape to abort"
      TitleBox Press,pos={6,59},size={106,20},title=abortStr
      DoUpdate
   endif

   if (phase == 1)   // Test for Escape key
      Variable doAbort = 0
      if (GetKeyState(0) & 32)      // Is Escape key pressed now?
         doAbort = 1
      else
         if (strlen(message) != 0)  // Want to change message?
            TitleBox Message,title=message
            DoUpdate
         endif
      endif
      return doAbort
   endif

   if (phase == 2)   // Kill panel
      DoWindow/K PressEscapePanel
   endif

   return 0
End

Function Demo()
   // Create panel
   PressEscapeToAbort(0, "Demonstration", "This is a demo")

   Variable startTicks = ticks
   Variable endTicks = startTicks + 10*60
   Variable lastMessageUpdate = startTicks

   do
      String message
      message = ""
      if (ticks>=lastMessageUpdate+60) // Time to update message?
         Variable remaining = (endTicks - ticks) / 60
         sprintf message, "Time remaining: %.1f seconds", remaining
         lastMessageUpdate = ticks
      endif

      if (PressEscapeToAbort(1, "", message))
         Print "Test aborted by Escape key."
         break
```

```
      endif
   while(ticks < endTicks)

   PressEscapeToAbort(2, "", "")       // Kill panel.
End
```

Creating a Contextual Menu

You can use the **PopupContextualMenu** operation to create a pop-up menu in response to a control-click (*Macintosh*) or right-click. You would do this from a window hook function or from the action procedure for a control in a control panel.

In this example, we create a control panel with a list. When the user right-clicks on the list, Igor sends a mouse-down event to the listbox procedure, TickerListProc in this case. The listbox procedure uses the eventMod field of the WMListboxAction structure to determine if the click is a right-click. If so, it calls HandleTickerListRightClick which calls PopupContextualMenu to display the contextual menu.

```
Menu "Macros"

   "Show Demo Panel", ShowDemoPanel()
End

static Function HandleTickerListRightClick()
   String popupItems = ""
   popupItems += "Refresh;"

   PopupContextualMenu popupItems
   strswitch (S_selection)
      case "Refresh":
         DoAlert 0, "Here is where you would refresh the ticker list."
         break
   endswitch
End

Function TickerListProc(lba) : ListBoxControl
   STRUCT WMListboxAction &lba

   switch (lba.eventCode)
      case 1:                     // Mouse down
         if (lba.eventMod & 0x10)// Right-click?
            HandleTickerListRightClick()
         endif
         break
   endswitch

   return 0
End

Function ShowDemoPanel()
   DoWindow/F DemoPanel
   if (V_flag != 0)
      return 0 // Panel already exists.
   endif

   // Create panel data.
   Make/O/T ticketListWave = {{"AAPL","IBM","MSFT"}, {"90.25","86.40","17.17"}}

   // Create panel.
   NewPanel /N=DemoPanel /W=(321,121,621,321) /K=1
   ListBox TickerList,pos={48,16},size={200,100},fSize=12
   ListBox TickerList,listWave=root:ticketListWave
```

```
   ListBox TickerList,mode= 1,selRow= 0, proc=TickerListProc
End
```

Cursors as Input Device

You can use the cursors on a trace in a graph to identify the data to be processed.

The examples shown above using PauseForUser are modal - the user adjusts the cursors in the middle of procedure execution and can do nothing else. This technique is nonmodal — the user is expected to adjust the cursors before invoking the procedure.

This function does a straight-line curve fit through the data between cursor A (the round cursor) and cursor B (the square cursor). This example is written to handle both waveform and XY data.

```
Function FitLineBetweenCursors()
   Variable isXY

   // Make sure both cursors are on the same wave.
   WAVE wA = CsrWaveRef(A)
   WAVE wB = CsrWaveRef(B)
   String dfA = GetWavesDataFolder(wA, 2)
   String dfB = GetWavesDataFolder(wB, 2)
   if (CmpStr(dfA, dfB) != 0)
      Abort "Both cursors must be on the same wave."
      return -1
   endif

   // Find the wave that the cursors are on.
   WAVE yWave = CsrWaveRef(A)

   // Decide if this is an XY pair.
   WAVE xWave = CsrXWaveRef(A)
   isXY = WaveExists(xWave)

   if (isXY)
      CurveFit line yWave(xcsr(A),xcsr(B)) /X=xWave /D
   else
      CurveFit line yWave(xcsr(A),xcsr(B)) /D
   endif
End
```

This technique is demonstrated in the **Fit Line Between Cursors** example experiment in the "Examples:Curve Fitting" folder.

Advanced programmers can set things up so that a hook function is called whenever the user adjusts the position of a cursor. For details, see **Cursors — Moving Cursor Calls Function** on page IV-294.

Marquee Menu as Input Device

A marquee is the dashed-line rectangle that you get when you click and drag diagonally in a graph or page layout. It is used for expanding and shrinking the range of axes and for specifying an area of a layout. You can use the marquee as an input device for your procedures. This is a relatively advanced technique.

This menu definition adds a user-defined item to the graph marquee menu:

```
Menu "GraphMarquee"
   "Print Marquee Coordinates", PrintMarqueeCoords()
End
```

To add an item to the layout marquee menu, use LayoutMarquee instead of GraphMarquee.

When the user chooses Print Marquee Coordinates, the following function runs. It prints the coordinates of the marquee in the history area. It assumes that the graph has left and bottom axes.

```
Function PrintMarqueeCoords()
   String format
   GetMarquee/K left, bottom
   format = "flag: %g; left: %g; top: %g; right: %g; bottom: %g\r"
   printf format, V_flag, V_left, V_top, V_right, V_bottom
End
```

The ability to add items to the marquee menus through GraphMarquee and LayoutMarquee menu definitions was added in Igor Pro 5. Before that, the GraphMarquee and LayoutMarquee procedure subtype keywords were used. This technique is no longer recommended but is still supported.

The use of the marquee menu as in input device is demonstrated in the **Marquee Demo** and **Delete Points from Wave** example experiments.

Polygon as Input Device

This technique is similar to the marquee technique except that you can identify a nonrectangular area. It is implemented using **FindPointsInPoly** operation (see page V-174).

Chapter
IV-7

Programming Techniques

Overview

This chapter discusses programming techniques and issues that go beyond the basics of the Igor programming language and which all Igor programmers should understand. Techniques for advanced programmers are discussed in Chapter IV-10, **Advanced Programming**.

The Include Statement

The include statement is a "compiler directive" that you can put in your procedure file to automatically open another procedure file. A typical include statement looks like this:

```
#include <Split Axis>
```

This statement automatically opens the file "Split Axis.ipf" in the WaveMetrics Procedures folder. Once this statement has been compiled, you can call routines from that file. This is the recommended way to access procedure files that contain utility routines.

The # character at the beginning specifies that a compiler directive follows. Compiler directives must start at the far left edge of the procedure window with no leading tabs or spaces. Include statements can appear anywhere in the file but it is conventional to put them near the top.

It is possible to include a file which in turn includes other files that will automatically open.

Included files are opened when procedures are compiled. If you remove an include statement from a procedure file, the file will automatically close when you next compile.

There are four forms of the include statement specifying where files are located:

1. Igor searches for the named file in "Igor Pro Folder/WaveMetrics Procedures" and in any subfolders:

   `#include <`*`fileName`*`>`

   Example: `#include <Split Axis>`
2. Igor searches for the named file in "Igor Pro Folder/User Procedures" and "Igor Pro User Files/User Procedures" and in any subfolders:

   `#include "`*`fileName`*`"`

   Example: `#include "Test Utility Procs"`
3. Igor looks for the file only in the exact location specified:

   `#include "`*`full file path`*`"`

   Example: `#include "Hard Disk:Desktop Folder:Test Utility Procs"`
4. Igor looks for the file relative to the Igor Pro folder or the Igor Pro User Files folder or the folder containing the procedure file that contains the #include statement:

   `#include ":`*`partial file path`*`"`

   Example: `#include ":Spectroscopy Procedures:Voigt Procs"`

   Igor looks first relative to the Igor Pro Folder. If that fails, it looks relative to the **Igor Pro User Files** folder (requires Igor Pro 6.20 or later). If that fails it looks relative to the procedure file containing the #include statement (requires Igor Pro 6.00 or later) or, if the #include statement is in the built-in procedure window, relative to the experiment file (requires Igor Pro 6.02 or later).

   The name of the file being included must end with the standard ".ipf" extension but the extension is not used in the include statement.

Procedure File Version Information

If you create a procedure file to be used by other Igor users, it's a good idea to add version information to the file. You do this by putting a #pragma version statement in the procedure file. For example:

```
#pragma version = 1.10
```

This statement must appear with no indentation and must appear in the first 50 lines of the file. If Igor does not find the #pragma version statement and if Igor is running on Macintosh, it then looks for a `'vers',1`

resource. If Igor finds neither the #pragma statement nor the resource, it treats the file as version 1.00. 'vers' resources are obsolete but are still recognized by Igor.

Igor looks for the version information when the user invokes the File Information dialog from the Procedure menu. If the file has version information, Igor displays the version next to the file name in the dialog.

Igor also looks for version information when it opens an included file. An include statement can require a certain version of the included file using the following syntax:

```
#include <Bivariate Histogram> version>=1.03
```

If the required version of the procedure file is not available, Igor displays a warning to inform the user that the procedure file needs to be updated.

Turning the Included File's Menus Off

Normally an included procedure file's menus and menu items are displayed. However, if you are including a file merely to call one of its procedures, you may not want that file's menu items to appear. To suppress the file's menus and menu items, use:

```
#include <Decimation> menus=0
```

To use both the menus and version options, you must separate them with a comma:

```
#include <Decimation> menus=0, version>=1.1
```

Optionally Including Files

Compilation usually ceases if the included file isn't found. On occasion it is advantageous to allow compilation to proceed if an included file isn't present or is the wrong version. Optionally including a procedure file is appropriate only if the file truly isn't needed to make procedures compile or operate.

Use the "optional" keyword to optionally include a procedure file:

```
#include <Decimation> version>=1.1, optional
```

The "optional" keyword requires Igor 6.13 or later.

Writing General-Purpose Procedures

Procedures can be placed on a scale ranging from general to specific. Usually, the high-level procedures of a program are specific to the task at hand and call on more general, lower-level procedures. The most general procedures are often called "utility" procedures.

You can achieve a high degree of productivity by building a library of utility procedures that you reuse in different programs. In Igor, you can think of the routines in an experiment's built-in Procedure window as a program. It can call utility routines which should be stored in a separate procedure file so that they are available to multiple experiments.

The files stored in the WaveMetrics Procedures folder contain general-purpose procedures on which your high-level procedures can build. Use the include statement (see **The Include Statement** on page IV-145) to access these and other utility files.

When you write utility routines, you should keep them as general as possible so that they can be reused as much as possible. Here are some guidelines.

- Avoid the use of global variables as inputs or outputs. Using globals hard-wires the routine to specific names which makes it difficult to use and limits its generality.
- If you use globals to store state information between invocations of a routine, package the globals in data folders.

  WaveMetrics packages usually create data folders inside "root:Packages". We use the prefix "WM" for data folder names to avoid conflict with other packages. Follow this lead and should pick your own data folder names so as to minimize the chance of conflict with WaveMetrics packages or with others.

- Choose a clear and specific name for your utility routine.

  By choosing a name that says precisely what your utility routine does, you minimize the likelihood of collision with the name of another procedure. You also increase the readability of your program.
- Make functions which are used only internally by your procedures static.

  By making internal functions static (i.e., private), you minimize the likelihood of collision with the name of another procedure.

Programming with Liberal Names

Standard names in Igor may contain letters, numbers and the underscore character only. Starting with Igor Pro 3.0, it became possible to use wave names and data folder names that contain almost any character (see **Liberal Object Names** on page III-415). However, if you do use liberal names, some existing Igor procedures and extensions may break. Programmers will need to make changes to their procedures to ensure they will work with liberal names.

Whenever a liberal name is used in a command or expression, the name must be enclosed in single quotes. For example:

```
Make 'Wave 1', wave2, 'miles/hour'
'Wave 1' = wave2 + 'miles/hour'
```

Without the single quotes, Igor has no way to know where a particular name ends. This is a problem whenever Igor parses a command or statement. Igor parses commands at the following times:

- When it compiles a user-defined function.
- When it compiles the right-hand side of an assignment statement, including a formula (:= dependency expression).
- When it interprets a macro.
- When it interprets a command that you enter in the command line or via an Igor Text file.
- When it interprets a command you submit for execution via the Execute operation.
- When it interprets a command that an XOP submits for execution via the XOPCommand or XOPSilentCommand callback routines.

When you use an Igor dialog to generate a command, Igor automatically uses quotes where necessary.

Programmers need to be concerned about liberal names whenever they create a command and then execute it (via an Igor Text file, the Execute operation or the XOPCommand and XOPSilentCommand callback routines) or when creating a formula. In short, when you create something that Igor has to parse, names must be quoted if they are liberal. Names that are not liberal can be quoted or unquoted.

If you have a procedure that builds up a command in a string variable and then executes it via the Execute operation, you must use the PossiblyQuoteName function to provide the quotes if needed.

Here is a trivial example showing the old way of doing this along with the new, liberal-name aware way.

```
Function AddOneToWave(w)
   WAVE w

   String cmd
   String name = NameOfWave(w)

   // Here is the old way
   sprintf cmd, "%s += 1", name
   Execute cmd

   // Here is the new, liberal-name aware way
   sprintf cmd, "%s += 1", PossiblyQuoteName(name)
   Execute cmd
End
```

Imagine that you pass a wave named *wave 1* to this function. Using the old method, the Execute operation would see the following text:

```
wave 1 += 1
```

Igor will generate an error because it will try to find an operation, macro, function, wave or variable named *wave*.

Using the new method, the Execute operation would see the following text:

```
'wave 1' += 1
```

This works correctly because Igor sees 'wave 1' as a single name.

Depending on exactly what they do with their parameters, Igor procedures and extensions written before Igor Pro 3.0 or which have not been tested with liberal names may cause errors like this to occur. The safe route is to test all of the procedures and extensions that you rely on before routinely using liberal names.

When you pass a string expression containing a simple name to the $ operator, the name must not be quoted because Igor does no parsing:

```
String w = "wave 1"; Display $w                         // Right
String w = "'wave 1'"; Display $w                       // Wrong
```

However, when you pass a *path* in a string to $, any liberal names in the path must be quoted:

```
String path = "root:'My Data':'wave 1'"; Display $w   // Right
String path = "root:My Data:wave 1"; Display $w       // Wrong
```

For further explanation of liberal name quoting rules, see **Accessing Global Variables and Waves Using Liberal Names** on page IV-53.

Some built-in string functions return a list of waves. WaveList is the most common example. If liberal wave names are used, you will have to be extra careful when using the list of names. For example, you can't just append the list to the name of an operation that takes a list of names and then execute the resulting string. Rather, you will have to extract each name in turn, possibly quote it and then append it to the operation.

For example, the following will work if all wave names are standard but not if any wave names are liberal:

```
Execute "Display " + WaveList("*", ",", "")
```

Now you will need a string function that extracts out each name, possibly quotes it, and creates a new string using the new names separated by commas. The PossiblyQuoteList function in the WaveMetrics procedure file Strings as Lists does this. The preceding command becomes:

```
Execute "Display " + PossiblyQuoteList(WaveList("*", ",", ""), ",")
```

To include the Strings as Lists file in your procedures, see **The Include Statement** on page IV-145.

For details on using liberal names in user-defined functions, see **Accessing Global Variables and Waves Using Liberal Names** on page IV-53.

Programming with Data Folders

For general information on data folders, including syntax for using data folders in command line operations, see Chapter II-8, **Data Folders**.

Data folders provide a powerful way for intermediate and advanced programmers to organize their data and to reduce clutter. However, using data folders introduces some complexity in Igor programming. The name of a variable or wave is no longer sufficient to uniquely identify it because the name alone does not indicate in which data folder it resides.

There are two main uses for data folders:

- To store globals used by procedures to keep track of their state.
- To store runs of data with identical structures.

Storing Procedure Globals

If you create packages of procedures, for example data acquisition, data analysis, or a specialized plot type, you typically need to store global variables, strings and waves to maintain the state of your package. You should keep all such items in a data folder that you create with a unique name to reduce clutter and avoid conflicts with other packages.

If your package is inherently global in nature, data acquisition for example, create your data folder within a data folder named Packages that you create (if necessary) in the root data folder. For example:

```
Function MyDAQInit()
   String savDF= GetDataFolder(1)   // Save current DF for restore.

   NewDataFolder/O/S root:Packages     // Make sure this exists.

   if( DataFolderExists("WMDataAcq") ) // Already created WMDataAcq?
      SetDataFolder WMDataAcq          // Our stuff is in here.
      < do reinitialization if necessary >
   else
      NewDataFolder/S WMDataAcq        // Our stuff goes in here.
      Variable/G avar                  // Create at runtime.
      < do other initialization if necessary >
   endif

   SetDataFolder savDF                 // Restore current DF.
End
```

On the other hand, if your package needs to create a group of variables and waves as a result of an operation on a single input wave, it makes sense to create your data folder in the one that holds the input wave (see the **GetWavesDataFolder** function on page V-224). Similarly, if you create a package that takes an entire data folder as input (via a string parameter containing the path to the data folder), does operations on what it finds inside and then needs to create a folder of output, it should create the output data folder in the one, or possibly at the same level as the one containing the input.

If your package creates and maintains windows, it should create a master data folder in root:Packages and then create individual folders within the master that correspond to each instance of a window. For example, a Smith Chart package would create a master data folder as root:Packages:SmithCharts: and then create individual folders inside the master with names that correspond to the individual graphs.

A package designed to operate on traces within graphs would go one step further and create a data folder for each trace that it has worked on, inside the data folder for the graph. This technique is illustrated by the Smooth Control Panel procedure file. For a demonstration, see Examples:Feature Demos:Smoothing Control Panel.pxp.

Storing Runs of Data

If you acquire data using a well-established experimental protocol, your data will have a well-defined structure. Each time you run your protocol, you produce a new data set with the same structure. Storing each data set in its own data folder avoids name conflicts between corresponding items of different data sets. It also simplifies the writing of procedures to analyze and compare data set.

To use a trivial example, your data might have a structure like this:

```
<Run of data>
   String: conditions
   Variable: temperature
   Wave: appliedVoltage
   Wave: luminosity
```

Having defined this structure, you could then write procedures to:

1. Load your data into a data folder
2. Create a graph showing the data from one run
3. Create a graph comparing the data from many runs

Writing these procedures is greatly simplified by the fact that the names of the items in a run are fixed. For example, step 2 could be written as:

```
Function GraphOneRun()  // Graphs data run in the current data folder.
   SVAR conditions
   NVAR temperature
   WAVE appliedVoltage, luminosity

   Display luminosity vs appliedVoltage

   String text
   sprintf text, "Temperature: %g.\rExperimental conditions: %s.",
         temperature, conditions
   Textbox text
End
```

To create a graph, you would first set the current data folder to point to a run of data and then you would invoke the GraphOneRun function.

The Data Folder Tutorial experiment, in the Learning Aids:Tutorials folder, shows in detail how to accomplish the three steps listed above.

Setting and Restoring the Current Data Folder

There are many reasons why you might want to save and restore the current data folder. In this example, we have a function that does a curve fit to a wave passed in as a parameter. The CurveFit operation creates two waves, W_coef and W_sigma, in the current data folder. If you use the /D option, it also creates a destination wave in the current data folder. In this function, we make sure that the W_coef, W_sigma and destination waves are all created in the same data folder as the source wave.

```
Function DoLineFit(w)
   WAVE w

   String dfSav = GetDataFolder(1)
   SetDataFolder GetWavesDataFolder(w,1)
   CurveFit line w /D
   SetDataFolder dfSav
End
```

Many other operations create output waves in the current data folder. Depending on what your goal is, you may want to use the technique shown here to control where the output waves are created.

A function should always save and restore the current data folder unless it is designed explicitly to change the current data folder.

Determining a Function's Target Data Folder

There are three common methods for determining the data folder that a function works on or in:

1. Passing a wave in the target data folder as a parameter
2. Having the function work on the current data folder
3. Passing a string parameter that points to the target data folder

For functions that operate on a specific wave, method 1 is appropriate.

For functions that operation on a large number of variables within a single data folder, methods 2 or 3 are appropriate. In method 2, the calling routine sets the data folder of interest as the current data folder. In method 3, the called function does this, and restores the original current data folder before it returns.

Clearing a Data Folder

There are times when you might want to clear a data folder before running a procedure, to remove things left over from a preceding run. If the data folder contains no child data folders, you can achieve this with:

```
KillWaves/A/Z; KillVariables/A/Z
```

If the data folder does contain child data folders, you could use the KillDataFolder operation. This operation kills a data folder and its contents, including any child data folders. You could kill the main data folder and then recreate it. A problem with this is that, if the data folder or its children contain a wave that is in use, you will generate an error which will cause your function to abort.

Here is a handy function that kills the contents of a data folder and the contents of its children without killing any data folders and without attempting to kill any waves that may be in use.

```
Function ZapDataInFolderTree(path)
   String path

   String savDF= GetDataFolder(1)
   SetDataFolder path

   KillWaves/A/Z
   KillVariables/A/Z
   KillStrings/A/Z

   Variable i
   Variable numDataFolders = CountObjects(":", 4)
   for(i=0; i<numDataFolders; i+=1)
      String nextPath = GetIndexedObjName(":", 4, i)
      ZapDataInFolderTree(nextPath)
   endfor

   SetDataFolder savDF
End
```

Using Strings

This section explains some common ways in which Igor procedures use strings. The most common techniques use built-in functions such as StringFromList and FindListItem. In addition to the built-in functions, there are a number of handy Igor procedure files in the WaveMetrics Procedures:Utilities:String Utilities folder.

Using Strings as Lists

Procedures often need to deal with lists of items. Such lists are usually represented as semicolon-separated text strings. The StringFromList function is used to extract each item, often in a loop. For example:

```
Function Test()
   Make jack,sam,fred,sue
   String list = WaveList("*",";","")
   Print list

   Variable numItems=ItemsInList(list), i
   for(i=0; i<numItems; i+=1)
      Print StringFromList(i,list)     // Print ith item
   endfor
End
```

Using Keyword-Value Packed Strings

A collection of disparate values is often stored in a list of keyword-value pairs. For example, the TraceInfo and AxisInfo functions return such a list. The information in these strings follows this form

```
KEYWORD:value;KEYWORD:value; ...
```

The **keyword** is always upper case and followed by a colon. Then comes the **value** and a semicolon. When parsing such a string, you should avoid reliance on the specific ordering of keywords — the order is likely to change in future releases of Igor.

Two functions will extract information from keyword-value strings. NumberByKey is used when the data is numeric, and StringByKey is used when the information is in the form of text.

Using Strings with Extractable Commands

The **AxisInfo** and **TraceInfo** readback functions provide much of their information in a form that resembles the commands that you use to make the settings in the first place. For example, to set an axis to log mode, you would execute something like this:

```
ModifyGraph log(left)=1
```

If we now look at the characters of the string returned by AxisInfo we see:

```
AXTYPE:left;CWAVE:jack; ... RECREATION:grid(x)=0;log(x)=1 ...
```

To use this information, we need to extract the value following "log(x)=" and then use it in a ModifyGraph command with the extracted value with the desired graph as the target. Here is a user function that sets the log mode of the bottom axis to the same value as the left axis:

```
Function CopyLogMode()
   String info,text
   Variable pos
   info=AxisInfo("","left")
   pos= StrSearch(info,"RECREATION:",0) // skip to start of "RECREATION:"
   pos += strlen("RECREATION:")         // skip "RECREATION:", too
                                        // get text after "log(x)="
   text= StringByKey("log(x)",info[pos,inf],"=",";")

   String cmd = "ModifyGraph log(bottom)=" + text
   Execute cmd
End
```

Regular Expressions

A regular expression is a pattern that is matched against a subject string from left to right. Regular expressions are used to identify lines of text containing a particular pattern and to extracts substrings matching a particular pattern.

A regular expression can contain regular characters that match the same character in the subject and special characters, called "metacharacters", that match any character, a list of specific characters, or otherwise identify patterns.

The regular expression syntax is based on PCRE — the Perl-Compatible Regular Expression Library.

Igor syntax is similar to regular expressions supported by various UNIX and POSIX `egrep(1)` commands. Igor's implementation does not support the Unicode (UTF-8) section of PCRE.

See **Regular Expressions References** on page IV-170 for details on PCRE.

Regular Expression Operations and Functions

Here are the Igor operations and functions that work with regular expressions:

Grep

The **Grep** operation identifies lines of text that match a pattern.

The subject is each line of a file or each row of a text wave or each line of the text in the clipboard.

Output is stored in a file or in a text wave or in the clipboard.

Grep Example

```
Function DemoGrep()
   Make/T source={"Monday","Tuesday","Wednesday","Thursday","Friday"}
   Make/T/N=0 dest
   Grep/E="sday" source as dest           // Find rows containing "sday"
   Print dest
End
```

The output from Print is:

```
   dest[0]= {"Tuesday","Wednesday","Thursday"}
```

GrepList

The **GrepList** function identifies items that match a pattern in a string containing a delimited list.

The subject is each item in the input list.

The output is a delimited list returned as the function result.

GrepList Example

```
Function DemoGrepList()
   String source = "Monday;Tuesday;Wednesday;Thursday;Friday"
   String dest = GrepList(source, "sday") // Find items containing "sday"
   Print dest
End
```

The output from Print is:

```
   Tuesday;Wednesday;Thursday;
```

GrepString

The **GrepString** function determines if a particular pattern exists in the input string.

The subject is the input string.

The output is 1 if the input string contains the pattern or 0 if not.

GrepString Example

```
Function DemoGrepString()
   String subject = "123.45"
   String regExp = "[0-9]+"            // Match one or more digits
   Print GrepString(subject,regExp)    // True if subject contains digit(s)
End
```

The output from Print is: 1

SplitString

The **SplitString** operation identifies subpatterns in the input string.

The subject is the input string.

Output is stored in one or more string output variables.

SplitString Example

```
Function DemoSplitString()
   String subject = "Thursday, May 7, 2009"
   String regExp = "([[:alpha:]]+), ([[:alpha:]]+) ([[:digit:]]+), ([[:digit:]]+)"
   String dayOfWeek, month, dayOfMonth, year
   SplitString /E=(regExp) subject, dayOfWeek, month, dayOfMonth, year
   Print dayOfWeek, month, dayOfMonth, year
End
```

The output from Print is:

```
Thursday  May  7  2009
```

Basic Regular Expressions

Here is a **Grep** command that uses "Fred" as the regular expression. "Fred" contains no metacharacters so this command identifies lines of text containing the literal string "Fred". It examines each line from the input file, afile.txt. All lines containing the pattern "Fred" are written to the output file, "FredFile.txt":

```
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
```

Character matching is case-sensitive by default. Prepending the Perl 5 modifier (?i) gives a case-insensitive pattern that matches upper and lower-case versions of “Fred”:

```
// Copy lines that contain "Fred", "fred", "FRED", "fREd", etc
Grep/P=myPath/E="(?i)fred" "afile.txt" as "AnyFredFile.txt"
```

To copy lines that do not match the regular expression, use the Grep /E flag with the optional *reverse* parameter set to 1 to reverse the sense of the match:

```
// Copy lines that do NOT contain "Fred", "fred", "fREd", etc
Grep/P=myPath/E={"(?i)fred",1} "afile.txt" as "NotFredFile.txt"
```

Note: Igor doesn't use the Perl opening and closing regular expression delimiter character which is the forward slash. In Perl you would use `"/Fred/"` and `"/(?i)fred/"`.

Regular Expression Metacharacters

The power of regular expressions comes from the ability to include alternatives and repetitions in the pattern. These are encoded in the pattern by the use of “metacharacters”, which do not stand for themselves but instead are interpreted in some special way.

There are two different sets of metacharacters: those that are recognized anywhere in the pattern except within brackets, and those that are recognized in brackets. Outside brackets, the metacharacters are as follows:

\	General escape character with several uses
^	Match start of string
$	Match end of string
.	Match any character except newline (by default) (To match newline, see **Matching Newlines** on page IV-161)
[	Start character class definition (for matching one of a set of characters)
|	Start of alternative branch (for matching one or the other of two patterns)
(	Start subpattern
)	End subpattern
?	0 or 1 quantifier (for matching 0 or 1 occurrence of a pattern) Also extends the meaning of (Also quantifier minimizer
*	0 or more quantifier (for matching 0 or more occurrence of a pattern)
+	1 or more quantifier (for matching 1 or more occurrence of a pattern) Also possessive quantifier
{	Start min/max quantifier (for matching a number or range of occurrences)

Character Classes in Regular Expressions

A character class is a set of characters and is used to specify that one character of the set should be matched. Character classes are introduced by a left-bracket and terminated by a right-bracket. For example:

```
[abc]       Matches a or b or c
[A-Z]       Matches any character from A to Z
[A-Za-z]    Matches any character from A to Z or a to z.
```

POSIX character classes specify the characters to be matched symbolically. For example:

```
[[:alpha:]] Matches any alphabetic character (A to Z or a to z).
[[:digit:]] Matches 0 to 9.
```

In a character class the only metacharacters are:

\	General escape character
^	Negate the class, but only if ^ is the first character
-	Indicates character range
[	POSIX character class (only if followed by POSIX syntax)
]	Terminates the character class

Backslash in Regular Expressions

The backslash character has several uses. First, if it is followed by a nonalphanumeric character, it takes away any special meaning that character may have. This use of backslash as an escape character applies both inside and outside character classes.

For example, the * character normally means "match zero or more of the preceding subpattern". If you want to match a * character, you write * in the pattern. This escaping action applies whether or not the following character would otherwise be interpreted as a metacharacter, so it is always safe to precede a nonalphanumeric with backslash to specify that it stands for itself. In particular, if you want to match a backslash, you write \\.

Note: Because Igor also has special uses for backslash (see **Escape Characters in Strings** on page IV-13), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes sends one backslash to, say, the **Grep** command.

For example, to copy lines that contain a backslash followed by a *z* character, the Perl pattern would be "\\z", but the equivalent Igor Grep expression would be /E="\\\\z".

Igor's input string parser converts "\\" to "\" so, when you write /E="\\\\z", the regular expression engine sees /E="\\z".

This difference is important enough that the PCRE and Igor Patterns (using Grep /E syntax) are both shown below when they differ.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between \Q and \E. This is different from Perl in that $ and @ are handled as literals in \Q...\E sequences in PCRE, whereas in Perl, $ and @ cause variable interpolation. Note the following examples:

Igor Pattern	PCRE Pattern	PCRE Matches	Perl Matches
\\Qabc$xyz\\E	\Qabc$xyz\E	abc$xyz	abc followed by the contents of $xyz
\\Qabc\\$xyz\\E	\Qabc\$xyz\E	abc\$xyz	abc\$xyz
\\Qabc\\E\\$\\Qxyz\\E	\Qabc\E\$\Qxyz\E	abc$xyz	abc$xyz

The \Q...\E sequence is recognized both inside and outside character classes.

Backslash and Nonprinting Characters

A second use of backslash provides a way of encoding nonprinting characters in patterns in a visible manner. There is no restriction on where nonprinting characters can occur, apart from the binary zero that terminates a pattern, but when a pattern is being prepared by text editing, it is usually easier to use one of the following escape sequences than the binary character it represents:

Igor Pattern	PCRE Pattern	Character Matched
\\a	\a	Alarm, that is, the BEL character (hex 07)
\\cx	\cx	“Control-x”, where x is any character
\\e	\e	Escape (hex 1B)
\\f	\f	Formfeed (hex 0C)
\\n	\n	Newline (hex 0A)
\\r	\r	Carriage return (hex 0D)
\\t	\t	Tab (hex 09)
\\ddd	\ddd	Character with octal code ddd, or backreference
\\xhh	\xhh	Character with hex code hh

Backslash and Nonprinting Characters Arcania

The material in this section is arcane and rarely needed. We recommend that you skip it.

The precise effect of \cx is if x is a lower case letter, it is converted to upper case. Then bit 6 of the character (hex 40) is inverted. Thus \cz becomes hex 1A, but \c{ becomes hex 3B, while \c; becomes hex 7B.

After \x, from zero to two hexadecimal digits are read (letters can be in upper or lower case). If characters other than hexadecimal digits appear between \x{ and }, or if there is no terminating }, this form of escape is not recognized. Instead, the initial \x will be interpreted as a basic hexadecimal escape, with no following digits, giving a character whose value is zero.

After \0 up to two further octal digits are read. In both cases, if there are fewer than two digits, just those that are present are used. Thus the sequence \0\x\07 specifies two binary zeros followed by a BEL character (code value 7). Make sure you supply two digits after the initial zero if the pattern character that follows is itself an octal digit.

The handling of a backslash followed by a digit other than 0 is complicated. Outside a character class, PCRE reads it and any following digits as a decimal number. If the number is less than 10, or if there have been at least that many previous capturing left parentheses in the expression, the entire sequence is taken as a back reference. A description of how this works is given later, following the discussion of parenthesized subpatterns.

Inside a character class, or if the decimal number is greater than 9 and there have not been that many capturing subpatterns, PCRE rereads up to three octal digits following the backslash, and generates a single byte from the least significant 8 bits of the value. Any subsequent digits stand for themselves. For example:

Igor Pattern	PCRE Pattern	Character(s) Matched
\\040	\040	Another way of writing a space
\\40	\40	A space, provided there are fewer than 40 previous capturing subpatterns
\\7	\7	Always a back reference
\\11	\11	Might be a back reference, or another way of writing a tab
\\011	\011	Always a tab
\\0113	\0113	A tab followed by the character “3”
\\113	\113	Might be a back reference, otherwise the character with octal code 113
\\377	\377	Might be a back reference, otherwise the byte consisting entirely of 1 bits
\\81	\81	Either a back reference or a binary zero followed by the two characters “8” and “1”

Note that octal values of 100 or greater must not be introduced by a leading zero, because no more than three octal digits are ever read.

All the sequences that define a single byte value can be used both inside and outside character classes. In addition, inside a character class, the sequence \b is interpreted as the backspace character (hex 08), and the sequence \X is interpreted as the character X. Outside a character class, these sequences have different meanings (see **Backslash and Nonprinting Characters** on page IV-156).

Backslash and Generic Character Types

The third use of backslash is for specifying generic character types. The following are always recognized:

Igor Pattern	PCRE Pattern	Character(s) Matched
\\d	\d	Any decimal digit
\\D	\D	Any character that is not a decimal digit
\\s	\s	Any whitespace character
\\S	\S	Any character that is not a whitespace character
\\w	\w	Any “word” character
\\S	\W	Any “nonword” character

Each pair of escape sequences, such as \d and \D, partitions the complete set of characters into two disjoint sets. Any given character matches one, and only one, of each pair.

These character type sequences can appear both inside and outside character classes. They each match one character of the appropriate type. If the current matching point is at the end of the subject string, all of them fail, since there is no character to match.

For compatibility with Perl, \s does not match the vertical tab character (VT-ASCII code 11). This makes it different from the POSIX "space" class. The \s whitespace characters are horizontal tab (HT-9), linefeed (LF-10), formfeed (FF-12), carriage-return (CR-13), and space (32).

A “word” character is an underscore or any character that is a letter or digit.

Backslash and Simple Assertions

The fourth use of backslash is for certain simple assertions. An assertion specifies a condition that has to be met at a particular point in a match without consuming any characters from the subject string. The use of subpatterns for more complicated assertions is described in **Assertions** on page IV-166. The backslashed assertions are:

Igor Pattern	PCRE Pattern	Character(s) Matched
\\b	\b	At a word boundary
\\B	\B	Not at a word boundary
\\A	\A	At start of subject
\\Z	\Z	At end of subject or before newline at end
\\z	\z	At end of subject
\\G	\G	At first matching position in subject

These assertions may not appear in character classes (but note that \b has a different meaning, namely the backspace character, inside a character class).

A word boundary is a position in the subject string where the current character and the previous character do not both match \w or \W (i.e. one matches \w and the other matches \W), or the start or end of the string if the first or last character matches \w, respectively.

While PCRE defines additional simple assertions (\A, \Z, \z and \G), they are not any more useful to Igor’s regular expression commands than the ^ and $ characters.

Circumflex and Dollar

Outside a character class, in the default matching mode, the circumflex character ^ is an assertion that is true only if the current matching point is at the start of the subject string. Inside a character class, circumflex has an entirely different meaning (see **Character Classes and Brackets** on page IV-159).

Circumflex need not be the first character of the pattern if a number of alternatives are involved, but it should be the first thing in each alternative in which it appears if the pattern is ever to match that branch. If all possible alternatives start with a circumflex, that is, if the pattern is constrained to match only at the start of the subject, it is said to be an “anchored” pattern. (There are also other constructs that can cause a pattern to be anchored.)

A dollar character $ is an assertion that is true only if the current matching point is at the end of the subject string, or immediately before a newline character that is the last character in the string (by default). Dollar need not be the last character of the pattern if a number of alternatives are involved, but it should be the last item in any branch in which it appears. Dollar has no special meaning in a character class.

Dot, Period, or Full Stop

Outside a character class, a dot in the pattern matches any one character in the subject, including a nonprinting character, but not (by default) newline. Dot has no special meaning in a character class.

The match option setting (?s) changes the default behavior of dot so that it matches any character including newline. The setting can appear anywhere before the dot in the pattern. See **Matching Newlines** on page IV-161 for details.

Character Classes and Brackets

An opening bracket introduces a character class which is terminated by a closing bracket. A closing bracket on its own is not special. If a closing bracket is required as a member of the class, it must be the first data character in the class (after an initial circumflex, if present) or escaped with a backslash.

A character class matches a single character in the subject. A matched character must be in the set of characters defined by the class, unless the first character in the class definition is a circumflex, in which case the subject character must not be in the set defined by the class. If a circumflex is actually required as a member of the class, ensure it is not the first character, or escape it with a backslash.

For example, the character class `[aeiou]` matches any English lower case vowel, whereas `[^aeiou]` matches any character that is not an English lower case vowel. Note that a circumflex is just a convenient notation for specifying the characters that are in the class by enumerating those that are not.

When caseless matching is set, using the `(?i)` match option setting, any letters in a class represent both their upper case and lower case versions, so for example, the caseless pattern `(?i)[aeiou]` matches *A* as well as *a*, and the caseless pattern `(?i)[^aeiou]` does not match *A*.

The minus (hyphen) character can be used to specify a range of characters in a character class. For example, `[d-m]` matches any letter between *d* and *m*, inclusive. If a minus character is required in a class, it must be escaped with a backslash or appear in a position where it cannot be interpreted as indicating a range, typically as the first or last character in the class.

To include a right-bracket in a range you must use `\]`. As usual, this would be represented in a literal Igor string as `\\]`.

Though it is rarely needed, you can specify a range using octal numbers, for example `[\000-\037]`.

The character types `\d`, `\D`, `\p`, `\P`, `\s`, `\S`, `\w`, and `\W` may also appear in a character class, and add the characters that they match to the class. For example, `[\dABCDEF]` matches any hexadecimal digit. A circumflex can conveniently be used with the upper case character types to specify a more restricted set of characters than the matching lower case type. For example, the class `[^\W_]` matches any letter or digit, but not underscore. The corresponding **Grep** command would begin with

```
Grep/E="[^\\W_]"…
```

The only metacharacters that are recognized in character classes are backslash, hyphen (only where it can be interpreted as specifying a range), circumflex (only at the start), opening bracket (only when it can be interpreted as introducing a POSIX class name — see **POSIX Character Classes** on page IV-159), and the terminating closing bracket. However, escaping other nonalphanumeric characters does no harm.

POSIX Character Classes

Perl supports the POSIX notation for character classes. This uses names enclosed by `[:` and `:]` within the enclosing brackets. PCRE also supports this notation. For example,

```
[01[:alpha:]%]
```

matches “0”, “1”, any alphabetic character, or “%”.

The supported class names, all of which must appear between `[:` and `:]` inside a character class specification, are

`alnum`	Letters and digits
`alpha`	Letters
`ascii`	Character codes 0 - 127

blank	Space or tab only
cntrl	Control characters
digit	Decimal digits (same as \d)
graph	Printing characters, excluding space
lower	Lower case letters
print	Printing characters, including space
punct	Printing characters, excluding letters and digits
space	White space (not quite the same as \s)
upper	Upper case letters
word	"Word" characters (same as \w)
xdigit	Hexadecimal digits

The "space" characters are horizontal tab (HT-9), linefeed (LF-10), vertical tab (VT-11), formfeed (FF-12), carriage-return (CR-13), and space (32). Notice that this list includes the VT character (code 11). This makes "space" different from \s, which does not include VT (for Perl compatibility).

The class name word is a Perl extension, and blank is a GNU extension from Perl 5.8. Another Perl extension is negation that is indicated by a ^ character after the colon. For example,

```
[12[:^digit:]]
```

matches "1", "2", or any nondigit. PCRE (and Perl) also recognize the POSIX syntax [.ch.] and [=ch=] where "ch" is a "collating element", but these are not supported, and an error is given if they are encountered.

Alternation

Vertical bar characters are used to separate alternative patterns. For example, the pattern

```
gilbert|sullivan
```

matches either "gilbert" or "sullivan". Any number of alternative patterns may be specified, and an empty alternative is permitted (matching the empty string). The matching process tries each alternative in turn, from left to right, and the first one that succeeds is used. If the alternatives are within a subpattern (defined in **Subpatterns** on page IV-162), "succeeds" means matching the rest of the main pattern as well as the alternative in the subpattern.

Match Option Settings

Character matching options can be changed from within the pattern by a sequence of Perl option letters enclosed between (? and). The option letters are:

Option	PCRE Name	Characters Matched
i	PCRE_CASELESS	Upper and lower case.
m	PCRE_MULTILINE	^ matches start of string and just after a new line (\n). $ matches end of string and just before a new line. Without (?m), ^ and $ match only the start and end of the entire string.
s	PCRE_DOTALL	. matches all characters including newline. Without (?s), . does not match newlines. See **Matching Newlines** on page IV-161.
U	PCRE_UNGREEDY	Reverses the "greediness" of the quantifiers so that they are not greedy by default, but become greedy if followed by ?.

For example, (?i) sets caseless matching.

You can unset these options by preceding the letter with a hyphen: (?-i) turns off caseless matching.

You can combine a setting and unsetting such as `(?i-U)`, which sets PCRE_CASELESS while unsetting PCRE_UNGREEDY.

When an option change occurs at top level (that is, not inside subpattern parentheses), the change applies to the remainder of the pattern that follows. If the change is placed right at the start of a pattern, PCRE extracts it into the global options.

An option change within a subpattern affects only that part of the current pattern that follows it, so

```
(a(?i)b)c
```

matches abc and aBc and no other strings.

Any changes made in one alternative do carry on into subsequent branches within the same subpattern. For example,

```
(a(?i)b|c)
```

matches “ab”, “aB”, “c”, and “C”, even though when matching “C” the first branch is abandoned before the option setting. This is because the effects of option settings happen at compile time.

The other PCRE 5-specific options, such as (?e), (?A), (?D), (?S), (?x) and (?X), are implemented but are not very useful with Igor's regular expression commands.

Matching Newlines

Igor generally uses carriage-return (ASCII code 13) return to indicate a new line in text. This is represented in a literal string by "\r". For example:

```
Print "Hello\rGoodbye"
```

prints two lines of text to the history area.

However, in regular expressions, the newline character is linefeed (ASCII code 10). This is represented in a literal string by "\n". Carriage-return has no special status in regular expressions.

The match option setting `(?s)` changes the default behavior of dot so that it matches any character including newline. The setting can appear anywhere before the dot in the pattern. For example:

```
Function DemoNewline(includeNewline)
   Variable includeNewline

   String subject = "Hello\nGoodbye"   // \n represents newline

   String regExp
   if (includeNewline)
      regExp = "(?s)(.+)"     // One or more of any character
   else
      regExp = "(.+)"         // One or more of any character except newline
   endif

   String result
   SplitString /E=(regExp) subject, result
   Print result
End
```

The output from DemoNewline(0) is:

```
Hello
```

The output from DemoNewline(1) is:

```
Hello\nGoodbye
```

Here is a more realistic example:

```
Function DemoDotAll()
   String theString = ExampleHTMLString()

   // This regular expression attempts to extract items from
   // HTML code for an ordered list. It fails because the HTML
   // code contains newlines and, by default, . does not match newlines.
   String regExpFails="<li>(.*?)</li>.*<li>(.*?)</li>"
   String str1, str2
   SplitString/E=regExpFails theString, str1, str2
   Print V_flag, " subpatterns were matched using regExpFails"
   Printf "\"%s\", \"%s\"\r", str1, str2

   // This regular expression works because the "(?s)" match
   // option setting causes . to match newlines.
   String regExpWorks="(?s)<li>(.*?)</li>.*<li>(.*?)</li>"
   SplitString/E=regExpWorks theString, str1, str2
   Print V_flag, " subpatterns were matched using regExpWorks"
   Printf "\"%s\", \"%s\"\r", str1, str2
End
Function/S ExampleHTMLString()   // Returns HTML code containing newlines
   String theString = ""
   theString += "<ol>\n"
   theString += "\t<li>item 1</li>\n"
   theString += "\t<li>item 2</li>\n"
   theString += "<\ol>\n"
   return theString
End

•DemoDotAll()
  0   subpatterns were matched using regExpFails
  "", ""
  2 subpatterns were matched using regExpWorks
  "item 1", "item 2"
```

Subpatterns

Subpatterns are used to group alternatives, to match a previously-matched pattern again, and to extract match text using **SplitString**.

Subpatterns are delimited by parentheses, which can be nested. Turning part of a pattern into a subpattern localizes a set of alternatives. For example, this pattern (which includes two vertical bars signifying alternation):

```
cat(aract|erpillar|)
```

matches one of the words "cat", "cataract", or "caterpillar". Without the parentheses, it would match "cataract", "erpillar" or the empty string.

Named Subpatterns

Specifying subpatterns by number is simple, but it can be very hard to keep track of the numbers in complicated regular expressions. Furthermore, if an expression is modified, the numbers may change. To help with this difficulty, PCRE supports the naming of subpatterns, something that Perl does not provide. The Python syntax (`?P<`*name*`>`...) is used. For example:

```
My (?P<catdog>cat|dog) is cooler than your (?P=catdog)
```

Here catdog is the name of the first and only subpattern. `?P<catdog>` names the subpattern and `(?P=catdog)` matches the previous match for that subpattern.

Names consist of alphanumeric characters and underscores, and must be unique within a pattern.

Named capturing parentheses are still allocated numbers as well as names. This has the same effect as the previous example:

```
My (?P<catdog>cat|dog) is cooler than your \\1
```

Repetition

Repetition is specified by quantifiers:

?	0 or 1 quantifier
	Example: `[abc]?` - Matches 0 or 1 occurrences of a or b or c
*	0 or more quantifier
	Example: `[abc]*` - Matches 0 or more occurrences of a or b or c
+	1 or more quantifier
	Example: `[abc]+` - Matches 1 or more occurrences of a or b or c
{n}	n times quantifier
	Example: `[abc]{3}` - Matches 3 occurrences of a or b or c
{n,m}	n to m times quantifier
	Example: `[abc]{3,5}` - Matches 3 to 5 occurrences of a or b or c

Quantifiers can follow any of the following items:

- A literal data character
- The . metacharacter
- The \C escape sequence
- An escape such as \d that matches a single character
- A character class
- A back reference (see **Back References** on page IV-166)
- A parenthesized subpattern (unless it is an assertion)

The general repetition quantifier specifies a minimum and maximum number of permitted matches, by giving the two numbers in braces, separated by a comma. The numbers must be less than 65536, and the first must be less than or equal to the second. For example:

```
z{2,4}
```

matches “zz”, “zzz”, or “zzzz”.

If the second number is omitted, but the comma is present, there is no upper limit; if the second number and the comma are both omitted, the quantifier specifies an exact number of required matches. Thus

```
[aeiou]{3,}
```

matches at least 3 successive vowels, but may match many more, while

```
\d{8}
```

matches exactly 8 digits. A left brace that appears in a position where a quantifier is not allowed, or one that does not match the syntax of a quantifier, is taken as a literal character. For example, `{,6}` is not a quantifier, but a literal string of four characters.

The quantifier `{0}` is permitted, causing the expression to behave as if the previous item and the quantifier were not present.

For convenience (and historical compatibility) the three most common quantifiers have single-character abbreviations:

`*`	Equivalent to `{0,}`
`+`	Equivalent to `{1,}`
`?`	Equivalent to `{0,1}`

It is possible to construct infinite loops by following a subpattern that can match no characters with a quantifier that has no upper limit, for example:

```
(a?)*
```

Earlier versions of Perl and PCRE used to give an error at compile time for such patterns. However, because there are cases where this can be useful, such patterns are now accepted, but if any repetition of the subpattern does in fact match no characters, the loop is forcibly broken.

Quantifier Greediness

By default, the quantifiers are "greedy", that is, they match as much as possible (up to the maximum number of permitted times), without causing the rest of the pattern to fail. The classic example of where this gives problems is in trying to match comments in C programs. These appear between `/*` and `*/` and within the comment, individual `*` and `/` characters may appear. An attempt to match C comments by applying the pattern

```
/\*.*\*/        or    Grep/E="/\\*.*\\*/"
```

to the string

```
/* first comment */  not comment  /* second comment */
```

fails because it matches the entire string owing to the greediness of the `.*` item.

However, if a quantifier is followed by a question mark, it ceases to be greedy, and instead matches the minimum number of times possible, so the pattern

```
/\*.*?\*/       or    Grep/E="/\\*.*?\\*/"
```

does the right thing with the C comments. The meaning of the various quantifiers is not otherwise changed, just the preferred number of matches.

Do not confuse this use of question mark with its use as a quantifier in its own right. Because it has two uses, it can sometimes appear doubled, as in

```
\d??\d          or    Grep/E="\\d??\\d"
```

which matches one digit by preference, but can match two if that is the only way the rest of the pattern matches.

If the PCRE_UNGREEDY option `(?U)` is set, the quantifiers are not greedy by default, but individual ones can be made greedy by following them with a question mark. In other words, it inverts the default behavior.

Quantifiers With Subpatterns

When a parenthesized subpattern is quantified with a minimum repeat count that is greater than 1 or with a limited maximum, more memory is required for the compiled pattern, in proportion to the size of the minimum or maximum.

When a capturing subpattern is repeated, the value captured is the substring that matched the final iteration. For example, after

```
(tweedle[dume]{3}\s*)+  or    Grep/E="(tweedle[dume]{3}\\s*)+"
```

has matched "tweedledum tweedledee" the value of the captured substring is "tweedledee". However, if there are nested capturing subpatterns, the corresponding captured values may have been set in previous iterations. For example, after

```
/(a|(b))+/
```

matches "aba" the value of the second captured substring is "b".

Atomic Grouping and Possessive Quantifiers

With both maximizing and minimizing repetition, failure of what follows normally reevaluates the repeated item to see if a different number of repeats allows the rest of the pattern to match. Sometimes it is useful to prevent this, either to change the nature of the match, or to cause it fail earlier than it otherwise might, when the author of the pattern knows there is no point in carrying on.

Consider, for example, the pattern `\d+foo` when applied to the subject line

```
123456bar
```

After matching all 6 digits and then failing to match "foo", the normal action of the matcher is to try again with only 5 digits matching the `\d+` item, and then with 4, and so on, before ultimately failing. "Atomic grouping" provides the means for specifying that once a subpattern has matched, it is not to be reevaluated in this way.

If we use atomic grouping for the previous example, the matcher would give up immediately on failing to match "foo" the first time. The notation is a kind of special parenthesis, starting with `(?>` as in this example:

```
(?>\d+)foo      or    Grep/E="(?>\\d+)foo"
```

This kind of parenthesis "locks up" the part of the pattern it contains once it has matched, and a failure further into the pattern is prevented from backtracking into it. Backtracking past it to previous items, however, works as normal.

An alternative description is that a subpattern of this type matches the string of characters that an identical standalone pattern would match, if anchored at the current point in the subject string.

Atomic grouping subpatterns are not capturing subpatterns. Simple cases such as the above example can be thought of as a maximizing repeat that must swallow everything it can. So, while both `\d+` and `\d+?` are prepared to adjust the number of digits they match in order to make the rest of the pattern match, `(?>\d+)` can only match an entire sequence of digits.

Atomic groups in general can of course contain arbitrarily complicated subpatterns, and can be nested. However, when the subpattern for an atomic group is just a single repeated item, as in the example above, a simpler notation, called a "possessive quantifier" can be used. This consists of an additional `+` character following a quantifier. Using this notation, the previous example can be rewritten as

```
\d++foo         or    Grep/E="\\d++foo"
```

Possessive quantifiers are always greedy; the setting of the PCRE_UNGREEDY option is ignored. They are a convenient notation for the simpler forms of atomic group. However, there is no difference in the meaning or processing of a possessive quantifier and the equivalent atomic group.

The possessive quantifier syntax is an extension to the Perl syntax. It originates in Sun's Java package.

When a pattern contains an unlimited repeat inside a subpattern that can itself be repeated an unlimited number of times, the use of an atomic group is the only way to avoid some failing matches taking a very long time indeed. The pattern

```
(\D+|<\d+>)*[!?]   or    Grep/E="(\\D+|<\\d+>)*[!?]"
```

matches an unlimited number of substrings that either consist of nondigits, or digits enclosed in `<>`, followed by either `!` or `?`. When it matches, it runs quickly. However, if it is applied to

```
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
```

it takes a long time before reporting failure. This is because the string can be divided between the internal `\D+` repeat and the external `*` repeat in a large number of ways, and all have to be tried. (The example uses `[!?]` rather than a single character at the end, because both PCRE and Perl have an optimization that allows for fast failure when a single character is used. They remember the last single character that is required for a match, and fail early if it is not present in the string.) If the pattern is changed so that it uses an atomic group, like this:

```
((?>\D+)|<\d+>)*[!?]    or    Grep/E="((?>\\D+)|<\\d+>)*[!?]"
```

sequences of nondigits cannot be broken, and failure happens quickly.

Back References

Outside a character class, a backslash followed by a digit greater than 0 (and possibly further digits) is a back reference to a capturing subpattern earlier (that is, to its left) in the pattern, provided there have been that many previous capturing left parentheses.

However, if the decimal number following the backslash is less than 10, it is always taken as a back reference, and causes an error only if there are not that many capturing left parentheses in the entire pattern. In other words, the parentheses that are referenced need not be to the left of the reference for numbers less than 10. See **Backslash and Nonprinting Characters** on page IV-156 for further details of the handling of digits following a backslash.

A back reference matches whatever actually matched the capturing subpattern in the current subject string, rather than anything matching the subpattern itself (see **Subpatterns as Subroutines** on page IV-170 for a way of doing that). So the pattern

```
(sens|respons)e and \1ibility or /E="(sens|respons)e and \\1ibility"
```

matches "sense and sensibility" and "response and responsibility", but not "sense and responsibility". If caseful matching is in force at the time of the back reference, the case of letters is relevant. For example,

```
((?i)rah)\s+\1     or     Grep/E="((?i)rah)\\s+\\1"
```

matches "rah rah" and "RAH RAH", but not "RAH rah", even though the original capturing subpattern is matched caselessly.

Back references to named subpatterns use the Python syntax `(?P<name>)`. We could rewrite the above example as follows:

```
(?P<p1>(?i)rah)\s+(?P=p1)   or     Grep/E="(?P<p1>(?i)rah)\\s+(?P=p1)"
```

There may be more than one back reference to the same subpattern. If a subpattern has not actually been used in a particular match, any back references to it always fail. For example, the pattern

```
(a|(bc))\2
```

always fails if it starts to match "a" rather than "bc". Because there may be many capturing parentheses in a pattern, all digits following the backslash are taken as part of a potential back reference number. If the pattern continues with a digit character, some delimiter must be used to terminate the back reference. An empty comment (see **Regular Expression Comments** on page IV-169) can be used.

A back reference that occurs inside the parentheses to which it refers fails when the subpattern is first used, so, for example, `(a\1)` never matches. However, such references can be useful inside repeated subpatterns. For example, the pattern

```
(a|b\1)+        or     Grep/E="(a|b\\1)+"
```

matches any number of *a*'s and also "aba", "ababbaa" etc. At each iteration of the subpattern, the back reference matches the character string corresponding to the previous iteration. In order for this to work, the pattern must be such that the first iteration does not need to match the back reference. This can be done using alternation, as in the example above, or by a quantifier with a minimum of zero.

Assertions

An assertion is a test on the characters following or preceding the current matching point that does not actually consume any characters. The simple assertions coded as `\b`, `\B`, `^` and `$` are described in **Backslash and Simple Assertions** on page IV-158.

More complicated assertions are coded as subpatterns. There are two kinds: those that look ahead of the current position in the subject string, and those that look behind it. An assertion subpattern is matched in the normal way, except that it does not cause the current matching position to be changed.

Assertion subpatterns are not capturing subpatterns, and may not be repeated, because it makes no sense to assert the same thing several times. If any kind of assertion contains capturing subpatterns within it, these are counted for the purposes of numbering the capturing subpatterns in the whole pattern. However, substring capturing is carried out only for positive assertions, because it does not make sense for negative assertions.

Lookahead Assertions

Lookahead assertions start with (?= for positive assertions and (?! for negative assertions. For example,

```
\w+(?=;)        or    Grep/E="\\w+(?=;)"
```

matches a word followed by a semicolon, but does not include the semicolon in the match, and

```
foo(?!bar)
```

matches any occurrence of "foo" that is not followed by "bar". Note that the apparently similar pattern

```
(?!foo)bar
```

does not find an occurrence of "bar" that is preceded by something other than "foo"; it finds any occurrence of "bar" whatsoever, because the assertion (?!foo) is always true when the next three characters are "bar". A lookbehind assertion is needed to achieve the other effect.

If you want to force a matching failure at some point in a pattern, the most convenient way to do it is with (?!) because an empty string always matches, so an assertion that requires there not to be an empty string must always fail.

Lookbehind Assertions

Lookbehind assertions start with (?<= for positive assertions and (?<! for negative assertions. For example,

```
(?<!foo)bar
```

does find an occurrence of "bar" that is not preceded by "foo". The contents of a lookbehind assertion are restricted such that all the strings it matches must have a fixed length. However, if there are several alternatives, they do not all have to have the same fixed length. Thus

```
(?<=bullock|donkey)
```

is permitted, but

```
(?<!dogs?|cats?)
```

causes an error at compile time. Branches that match different length strings are permitted only at the top level of a lookbehind assertion. This is an extension compared with Perl (at least for 5.8), which requires all branches to match the same length of string. An assertion such as

```
(?<=ab(c|de))
```

is not permitted, because its single top-level branch can match two different lengths, but it is acceptable if rewritten to use two top-level branches:

```
(?<=abc|abde)
```

The implementation of lookbehind assertions is, for each alternative, to temporarily move the current position back by the fixed width and then try to match. If there are insufficient characters before the current position, the match is deemed to fail.

Atomic groups can be used in conjunction with lookbehind assertions to specify efficient matching at the end of the subject string. Consider a simple pattern such as

```
abcd$
```

when applied to a long string that does not match. Because matching proceeds from left to right, PCRE will look for each *a* in the subject and then see if what follows matches the rest of the pattern. If the pattern is specified as

```
^.*abcd$
```

the initial .* matches the entire string at first, but when this fails (because there is no following *a*), it backtracks to match all but the last character, then all but the last two characters, and so on. Once again the search for *a* covers the entire string, from right to left, so we are no better off. However, if the pattern is written as

```
^(?>.*)(?<=abcd)
```

or, equivalently, using the possessive quantifier syntax,

```
^.*+(?<=abcd)
```

there can be no backtracking for the .* item; it can match only the entire string. The subsequent lookbehind assertion does a single test on the last four characters. If it fails, the match fails immediately. For long strings, this approach makes a significant difference to the processing time.

Using Multiple Assertions

Several assertions (of any sort) may occur in succession. For example,

```
(?<=\d{3})(?<!999)foo    or     Grep/E="(?<=\\d{3})(?<!999)foo"
```

matches "foo" preceded by three digits that are not "999". Notice that each of the assertions is applied independently at the same point in the subject string. First there is a check that the previous three characters are all digits, and then there is a check that the same three characters are not "999". This pattern does not match "foo" preceded by six characters, the first of which are digits and the last three of which are not "999". For example, it doesn't match "123abcfoo". A pattern to do that is

```
(?<=\d{3}...)(?<!999)foo or     Grep/E="(?<=\\d{3}...)(?<!999)foo"
```

This time the first assertion looks at the preceding six characters, checking that the first three are digits, and then the second assertion checks that the preceding three characters are not "999".

Assertions can be nested in any combination. For example,

```
(?<=(?<!foo)bar)baz
```

matches an occurrence of "baz" that is preceded by "bar" which in turn is not preceded by "foo", while

```
(?<=\d{3}(?!999)...)foo or Grep/E=" (?<=\\d{3}(?!999)...)foo"
```

is another pattern that matches "foo" preceded by three digits and any three characters that are not "999".

Conditional Subpatterns

It is possible to cause the matching process to obey a subpattern conditionally or to choose between two alternative subpatterns, depending on the result of an assertion, or whether a previous capturing subpattern matched or not. The two possible forms of conditional subpattern are

```
(?(condition)yes-pattern)
(?(condition)yes-pattern|no-pattern)
```

If the condition is satisfied, the yes-pattern is used; otherwise the no-pattern (if present) is used. If there are more than two alternatives in the subpattern, a compile-time error occurs.

There are three kinds of condition. If the text between the parentheses consists of a sequence of digits, the condition is satisfied if the capturing subpattern of that number has previously matched. The number must be greater than zero. Consider the following pattern, which contains nonsignificant white space to make it more readable and to divide it into three parts for ease of discussion:

```
( \( )?    [^()]+    (?(1) \) )
```

The first part matches an optional opening parenthesis, and if that character is present, sets it as the first captured substring. The second part matches one or more characters that are not parentheses. The third part is a conditional subpattern that tests whether the first set of parentheses matched or not. If they did, that is, if subject started with an opening parenthesis, the condition is true, and so the yes-pattern is executed and a closing parenthesis is required. Otherwise, since no-pattern is not present, the subpattern matches nothing. In other words, this pattern matches a sequence of nonparentheses, optionally enclosed in parentheses.

If the condition is the string (R), it is satisfied if a recursive call to the pattern or subpattern has been made. At "top level", the condition is false. This is a PCRE extension. Recursive patterns are described in the next section.

If the condition is not a sequence of digits or (R), it must be an assertion. This may be a positive or negative lookahead or lookbehind assertion. Consider this pattern, again containing nonsignificant white space, and with the two alternatives on the second line:

```
(?(?=[^a-z]*[a-z])
\d{2}-[a-z]{3}-\d{2}  |  \d{2}-\d{2}-\d{2})
```

The condition is a positive lookahead assertion that matches an optional sequence of nonletters followed by a letter. In other words, it tests for the presence of at least one letter in the subject. If a letter is found, the subject is matched against the first alternative; otherwise it is matched against the second. This pattern matches strings in one of the two forms dd-aaa-dd or dd-dd-dd, where aaa are letters and dd are digits.

Regular Expression Comments

The sequence (?# marks the start of a comment that continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part in the pattern matching at all.

Recursive Patterns

Consider the problem of matching a string in parentheses, allowing for unlimited nested parentheses. Without the use of recursion, the best that can be done is to use a pattern that matches up to some fixed depth of nesting. It is not possible to handle an arbitrary nesting depth. Perl provides a facility that allows regular expressions to recurse (amongst other things). It does this by interpolating Perl code in the expression at runtime, and the code can refer to the expression itself. A Perl pattern to solve the parentheses problem can be created like this:

```
$re = qr{\( (?: (?>[^()]+) | (?p{$re}) )* \)}x;
```

The (?p{...}) item interpolates Perl code at runtime, and in this case refers recursively to the pattern in which it appears. Obviously, PCRE cannot support the interpolation of Perl code. Instead, it supports some special syntax for recursion of the entire pattern, and also for individual subpattern recursion.

The special item that consists of (? followed by a number greater than zero and a closing parenthesis is a recursive call of the subpattern of the given number, provided that it occurs inside that subpattern. (If not, it is a "subroutine" call, which is described in **Subpatterns as Subroutines** on page IV-170.) The special item (?R) is a recursive call of the entire regular expression.

For example, this PCRE pattern solves the nested parentheses problem (additional nonfunction whitespace has been added to separate the expression into parts):

```
\( ( (?>[^()]+) | (?R) )* \)
```

First it matches an opening parenthesis. Then it matches any number of substrings which can either be a sequence of nonparentheses, or a recursive match of the pattern itself (that is a correctly parenthesized substring). Finally there is a closing parenthesis.

If this were part of a larger pattern, you would not want to recurse the entire pattern, so instead you could use this:

```
( \( ( (?>[^()]+) | (?1) )* \))
```

We have put the pattern into parentheses, and caused the recursion to refer to them instead of the whole pattern. In a larger pattern, keeping track of parenthesis numbers can be tricky. It may be more convenient to use named parentheses instead. For this, PCRE uses (?P>name), which is an extension to the Python syntax that PCRE uses for named parentheses (Perl does not provide named parentheses). We could rewrite the above example as follows:

```
(?P<pn> \( ( (?>[^()]+) | (?P>pn) )* \))
```

This particular example pattern contains nested unlimited repeats, and so the use of atomic grouping for matching strings of nonparentheses is important when applying the pattern to strings that do not match. For example, when this pattern is applied to

```
(aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa()
```

it yields "no match" quickly. However, if atomic grouping is not used, the match runs for a very long time indeed because there are so many different ways the + and * repeats can carve up the subject, and all have to be tested before failure can be reported.

At the end of a match, the values set for any capturing subpatterns are those from the outermost level of the recursion at which the subpattern value is set. If you want to obtain intermediate values, a callout function can be used (see **Subpatterns as Subroutines** on page IV-170). If the pattern above is matched against

```
(ab(cd)ef)
```

the value for the capturing parentheses is "ef", which is the last value taken on at the top level. If additional parentheses are added, giving

```
\(( ( (?>[^()]+) | (?R) )* ) \)
     ↑                      ↑
```

the string they capture is "ab(cd)ef", the contents of the top level parentheses. If there are more than 15 capturing parentheses in a pattern, PCRE has to obtain extra memory to store data during a recursion, which it does by using pcre_malloc, freeing it via pcre_free afterward. If no memory can be obtained, the match fails with the PCRE_ERROR_NOMEMORY error.

Do not confuse the `(?R)` item with the condition `(R)`, which tests for recursion. Consider this pattern, which matches text in angle brackets, allowing for arbitrary nesting. Only digits are allowed in nested brackets (that is, when recursing), whereas any characters are permitted at the outer level.

```
< (?: (?(R) \d++  | [^<>]*+) | (?R)) * >
```

In this pattern, `(?(R)` is the start of a conditional subpattern, with two different alternatives for the recursive and nonrecursive cases. The `(?R)` item is the actual recursive call.

Subpatterns as Subroutines

If the syntax for a recursive subpattern reference (either by number or by name) is used outside the parentheses to which it refers, it operates like a subroutine in a programming language. An earlier example pointed out that the pattern

```
(sens|respons)e and \1ibility
```

matches "sense and sensibility" and "response and responsibility", but not "sense and responsibility". If instead the pattern

```
(sens|respons)e and (?1)ibility
```

is used, it does match "sense and responsibility" as well as the other two strings. Such references must, however, follow the subpattern to which they refer.

Regular Expressions References

The regular expression syntax supported by **Grep**, **GrepString**, **GrepList**, and **SplitString** is based on the *PCRE — Perl-Compatible Regular Expression Library* by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.

Visit <http://pcre.org/> for more information about the PCRE library, and <http://www.perldoc.com/> for more about Perl regular expressions. This description, Regular Expressions In Igor, is taken from the PCRE documentation.

A good introductory book on regular expressions is: Forta, Ben, *Regular Expressions in 10 Minutes*, Sams Publishing, 2004.

A good comprehensive book on regular expressions is: Friedl, Jeffrey E. F., *Mastering Regular Expressions*, 2nd ed., 492 pp., O'Reilly Media, 2002.

Working with Files

Here are the built-in operations that you can use to read from or write to files:

Operation	What It Does
Open	Opens an existing file for reading or writing. Can also create a new file. Can also append to an existing file. Returns a file reference number that you must pass to the other file operations. Use Open/D to present a dialog that allows the user to choose a file without actually opening the file.
fprintf	Writes formatted text to an open file.
wfprintf	Writes wave data as formatted text to an open file.
FSetPos	Sets the position at which the next file read or write will be done.
FStatus	Given a file reference number, returns miscellaneous information about the file.
FBinRead	Reads binary data from a file into an Igor string, variable or wave. This is used mostly to read nonstandard file formats.
FBinWrite	Writes binary data from an Igor string, variable or wave. This is used mostly to write nonstandard file formats.
FReadLine	Reads a line of text from a text file into an Igor string variable. This can be used to parse an arbitrary format text file.
Close	Closes a file opened by the Open operation.

Before working with a file, you must use the Open operation to obtain a file reference number that you use with all the remaining commands. The Open operation creates new files, appends data to an existing file, or reads data from an existing file. There is no facility to deal with the resource fork of a Macintosh file.

Sometimes you may write a procedure that uses the Open operation and the Close operation but, because of an error, the Close operation never gets to execute. You then correct the procedure and want to rerun it. The file will still be open because the Close operation never got a chance to run. In this case, execute:

```
Close/A
```

from the command line to close all open files.

Finding Files

The TextFile and IndexedFile functions help you to determine what files exist in a particular folder. IndexedFile is just a more general version of TextFile.

You can also use the Open operation with the /D flag to present an open dialog.

Other File– and Folder–Related Operations and Functions

Igor Pro also supports a number of operations and functions for file or folder manipulation:

CopyFile	CopyFolder
DeleteFile	DeleteFolder
GetFileFolderInfo	SetFileFolderInfo
MoveFile	MoveFolder
CreateAliasShortcut	
NewPath	PathInfo
ParseFilePath	

Warning: Use caution when writing code that deletes or moves files or folders. These actions are not undoable.

Because the DeleteFolder, CopyFolder and MoveFolder operations have the potential to do a lot of damage if used incorrectly, they require user permission before overwriting or deleting a folder. The user controls the permission process using the Miscellaneous Settings dialog (Misc menu).

Writing to a Text File

You can generate output text files from Igor procedures or from the command line in formats acceptable to other programs. To do this, you need to use the **Open** and **Close** operations and the **fprintf** operation (page V-183) and the **wfprintf** operation (page V-735).

The following commands illustrate how you could use these operations to create an output text file. Each operation is described in detail in following sections:

```
Variable f1                          //make refNum variable
Open f1 as "A New File"              //create and open file
fprintf f1, "wave1\twave2\twave3\r" //write column headers
wfprintf f1, "" wave1, wave2, wave3 //write wave data
Close f1                             //close file
```

Open and Close Operations

You use the **Open** operation (page V-460) to open a file. For our purposes, the syntax of the Open operation is:

```
Open [/R/A/P=pathName/M=messageStr] variableName [as "filename"]
```

variableName is the name of a numeric variable. The Open operation puts a file reference number in that variable. You will need the reference number to access the file after you've opened it.

A file specifications consists of a path (directions for finding a folder) and a file name. In the Open operation, you can specify the path in three ways:

Using a full path as the filename parameter:

```
Open refNum as "hd:Data:Run123.dat"
```

Or using a symbolic path name and a file name:

```
Open/P=DataPath refNum as "Run123.dat"
```

Or using a symbolic path name and a partial path including the file name:

```
Open/P=HDPath refNum as ":Data:Run123.dat"
```

A symbolic path is a short name that refers to a folder on disk. See **Symbolic Paths** on page II-34.

If you do not provide enough information to find the folder and file of interest, Igor puts up a dialog which lets you select the file to open. If you supply sufficient information, Igor will just open the file without putting up the dialog.

To open a file for reading, use the /R flag. To add new data to a file, use the /A flag. If you omit both of these flags, you will overwrite any data that is already in the file.

If you open a file for writing (you don't use /R) then, if there exists a file with the specified name, Igor opens the file and overwrites the existing data in the file. If there is no file with the specified name, Igor creates a new file.

Warning: If you're not careful you can inadvertently lose data using the Open operation by opening for writing without using the /A flag. To avoid this, use the /R (open for read) or /A (append) flags.

Wave Reference Functions

It is common to write a user-defined function that operates on all of the waves in a data folder, on the waves displayed in a graph or table, or on a wave identified by a cursor in a graph. For these purposes, you need to use wave reference functions.

Wave reference functions are built-in Igor functions that return a reference that can be used in a user-defined function. Here is an example that works on the top graph. Cursors are assumed to be placed on a region of a trace in the graph.

```
Function WaveAverageBetweenCursors()
   WAVE/Z w = CsrWaveRef(A)
   if (!WaveExists(w))        // Cursor is not on any wave.
      return NaN
   endif

   Variable xA = xcsr(A)
   Variable xB = xcsr(B)
   Variable avg = mean(w, xA, xB)

   return avg
End
```

CsrWaveRef returns a wave reference that identifies the wave a cursor is on.

An older function, CsrWave, returns the *name* of the wave the cursor is on. It would be tempting to use this to determine the wave the cursor is on, but it would be incorrect. The name of a wave by itself does not uniquely identify a wave because it does not specify the data folder in which the wave resides. For this reason, we usually need to use the wave reference function CsrWaveRef instead of CsrWave.

This example uses a wave reference function to operate on the waves displayed in a graph:

```
Function SmoothWavesInGraph()
   String list = TraceNameList("", ";", 1)
   String traceName
   Variable index = 0
   do
      traceName = StringFromList(index, list)
      if (strlen(traceName) == 0)
         break          // No more traces.
      endif
      WAVE w = TraceNameToWaveRef("", traceName)
      Smooth 5, w
      index += 1
   while(1)
End
```

Here are the wave reference functions. See Chapter V-1, **Igor Reference**, for details on each of them.

Function	Comment
CsrWaveRef	Returns a reference to the Y wave to which a cursor is attached.
CsrXWaveRef	Returns a reference to the X wave when a cursor is attached to an XY pair.
WaveRefIndexed	Returns a reference to a wave in a graph or table or to a wave in the current data folder.
XWaveRefFromTrace	Returns a reference to an X wave in a graph. Used with the output of TraceNameList.
ContourNameToWaveRef	Returns a reference to a wave displayed as a contour plot. Used with the output of ContourNameList.
ImageNameToWaveRef	Returns a reference to a wave displayed as an image. Used with the output of ImageNameList.

Function	Comment
TraceNameToWaveRef	Returns a reference to a wave displayed as a waveform or as the Y wave of an XY pair in a graph. Used with the output of TraceNameList.
TagWaveRef	Returns a reference to a wave to which a tag is attached in a graph. Used in creating a smart tag.
WaveRefsEqual	Returns the truth two wave references are the same.

It is possible to create a user-defined function that returns a wave reference via a structure parameter. For simple applications, it may be easier to create a string function that returns a full path to the wave. Here is an example:

```
Function/S CursorAWave()
   WAVE/Z w= CsrWaveRef(A)
   if (WaveExists(w)==0)
      return ""
   endif
   return GetWavesDataFolder(w,2)
End

Function DemoCursorAWave()
   WAVE/Z w= $CursorAWave()
   if (WaveExists(w)==0)
      Print "oops: no wave"
   else
      Print "Cursor A is on the wave", WaveName(w)
   endif
End
```

DemoCursorAWave uses the $ operator to convert the full path to the wave returned by CursorAWave into a wave reference stored in w.

Processing Lists of Waves

Igor users often want to use a string list of waves in places where Igor is looking for just the name of a single wave. For example, they would like to do this:

```
Display "wave0;wave1;wave2"
```

or, more generally:

```
Function DisplayListOfWaves(list)
   String list                // e.g., "wave0;wave1;wave2"

   Display $list
End
```

Unfortunately, Igor can't handle this. However, there are techniques for achieving the same result.

Graphing a List of Waves

This example illustrates the basic technique for processing a list of waves.

```
Function DisplayWaveList(list)
   String list             // A semicolon-separated list.

   String theWave
   Variable index=0

   do
      // Get the next wave name
      theWave = StringFromList(index, list)
      if (strlen(theWave) == 0)
```

```
         break                        // Ran out of waves
      endif
      if (index == 0)                 // Is this the first wave?
         Display $theWave
      else
         AppendToGraph $theWave
      endif
      index += 1
   while (1)          // Loop until break above
End
```

To make a graph of all of the waves in the current data folder, you would execute

```
DisplayWaveList(WaveList("*", ";", ""))
```

Operating on the Traces in a Graph

In a previous section, we showed an example that operates on the waves displayed in a graph. It used a wave reference function, TraceNameToWaveRef. If you want to write a function that operates on *traces* in a graph, you would *not* use wave reference functions. That's because Igor operations that operate on *traces* expect *trace names*, not wave references. For example:

```
Function GrayOutTracesInGraph()
   String list = TraceNameList("", ";", 1)
   String traceName
   Variable index = 0
   do
      traceName = StringFromList(index, list)
      if (strlen(traceName) == 0)
         break                        // No more traces.
      endif

      // WRONG: ModifyGraph expects a trace name and w is not a trace name
      WAVE w = TraceNameToWaveRef("", traceName)
      ModifyGraph rgb(w)=(50000,50000,50000)

      // RIGHT
      ModifyGraph rgb($traceName)=(50000,50000,50000)

      index += 1
   while(1)
End
```

Using a Fixed-Length List

In the previous examples, the number of waves in the list was unimportant and all of the waves in the list served the same purpose. In this example, the list has a fixed number of waves and each wave has a different purpose.

```
Function DoLineFit(list)
   String list          // List of waves names: source, dest, weight
   String source, dest, weight

   // Pick out the expected wave names
   source = StringFromList(0, list)
   dest = StringFromList(1, list)
   weight = StringFromList(2, list)

   CurveFit line $source /D=$dest /W=$weight
End
```

You would invoke this function as follows:

```
DoLineFit("wave0;wave1;wave2")
```

Operating on Qualified Waves

This example illustrates how to operate on waves that match a certain criterion. It is broken into two functions - one that creates the list of qualified waves and a second that operates on them. This organization gives us a general purpose routine (ListOfMatrices) that we would not have if we wrote the whole thing as one function.

```
Function/S ListOfMatrices()
   String list = ""
   Variable index=0
   do
      WAVE/Z w=WaveRefIndexed("",index,4)    // Get next wave.
      if (WaveExists(w) == 0)
         break                               // No more waves.
      endif
      if (DimSize(w,1)>0 && DimSize(w,2)==0)
         // Found matrix. Add to list with separator.
         list += NameOfWave(w) + ";"
      endif
      index += 1
   while(1)             // Loop till break above.
   return list
End

Function ChooseAndDisplayMatrix()
   String theList = ListOfMatrices()

   String theMatrix
   Prompt theMatrix, "Matrix to display:", popup theList
   DoPrompt "Display Matrix", theMatrix
   if (V_Flag != 0)
      return -1
   endif

   WAVE m = $theMatrix
   NewImage m
End
```

The ExecuteCmdOnList Function

The ExecuteCmdOnList function is implemented by a WaveMetrics procedure file and executes any command for each wave in the list. For example, the following commands do a WaveStats operation on each wave.

```
Make wave0=gnoise(1), wave1=gnoise(10), wave2=gnoise(100)
ExecuteCmdOnList("WaveStats %s", "wave0;wave1;wave2;")
```

The ExecuteCmdOnList function is supplied in the Execute Cmd On List procedure file. See **The Include Statement** on page IV-145 for instructions on including a procedure file.

This technique is on the kludgy side. If you can achieve your goal in a more straightforward fashion without heroic efforts, you should use regular programming techniques.

The Execute Operation

Execute is a built-in operation that executes a string expression as if you had typed it into the command line. The main purpose of Execute is to get around the restrictions on calling macros and external operations from user functions.

We try to avoid using Execute because it makes code obscure and difficult to debug. If you can write a procedure without Execute, do it. However, there are some cases where using Execute can save pages of code or achieve something that would otherwise be impossible.

It is a good idea to compose the command to be executed in a local string variable and then pass that string to the Execute operation. Use this to print the string to the history for debugging. For example:

```
String cmd
sprintf cmd, "GBLoadWave/P=%s/S=%d \"%s\"", pathName, skipCount, fileName
Print cmd          // For debugging
Execute cmd
```

It is not necessary to use Execute to call the GBLoadWave external operation because it can be called directly from a user function. Prior to Igor Pro 5, this was not possible.

When you use Execute, you must be especially careful in the handling of wave names. See **Programming with Liberal Names** on page IV-147 for details.

When Execute runs, it is as if you typed a command in the command line. Local variables in macros and functions are not accessible. The example in **Calling an External Operation From a User-Defined Function** on page IV-177 shows how to use the sprintf operation to solve this problem.

Using a Macro From a User-Defined Function

A macro can not be called directly from a user function. To do so, we must use Execute. This is a trivial example for which we would normally not resort to Execute but which clearly illustrates the technique.

```
Function Example()
   Make wave0=enoise(1)
   Variable/G V_avg              // Create a global
   Execute "MyMacro(\"wave0\")"  // Invokes MyMacro("wave0")
   return V_avg
End

Macro MyMacro(wv)
   String wv
   WaveStats $wv     // Sets global V_avg and 9 other local vars
End
```

Execute does not supply good error messages. If the macro generates an error, you may get a cryptic message. Therefore, debug the macro *before* you call it with the Execute operation.

Calling an External Operation From a User-Defined Function

Prior to Igor Pro 5, external operations could not be called directly from user-defined functions and had to be called via Execute. Now it is possible to write an external operation so that it can be called directly. However, old XOPs that have not been updated still need to be called through Execute. This example shows how to do it.

If you attempt to directly use an external operation which does not support it, you will see an error dialog telling you to use Execute for that operation.

The external operation in this case is VDTWrite which sends text to the serial port. It is implemented by the VDT XOP.

```
Function SetupVoltmeter(range)
   Variable range    // .1, .2, .5, 1, 2, 5 or 10 volts

   String voltmeterCmd
   sprintf voltmeterCmd, "DVM volts=%g", range
   String vdtCmd
   sprintf vdtCmd "VDTWrite \"%s\"\r\n", voltmeterCmd
   Execute vdtCmd
End
```

In this case, we are sending the command to a voltmeter that expects something like:

```
DVM volts=.2<CR><LF>
```

to set the voltmeter to the 0.2 volt range.

The parameter that we send to the Execute operation is:

```
VDTWrite "DVM volts=.2\r\n"
```

The backslashes used in the second sprintf call insert two quotation marks, a carriage return, and a linefeed in the command about to be executed.

A newer VDT2 XOP exists which includes external operations that *can* be directly called from user-functions. Thus, new programming should use the VDT2 XOP and will not need to use Execute.

Other Uses of Execute

Execute can also accept as an argument a string variable containing commands that are algorithmically constructed. Here is a simple example:

```
Function Fit(w, fitType)
   WAVE w               // Source wave
   String fitType       // One of the built-in Igor fit types

   String name = NameOfWave(w)
   name = PossiblyQuoteName(name)   // Liberal names need quotes

   String cmd
   sprintf cmd, "CurveFit %s %s", fitType, name
   Execute cmd
End
```

Use this function to do any of the built-in fits on the specified wave. Without using the Execute operation, we would have to write it as follows:

```
Function Fit(w, fitType)
   WAVE w                  // Source wave
   String fitType          // One of the built-in Igor fit types

   strswitch(fitType)
      case "line":
         CurveFit line w
         break

      case "exp":
         CurveFit exp w
         break

      <and so on for each fit type>
   endswitch
End
```

Note the use of sprintf to prepare the string containing the command to be executed. The following would not work because when Execute runs, local variables and parameters are not accessible:

```
Execute "CurveFit fitType name"
```

Deferred Execution Using the Operation Queue

It is sometimes necessary to execute a command after the current function has finished. This is done using the Execute/P operation. For details, see **Operation Queue** on page IV-250.

Procedures and Preferences

You can set many preferences. Most of the preferences control the style of new objects, including new graphs, traces and axes added to graphs, new tables, columns added to tables and so on.

Preferences are usually used only for manual “point-and-click” operation. We usually don’t want preferences to affect the behavior of procedures. The reason for this is that we want a procedure to do the same

thing no matter who runs it. Also, we want it to do the same thing tomorrow as it does today. If we allowed preferences to take effect during procedure execution, a change in preferences could change the effect of a procedure, making it unpredictable.

By default, preferences do not take effect during procedure execution. If you want to override the default behavior, you can use the Preferences operation. From within a procedure, you can execute "`Preferences 1`" to turn preferences on. This affects the procedure and any subroutines that it calls. It stays in effect until you execute "`Preferences 0`".

When a *macro* ends, the state of preferences reverts to what it was when that macro started. If you change the preference setting within a *function*, the preferences state does *not* revert when that function ends. You must turn preferences on, save the old preferences state, execute Igor operations, and then restore the preferences state. For example:

```
Function AppendWithCapturedAxis()
   Variable oldPrefState
   Preferences 1;                    // Turn preferences on and
   oldPrefState = V_Flag             // save the old state.

   Make wave0=x
   Display/L=myCapturedAxis wave0    // myCapturedAxis is pref axis.

   Preferences oldPrefState          // Restore old prefs state.
End
```

Experiment Initialization Procedures

When Igor loads an experiment, it checks to see if there are any commands in the procedure window before the first macro, function or menu declaration. If there are such commands Igor executes them. This provides a way for you to initialize things. These initialization commands can invoke procedures that are declared later in the procedure window.

Also see **BeforeFileOpenHook** on page IV-259 and **IgorStartOrNewHook** on page IV-263 for other initialization methods.

Procedure Subtypes

A procedure subtype identifies the purpose for which a particular procedure is intended and the appropriate menu from which it can be chosen. For example, the Graph subtype puts a procedure in the Graph Macros submenu of the Windows menu.

```
Window Graph0() : Graph
   PauseUpdate; Silent 1      // building window...
   Display/W=(5,42,400,250) wave0,wave1,wave2
   <more commands>
End
```

When Igor automatically creates a procedure, for example when you close and save a graph, it uses the appropriate subtype. When you create a curve fitting function using the Curve Fitting dialog, the dialog automatically uses the FitFunc subtype. You usually don't need to use subtypes for procedures that you write.

This table shows the available subtypes and how they are used.

Subtype	Effect	Available for
Graph	Displayed in Graph Macros submenu.	Macros
GraphStyle	Displayed in Graph Macros submenu and in Style pop-up menu in New Graph dialog.	Macros
GraphMarquee	Displayed in graph marquee. This keyword is no longer recommended. See **Marquee Menu as Input Device** on page IV-140 for details.	Macros and functions
Table	Displayed in Table Macros submenu.	Macros
TableStyle	Displayed in Table Macros submenu and in Style pop-up menu in New Table dialog.	Macros
Layout	Displayed in Layout Macros submenu.	Macros
LayoutStyle	Displayed in Layout Macros submenu and in Style pop-up menu in New Layout dialog.	Macros
LayoutMarquee	Displayed in layout marquee. This keyword is no longer recommended. See **Marquee Menu as Input Device** on page IV-140 for details.	Macros and functions
Panel	Displayed in Panel Macros submenu.	Macros
FitFunc	Displayed in Function pop-up menu in Curve Fitting dialog.	Functions
ButtonControl	Displayed in Procedure pop-up menu in Button Control dialog.	Macros and functions
CheckBoxControl	Displayed in Procedure pop-up menu in Checkbox Control dialog.	Macros and functions
PopupMenuControl	Displayed in Procedure pop-up menu in PopupMenu Control dialog.	Macros and functions
SetVariableControl	Displayed in Procedure pop-up menu in SetVariable Control dialog.	Macros and functions

Memory Considerations

The maximum amount of memory available to Igor Pro (or any application) is 4 GB on Macintosh and 2, 3, or 4 GB on Windows regardless of the amount of installed RAM. Virtual memory on disk is always used, being constrained only by available disk space and access speed. See **Memory Management** on page III-425 for more information.

These memory limits are adequate for most applications although you may be surprised by out of memory errors with much less apparent memory usage. Oftentimes such errors are caused by fragmentation of RAM and the inability of either operating system to combine adjacent blocks of deallocated memory to create a contiguous memory block.

Most often such memory fragmentation occurs when you create and destroy many large waves during function execution. The best way to avoid these memory problems is to create these large waves once at the start of your function and then reuse them rather than killing and remaking them. The reason is that if you use Redimension to shrink a large wave, then a following Redimension that increases the wave size should succeed as it will be expanding back into the same memory block. You can also use Make/O can in place of Redimension.

Wave Reference Counting

The method Igor Pro uses to deallocate memory when waves are killed was improved in Igor Pro 6. The new method uses reference counting to determine when a wave is no longer referenced anywhere and memory can be safely deallocated, which should reduce the likelihood of out of memory errors, especially on Macintosh.

Because memory is not deallocated until all references to a given wave are gone, memory may not be freed when you think. Consider the function:

```
Function myfunc()
   Make/N=10E6 bigwave
   // do stuff
   FunctionThatKillsBigwave()
   // do more stuff
End
```

The memory allocated for bigwave is not deallocated until the function returns because an automatic WAVE reference variable of the same name still references the wave. To free memory for the second part, use the **WAVEClear** operation (page V-722):

```
Function myfunc()
   Make/N=10E6 bigwave
   // do stuff
   FunctionThatKillsBigwave()
   WAVEClear bigwave
   // do more stuff
End
```

The WAVEClear command takes a list of WAVE reference variables and stores NULL into them. It is the same as:

```
WAVE/Z wavref= $""
```

If you see the message "BUG: DecrementWaveRefCount" printed in the history area, please notify support@wavemetrics.com. If possible, please provide the steps necessary to reproduce the message.

If you suspect the new method is causing problems (a crash could occur if a reference was missed and a killed wave was accessed,) you can revert to the old method by executing

```
SetIgorOption doWAVERefCount= 0
```

You should do this in a blank experiment because it affects function compiling. You can revert to the new method by restarting Igor Pro or by executing

```
SetIgorOption doWAVERefCount= 2.
```

Creating Igor Extensions

Igor includes a feature that allows a C or C++ programmer to extend its capabilities. Using Apple's Xcode or Microsoft Visual C++, a programmer can add command line operations and functions to Igor. These are called external operations and external functions. Experienced programmers can also add menu items, dialogs and windows.

A file containing external operations or external functions is called an "XOP file" or "XOP" (pronounced "ex-op") for short.

Here are some things for which you might want to write an XOP:

- To do number-crunching on waves.
- To import data from a file format that Igor does not support.
- To acquire data directly into Igor waves.
- To communicate with a remote computer, instrument or database.

The main reasons for writing something as an XOP instead of writing it as an Igor procedure are:

- It needs to be blazing fast.
- You already have a lot of C code that you want to reuse.
- You need to call drivers for data acquisition.
- It requires programming techniques that Igor doesn't support.

- You want to add your own dialogs or windows.

Writing an XOP that does number-crunching is considerably easier than writing a stand-alone program. You don't need to know anything about the Macintosh Toolbox or the Windows API. Writing an XOP that adds dialogs or windows to Igor requires more knowledge but is still easier than writing a stand-alone program.

If you are a C or C++ programmer and would like to extend Igor with your own XOP, you will need to purchase the Igor External Operations Toolkit from WaveMetrics. This toolkit contains documentation on writing XOPs as well as the source code for many of the WaveMetrics sample XOPs. It supplies a large library of routines that enable communication between Igor and the external code. You will also need the a recent version of Xcode, or Microsoft Visual C++.

Chapter
IV-8

Debugging

Debugging Procedures

There are two techniques for debugging procedures in Igor:

- Using print statements
- Using the symbolic debugger

For most situations, the symbolic debugger is the most effective tool. In some cases, a strategically placed print statement is sufficient.

Debugging With Print Statements

This technique involves putting print statements at a certain point in a procedure to display debugging messages in Igor's history area. In this example, we use Printf to display the value of parameters to a function and then Print to display the function result.

```
Function Test(w, num, str)
   Wave w
   Variable num
   String str

   Printf "Wave=%s, num=%g, str=%s\r", NameOfWave(w), num, str

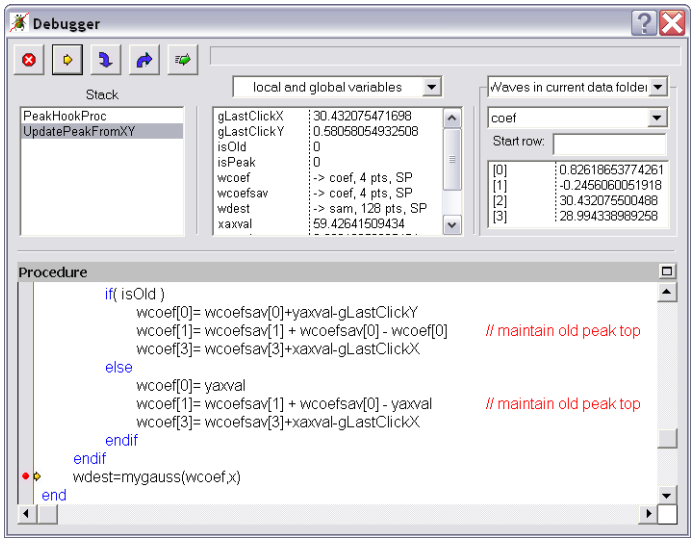
   <body of function>

   Print result
   return result
End
```

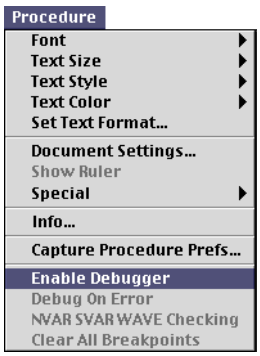
See **Creating Formatted Text** on page IV-230 for details on the Printf operation.

The Debugger

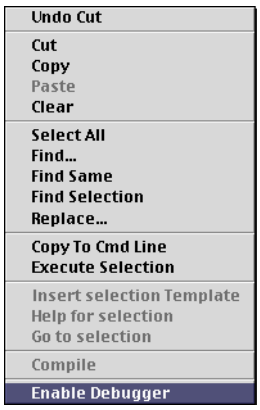
When a procedure doesn't produce the results you want, you can use Igor's built-in debugger to observe the execution of user-defined macros and functions while single-stepping through the lines of code.



The debugger is normally disabled. Enable it using either the Procedure menu or by Control-clicking (*Macintosh*) or right-clicking (*Windows*) in any procedure window to get the pop-up menu:



Procedure Menu



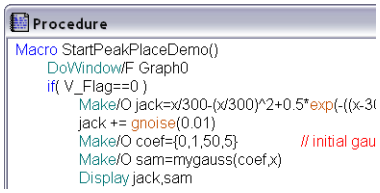
Contextual menu

The debugger window will automatically appear when one of the following events occurs:

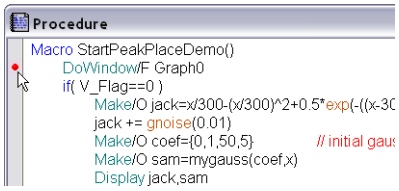
1. A breakpoint that you previously set is encountered.
2. An error occurs, and you have enabled debugging on that kind of error.
3. An error dialog is presented, and you click the Debug button.

Setting Breakpoints

When you want to observe a particular routine in action, set a breakpoint on the line where you want the debugger to appear. To do this, open the procedure window which contains the routine, and click in the left "breakpoint margin". The breakpoint margin appears only if the debugger has been enabled:



Debugger Disabled



Debugger Enabled

When a line of code marked with the red dot (denoting a set breakpoint) is about to execute, the debugger window will appear.

Click the red dot again to clear the breakpoint. Control-click (*Macintosh*) or right-click (*Windows*) and use the pop-up menu to clear all breakpoints or disable a breakpoint on the currently selected line of the procedure window.

Debugging on Error

You can automatically open the debugger window when an error occurs. There are two categories of errors to choose from:

Debug On Error	Any runtime error except failed NVAR, SVAR, or WAVE references.
NVAR SVAR WAVE Checking	Failed NVAR, SVAR, or WAVE references.

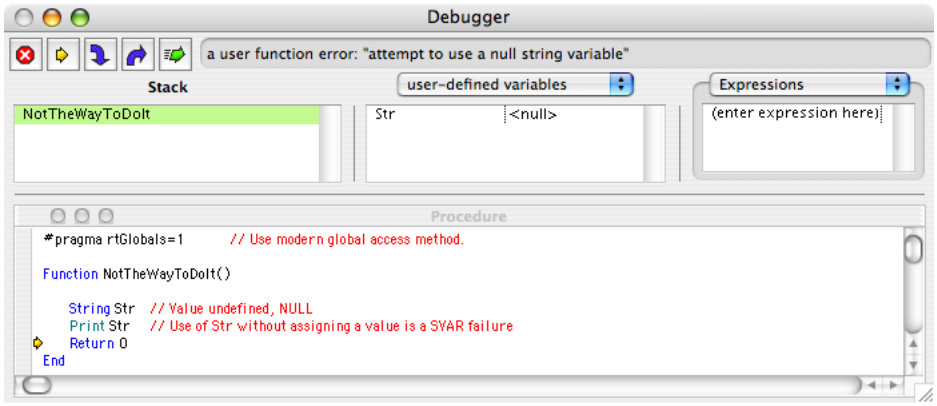
You can use the /Z flag to hide failures from SVAR, NVAR and WAVE checking. This is appropriate where the reference is subsequently checked with WaveExists, NVAR_Exists, or SVAR_Exists:

```
WAVE/Z wv=<pathToPossiblyMissingWave>

if( WaveExists(wv) )
   <do something with wv>
endif
```

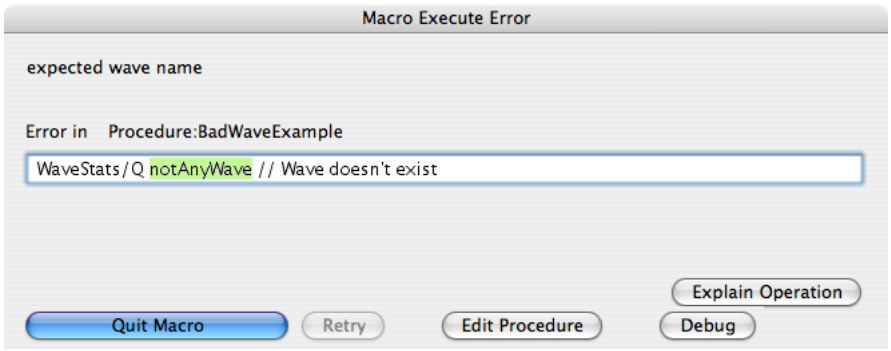
See **Runtime Lookup of Globals** on page IV-50 for details.

Use the Procedure or pop-up menus to choose either or both error categories. If the selected error occurs, the debugger will open and an error message will appear in the debugger window's status area. The error message was generated by the command *above* the yellow arrow:



Macro Execute Error: The Debug Button

When the debugger is enabled and an error occurs in a Macro, an error dialog is presented that will (usually) have a Debug button in it. Click the button to open the debugger window.



Errors in macros (or procs) are reported immediately after they occur.

When an error is reported by a function, a different dialog appears long after the error was actually committed. The Debug On Error option catches errors in functions immediately after they are committed.

Stepping Through Your Code

Begin by enabling the debugger and setting a breakpoint on the line of code you are interested in, or begin when the debugger automatically opens because of an error. Use the buttons at the top of the debugger window to step through your code:

The Stop button ceases execution of the running function or macro before it completes. This is equivalent to clicking Igor's Abort button (*Windows*) or pressing Command-period (*Macintosh*) while the procedure is running.

Keyboard shortcuts: (none)

Note: Pressing Command-period on a Macintosh while the debugger window is showing is equivalent to clicking the *Go* button, not the Stop button.

The Step Over button executes the next line. If the line contains a call to one or more subroutines, execution continues until the subroutines return or until an error or breakpoint is encountered. Upon return, execution halts until you click a different button.

Keyboard shortcuts: Enter, keypad Enter, or Return

The Step Into button executes the next line. If that line contains a call to one or more subroutines, execution halts when the first subroutine is entered. The Stack list of currently executing routines shows the most recently entered routine as the last item in the list.

Keyboard shortcuts: +, =, or keyPad +

The Step Out button executes until the current subroutine is exited, or an error or breakpoint is encountered.

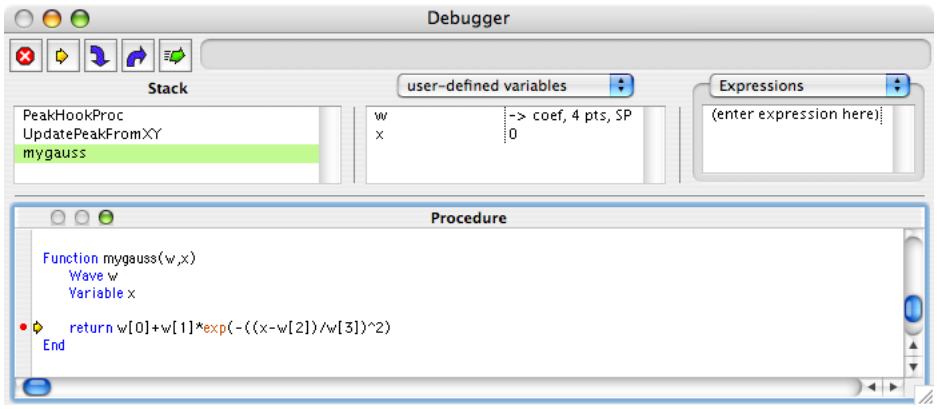
Keyboard shortcuts: -, _ (underscore) or keypad -

The Go button resumes program execution. The debugger window remains open until execution completes or an error or breakpoint is encountered.

Keyboard shortcuts: Esc

The Stack and Variables Lists

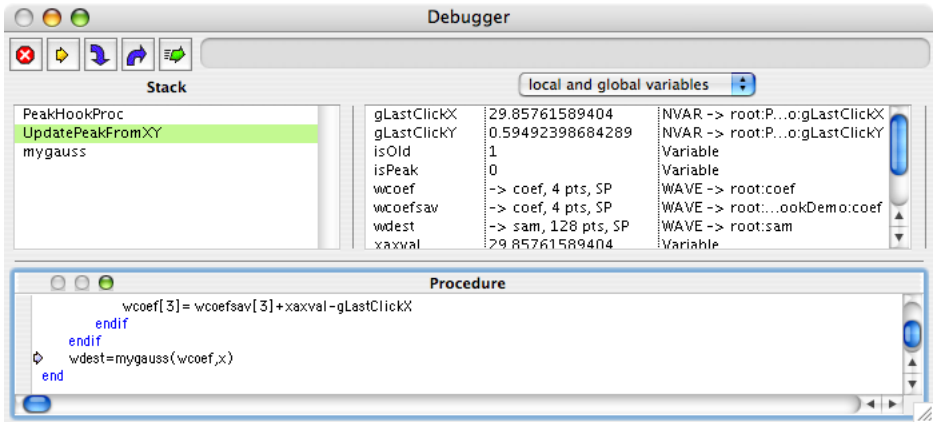
The Stack List shows the routine that is currently executing and the chain of routines that called it. The top item in the list is the routine that began execution and the bottom item is the routine which is currently executing.



In this example, the routine that started execution is PeakHookProc, which most recently called UpdatePeakFromXY, which then called the currently executing mygauss user function.

The Variables List (to the right of the Stack List) shows that the function parameters w and x have the values coef (a wave) and 0 (a number). The pop-up menu controls which variables are displayed in the list; the example shows only user-defined local variables.

You can examine the variables associated with any routine in the Stack List by simply selecting the routine:



Here we've selected UpdatePeakFromXY, the routine that called mygauss (see the light blue arrow). Notice that the Variables List is showing the variables that are local to UpdatePeakFromXY.

For illustration purposes, the Variables List has been resized by dragging the dividing line, and the pop-up menu has been set to show local and global variables and type information.

The Variables List Columns

The Variables List shows either two or three columns, depending on whether the "show variable types" item in the Variable pop-up menu is checked.

The first column is the name of the local variable. Note that the name of an NVAR, SVAR, or WAVE reference is a local name referring to a global object.

The second column is the value of the local variable. Double-click the second column to edit strings or variables.

In the case of a wave, the size and precision of the wave are shown here. The "->" characters mean "refers to". In our example wcoef is a local name that refers to a (global) wave named coef, which is one-dimensional, has 4 points, and is single precision.

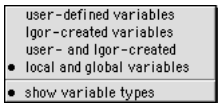
To determine the value of a particular wave element, use the **Wave, Structures, and Expressions Pane** on page IV-191.

The third (optional) column shows what the type of the variable is, whether Variable, String, NVAR, SVAR, or WAVE. For global references, the full path (including the data folder) to the global is shown.

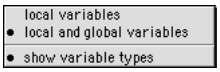
Note: The currentDF item is separated by a dashed line because currentDF is not really a global variable; it is a convenient name to identify the current data folder. See Chapter II-8, **Data Folders**, for more information about data folders.

Variables Pop-Up Menu

The Variables pop-up menu controls which information is displayed in the Variables List. The menu items differ when the routine chosen from the Stack List is a function or a macro/proc:



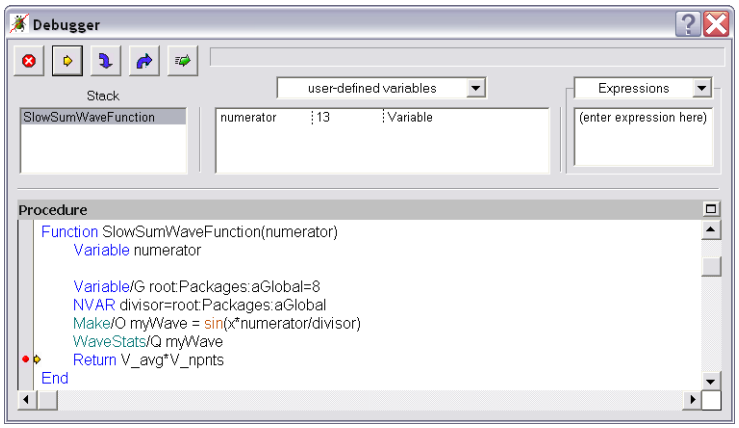
Pop-up Menu for Functions



Pop-up Menu for Macros, Procs, and Windows

Function Variables

The SlowSumWaveFunction example below illustrates how different kinds of variables in functions are classified:

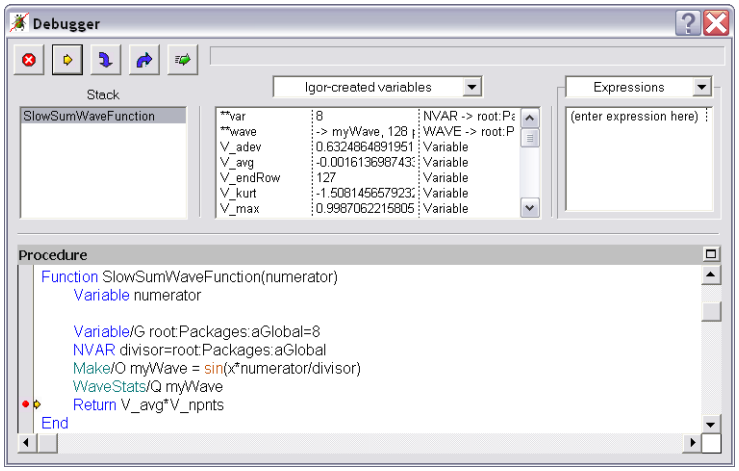


User-defined variables in functions include all items passed as parameters (numerator in this example) and any local strings and variables.

Local variables exist while a procedure is running, and cease to exist when the procedure returns; they never exist in a data folder like globals do.

NVAR, SVAR, WAVE, Variable/G and String/G references point to global variables, and therefore, aren't listed as user-defined (local) variables.

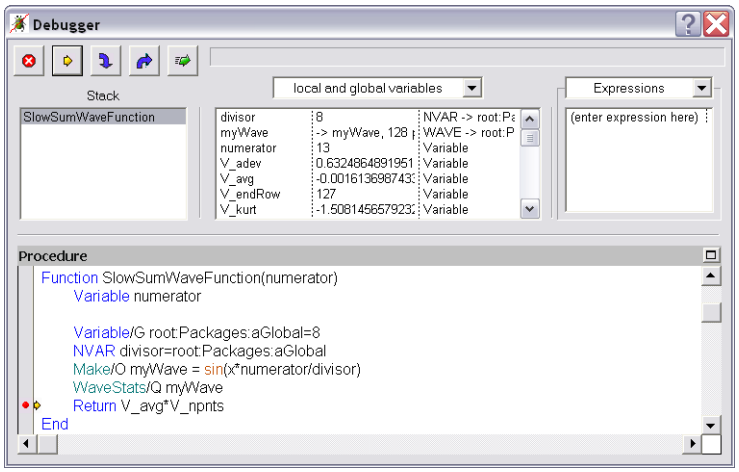
Use "Igor-created variables" to show local variables that Igor creates for functions when they call an operation or function that returns results in specially-named variables. The **WaveStats** operation (see page V-729), for example, defines V_adev, V_avg, and other variables to contain the statistics results:



Note: Some global references are created automatically for commands such as the Make operation; they have names that start with "**". These are shown only when Igor-created variables is selected.

The "user- and Igor-created" menu item shows both kinds of local variables.

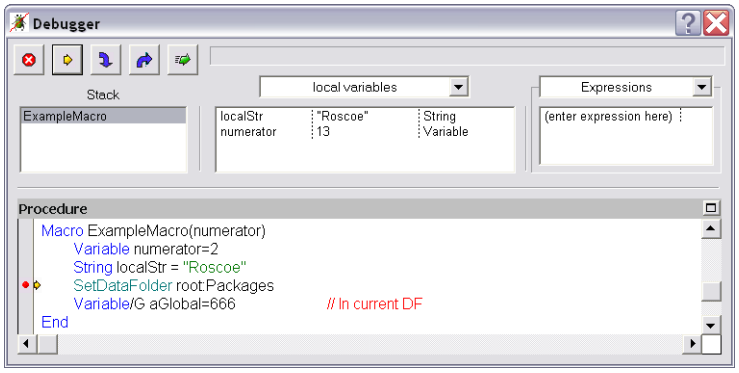
The "local and global variables" item shows user-created local variables, most Igor-created local variables, and references to global variables and waves through NVAR, SVAR, and WAVE references:



Choosing "local and global variables" also displays the current data folder at the end of the list as the mythical currentDF variable (see **The Variables List Columns** on page IV-188).

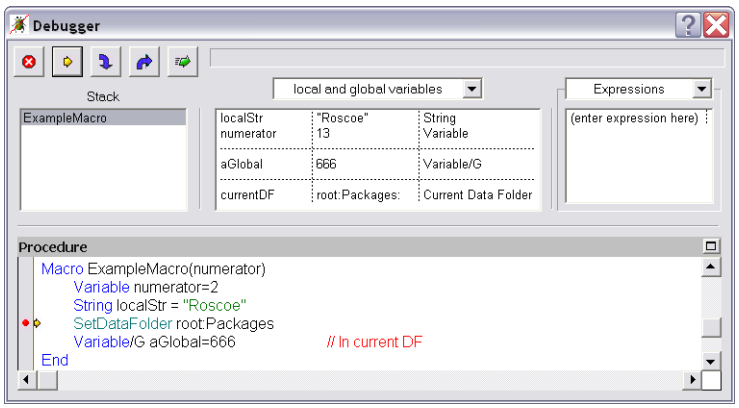
Macro Variables

The ExampleMacro below illustrates how variables in Macros, Procs or Window procedures are classified as locals or globals:



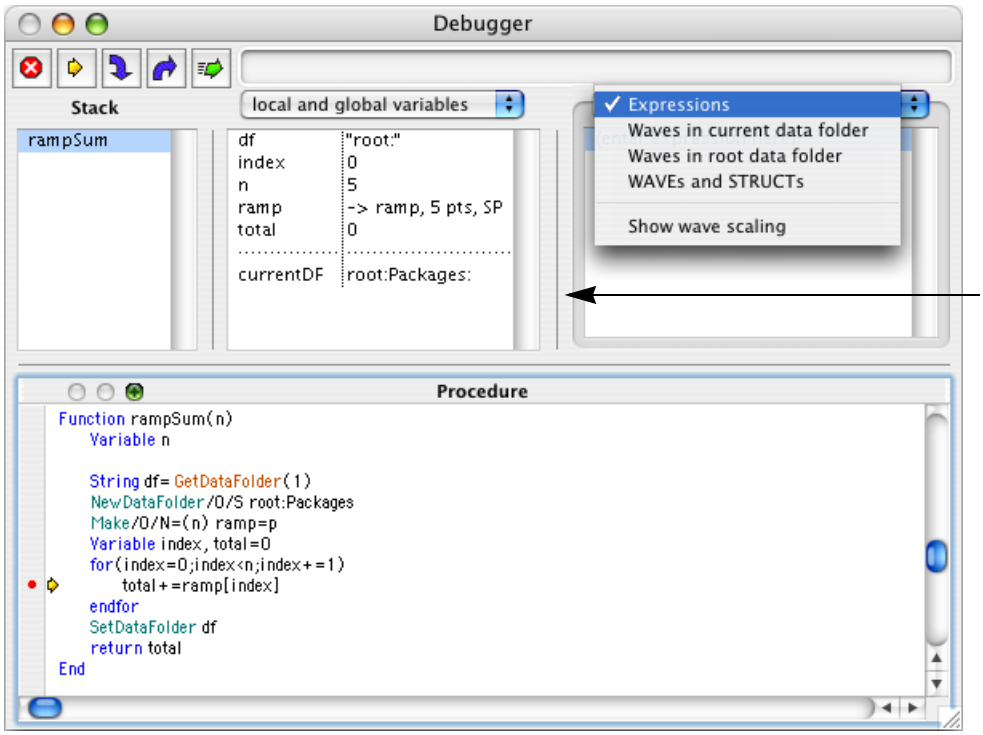
Local variables in macros include all items passed as parameters (numerator in this example) and local variables and local strings (localStr), and Igor-created local variables created by operations such as WaveStats.

Global variables in macros include all items in the current data folder, whether they are used in the macro or not. If the data folder changes because of a SetDataFolder operation, the list of global variables also changes. Note that there are no NVAR, SVAR, WAVE, or STRUCT references in a macro.



Wave, Structures, and Expressions Pane

The waves, structures, and expressions pane is on the right side of the variables list:



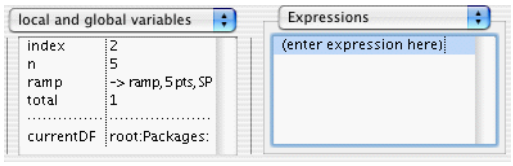
This pane is hidden when there isn't enough room or when the divider between the pane and the variables list is dragged all the way to the right. Drag the divider to the left to show the pane. You may need to widen the window to make room.

The pop-up menu controls what is shown in the pane:

Pop-up Menu Selection	Pane Contents
Expressions	Numeric or string expressions which are evaluated in the context of the selected function or macro.
Waves in current data folder	A list of waves in the current data folder and the contents of one selected wave.
Waves in root data folder	The same, but for the root: data folder.
WAVEs and STRUCTs	A list of WAVE and STRUCT references in the selected function. Disabled when a macro or proc is selected in the Stack list.
Show wave scaling	When unchecked, wave indexes are shown using rows, columns, layers, and chunks. The values are enclosed in square brackets. When checked, wave indexes are shown using the scaled values (see **Waveform Model of Data** on page II-77) and the value are enclosed in parentheses

Expressions

Replace the "(enter expression here)" prompt:



by clicking it, typing a numeric or string expression, and pressing Return.

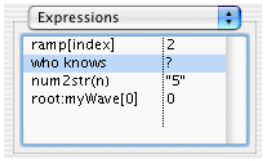
Adding an expression adds a blank row at the end of the list that can be double-clicked to enter another expression. You can edit any of the expressions by double-clicking and typing.

The expression can be removed by selecting it and pressing Delete or Backspace.

The result of the expression will be recomputed when stepping through procedures. The expressions are evaluated in the context of the currently selected procedure.

Global expressions are evaluated in the context of the current data folder, though you can specify the data folder explicitly as in the example below.

If an expression is invalid the result is shown as "?":

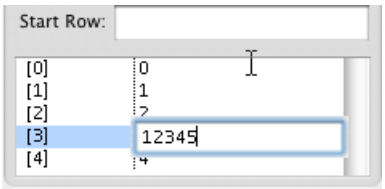


The expressions are discarded when a new Igor experiment is opened or when Igor quits.

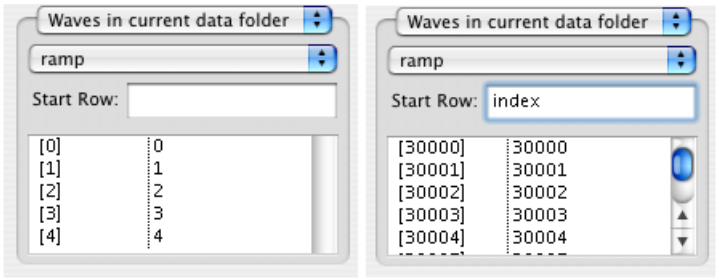
Waves in Current or Root Data Folder

The debugger shows the waves in the specified data folder. You can select one of the waves to inspect a one-dimensional portion.

You can edit the value of a wave element by double-clicking the value column and editing the value there. Press return to enter the value.

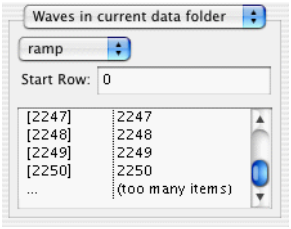


For a one-dimensional wave, you can specify the first row of the wave to display in the "Start Row:" control, or leave it blank to display starting with row 0. To look beyond the start of very long waves, you can enter a number or numeric expression into "Start Row:"



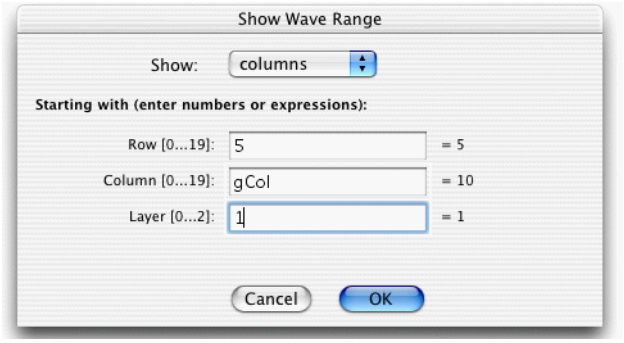
The wave value list will display only a limited number of rows, 1024 by default, in order to keep the debugger from being sluggish. When the list cannot display all of the rows, the last row in the list will say "(too many items)". You can change the maximum number of rows displayed here with the SetIgorOption command:

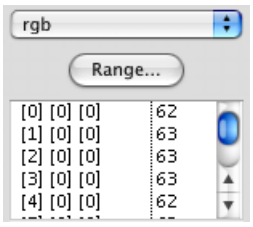
```
SetIgorOption DebuggerWaveRows=numRows
```



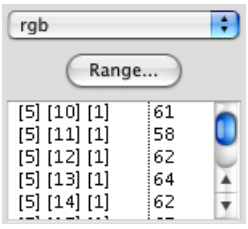
Use the Start Row to bring the row you wish to inspect within view.

Multidimensional waves can also be viewed, but only a one-dimensional subset. To view a particular range of values use the "Range..." button (which appears only when a multidimensional wave is chosen in the pop-up menu) and the resulting Show Wave Range dialog:



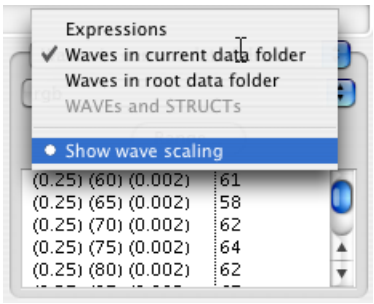


Default: rows 0 … n of column 0, layer 0



rows 5 … of column 10, layer 1

Choose "Show wave scaling" to display wave indexes using the scaled values (see **Waveform Model of Data** on page II-77). Scaled values are displayed in parentheses:



WAVEs and STRUCTs

WAVE and STRUCT references are allowed only in functions, so this pop-up menu choice is disabled when the routine selected in the Stack list is a macro or proc.

A WAVE reference points to a global wave, which can be in any data folder.

A STRUCT reference points to a structure which exists on the runtime stack and does not exist as a global object in any data folder.

Each is composed of individual elements, and these can be inspected in the list in this pane.

Here's the code of an example contrived to demonstrate inspecting a structure's elements using the WAVEs and STRUCTs pane:

```
Structure stuff
   String traces
   Variable nTraces
   STRUCT traceStuff trace[2]
EndStructure

Structure traceStuff
   Variable ndx
   String trace
   WAVE w
EndStructure

Function top(graph)
   String graph

   STRUCT stuff s

   s.traces=TraceNameList(graph, ";", 1 )
   s.nTraces= ItemsInList(s.traces)

   STRUCT traceStuff ts

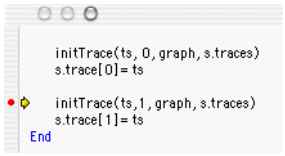
   initTrace(ts, 0, graph, s.traces)
   s.trace[0]= ts

   initTrace(ts,1, graph, s.traces)       // breakpoint set here
   s.trace[1]= ts
End

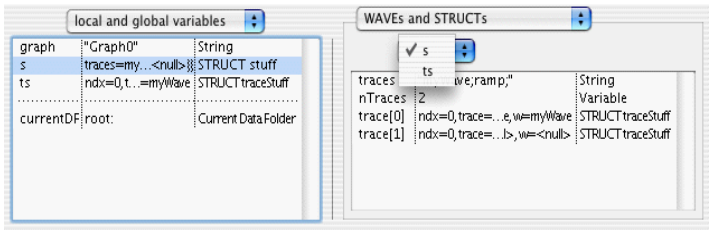
Function initTrace(ts, index, graph, traces)
   STRUCT traceStuff &ts
   Variable index
   String graph, traces
```

```
    ts.ndx= index
    ts.trace= StringFromList(index,traces)
    WAVE ts.w=TraceNameToWaveRef(graph, ts.trace)
End
```

Running top("Graph0") with the breakpoint at the second initTrace call



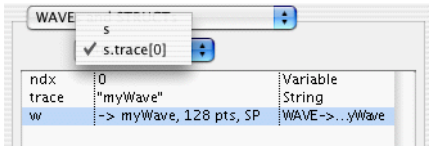
results in the Variables list shown below. You can see in the Variables list that "s" is the name of structure of type "stuff":



Double-clicking the structure s row in the Variables list (or selecting s from the pop-up menu of WAVEs and STRUCTs) displays the content of the structure.

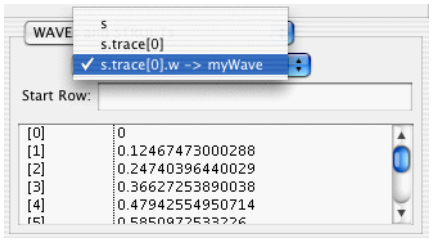
You can see that the listing of the contents of a structure on a single line is of limited use!

To see the contents of STRUCT traceStuff trace[0], double-click the trace[0] row in the WAVEs and STRUCTs list:



You can edit the value of ndx and trace by double-clicking the second column.

To see the contents of s.trace[0].w, double-click w's row:



You can edit the values of myWave by double-clicking the second column.

Use the pop-up menu to view previous levels of the s structure. When you choose the top-level ("s"), the menu will again be filled with all the WAVEs and STRUCTs in the currently selected function.

The Procedure Pane

The procedure pane contains a copy of the procedure window of the routine selected in the Stack List. You can set and clear breakpoints in this pane just as you do in a procedure window, using the breakpoint margin and the Control-click (*Macintosh*) or right-click (*Windows*) menu.

A very useful feature of the debugger is the automatic text expression evaluator that shows the value of a variable or expression under the cursor. On the Macintosh, the value is displayed in the top-right corner of the debugger. On Windows, a tooltip is displayed near the cursor.

This is often faster than scrolling through the Variables List or entering an expression in the Expressions List to determine the value of a variable, wave, or structure member reference.

The value of a variable can be displayed whether or not the variable name is selected. To evaluate an expression such as "wave[ii]+3", the expression must be selected and the cursor must be over the selection.

The debugger won't evaluate expressions that include calls to user-defined functions; this prevents unintended side effects (a function could overwrite a wave's contents, for example). You can remove this limitation by creating the global variable root:V_debugDangerously and setting it to 1.

After You Find a Bug

Editing in the debugger window is disabled because the code is currently executing. Tracking down the routine after you've exited the debugger is easy if you follow these steps:

1) Scroll the debugger text pane back to the name of the routine you want to modify, and select it.
2) Control-click (*Macintosh*) or right-click (*Windows*) the name, and choose "Go to <routineName>" from the pop-up menu.
3) Exit the debugger by clicking the "Go" button or by pressing Escape.

Now the selected routine will be visible in the top procedure window, where you can edit it.

Debugger Shortcuts

Action	Shortcut
To enable debugger	Choose Enable Debugger from the Procedure menu or choose Enable Debugger from the procedure window's pop-up menu after Control-clicking (*Macintosh*) or right-clicking (*Windows*).
To automatically enter the debugger when an error occurs	Choose Debug on Error from the Procedure menu or choose Enable Debugger from a procedure window's pop-up menu after Control-clicking (*Macintosh*) or right-clicking (*Windows*).
To set or clear a breakpoint	Click in the left margin of the procedure window or click anywhere on the procedure window line where you want to set or clear the breakpoint and choose Set Breakpoint or Clear Breakpoint from a procedure window's pop-up menu after Control-clicking (*Macintosh*) or right-clicking (*Windows*).
To enable or disable a breakpoint	Shift-click a breakpoint in the left margin of the procedure window.
	Click anywhere on the procedure window line where you want to enable or disable the breakpoint and choose Enable Breakpoint or Disable Breakpoint procedure window's pop-up menu after Control-clicking (*Macintosh*) or right-clicking (*Windows*).
To execute the next command	On *Macintosh* press Enter, keypad Enter, or Return. For *Windows*, if no button has the focus, press Enter or Return. Otherwise, click the yellow arrow button.
To step into a subroutine	Press the +, =, or keypad + keys, or click the blue descending arrow button.
To step out of a subroutine to the calling routine	Press the -, _ (underscore) or keypad - keys, or click the blue ascending arrow button.
To resume executing normally	Press Escape (Esc), or click the green arrow button.

Action	Shortcut
To cancel execution	Click the red stop sign button.
To edit the value of a macro or function variable	Double-click the second column of the variables list, edit the value, and press Return or Enter.
To set the value of a function's string to null	Double-click the second column of the variables list, type "<null>" (without the quotes), and press Return or Enter.
To view the current value of a macro or function variable	Move the cursor to the procedure text of the variable name and wait. On *Macintosh*, the value appears to the right of the debugger buttons. On *Windows*, the value appears in a tooltip window.
To view the current value of an expression	Select the expression text with the cursor, position the cursor over the selection, and wait. (Expressions involving user-defined functions will not be evaluated unless V_debugDangerously is set to 1.)
To view global values in the current data folder	Choose "local and global variables" from the debugger pop-up menu.
To view type information about variables	Choose "show variable types" from the debugger pop-up menu.
To resize the columns in the variables list	Drag a divider in the list to the left or right.
To show or hide the Waves, Structs, and Expressions pane	Drag the divider on the right side of the Variables list left or right.

Chapter
IV-9

Dependencies

Dependency Formulas

Igor Pro supports "dependent objects". A dependent object can be a wave, a global numeric variable or a global string variable that has been linked to an expression. The expression to which an object is linked is called the object's "dependency formula" or "formula" for short.

The value of a dependent object is updated whenever any other global object involved in the formula is modified (even if its value stays the same). We say that the dependent object *depends* on these other global objects *through* the formula.

You might expect that an assignment such as:

```
wave1 = sin(K0*x/16)
```

meant that wave1 would be updated whenever K0 changed. It doesn't; values are computed for wave1 only once, and the relationship between wave1 and K0 is forgotten.

However, if the = in the above assignment is replaced with :=

```
wave1 := sin(K0*x/16)
```

then Igor *does* create just such a dependency. Now whenever K0 changes, the contents of wave1 will be updated. In this example, wave1 is a dependent object. It depends on K0, and sin(K0*x/16) is wave1's dependency formula.

You can also establish a dependency using the SetFormula operation, like this:

```
SetFormula wave1, "sin(K0*x/16)"
```

Wave1 depends on K0 because K0 is a changeable variable. Wave1 *also* depends on the function x (x is not a variable) that returns the X scaling of the destination wave (wave1). When the X scaling of wave1 changes, the values that the x function returns change, so this dependency assignment is reevaluated. The remaining terms (sin and 16) are not changeable, so wave1 does not depend on them.

Like other assignment statements, the data folder context for the right-hand side is that of the destination object. Therefore, in the following example, wave2 and var1 must be in the data folder named foo, var2 must be in root and var3 must be in root:bar.

```
root:foo:wave1 := wave2*var1 + ::var2 + root:bar:var3
```

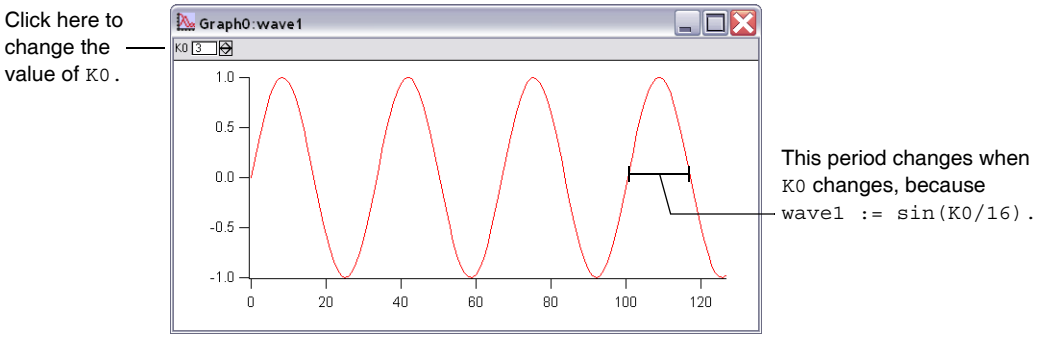
Data Folders are described inChapter II-8, **Data Folders**.

A dependency assignment is often used in conjunction with SetVariable controls (see page III-362) and Value Display controls (see page III-363).

Here's a simple example. Execute these commands on the command line:

```
K0=1
Make/O wave1:=sin(K0*x/16)
Display /W=(4,53,399,261) wave1
ControlBar 23
SetVariable setvar0,size={60,15},value=K0
```

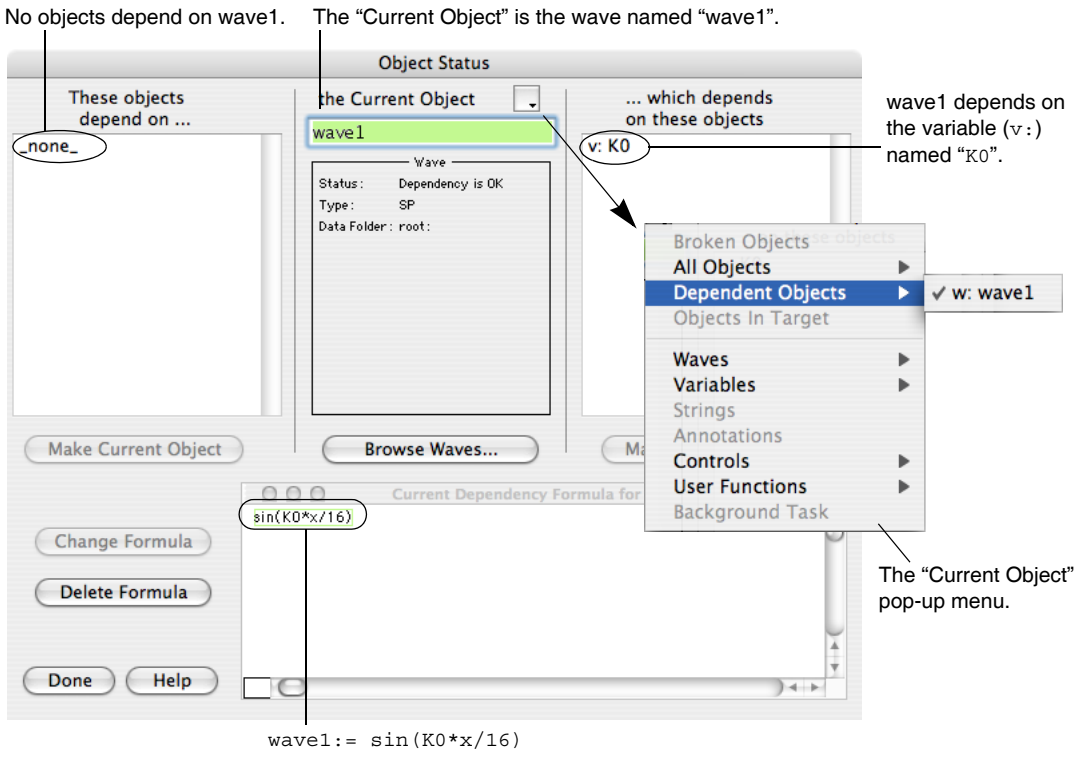
This results in the following graph:



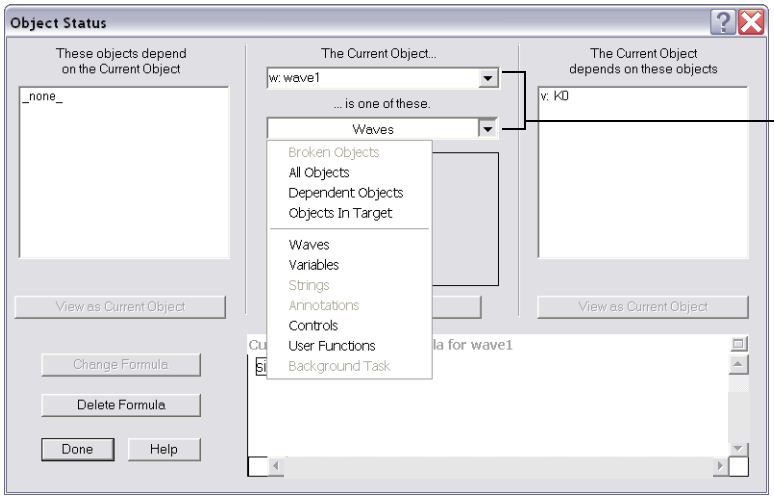
Click the SetVariable control's up and down arrows to adjust K0 and observe that wave1 is automatically updated.

Dependencies and the Object Status Dialog

You can use the Object Status dialog in the Misc menu to check dependencies. On the Macintosh, all dependent objects are listed in the Current Object pop-up menu under Dependent Objects:



The Windows version of the Object Status dialog is essentially the same but for a slightly different arrangement of the pop-up menus:



The Status field in the box below the current object name indicates any dependency status:

- "No dependency" means that the current object does not depend on anything.
- "Dependency is OK" means that the dependency formula successfully updated the current object.
- "Update failed" means that the dependency formula used to compute the current object's value failed, probably because there is a syntax error in the formula or one of the objects referenced in the formula does not exist or has been renamed. If an update fails, then the objects that depend on that update are broken and they appear in the Broken Objects submenu. See **Broken Dependent Objects** on page IV-206.

You can create a new dependency formula with the New Formula button, delete one with the Delete Formula button, change an existing one by typing in the Dependency Formula window and clicking the Change Formula button, and undo that change by clicking the Restore Formula button.

This is discussed further in **The Object Status Dialog** on page III-417.

You can also read the text of a dependency formula with the string function GetFormula, and set it with the operation SetFormula.

Numeric and String Variable Dependencies

Dependencies can also be created for global (but not local) user-defined numeric and string variables. Here is a user-defined function that creates a dependency (the global variable `recalculateThis` will depend on another global variable `dependsOnThis`):

```
Function TestRecalculation()
   Variable/G recalculateThis
   Variable/G dependsOnThis= 1

   // Create dependency on global variable
   SetFormula recalculateThis, "dependsOnThis"

   Print recalculateThis      // Prints original value

   dependsOnThis = 2          // Changes something recalculateThis

   DoUpdate                   // Make Igor recalculate formulae

   Print recalculateThis      // Prints updated value
End
```

Running this function prints the following to the history area:

```
•TestRecalculation()
   1
   2
```

The call to DoUpdate is needed because Igor recalculates dependency formulas only when no user-defined functions are running or when DoUpdate is called.

This function uses SetFormula to create the dependency because the := operator is not allowed in user-defined functions.

Note: You can not create a dependency *for* system numeric variables K0...K19 or veclen. You can create a dependency for something else *on* those variables, as in the first example of this chapter. In general, it is actually best if you do *not* use system variables in dependencies, since they are involved in Curve Fitting. You should define your own global variables for use in dependencies.

Wave Dependencies

The assignment statement:

dependentWaveName := *formula*

creates a dependency and links the dependency formula to the dependent wave. Whenever any change is made to any object in the formula, the contents of the dependent wave are updated.

The command

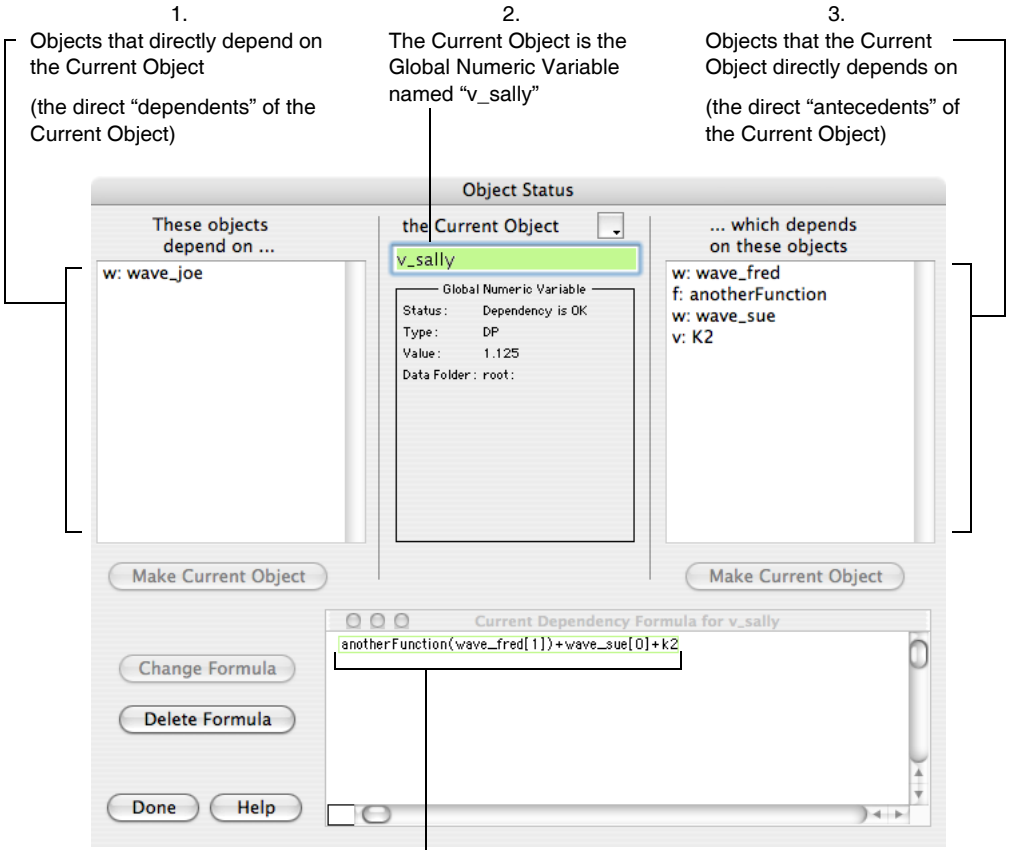
SetFormula *dependentWaveName*, "*formula*"

establishes the same dependency.

Cascading Dependencies

"Cascading dependencies" refers to the situation that arises when an object depends on a second object, which in turn depends on a third object, etc. When an object changes, all objects that directly depend on that object are updated, *and* objects that depend directly on those updated objects are updated until no more updates are needed.

The Object Status dialog shows three levels of dependency anchored on the Current Object:

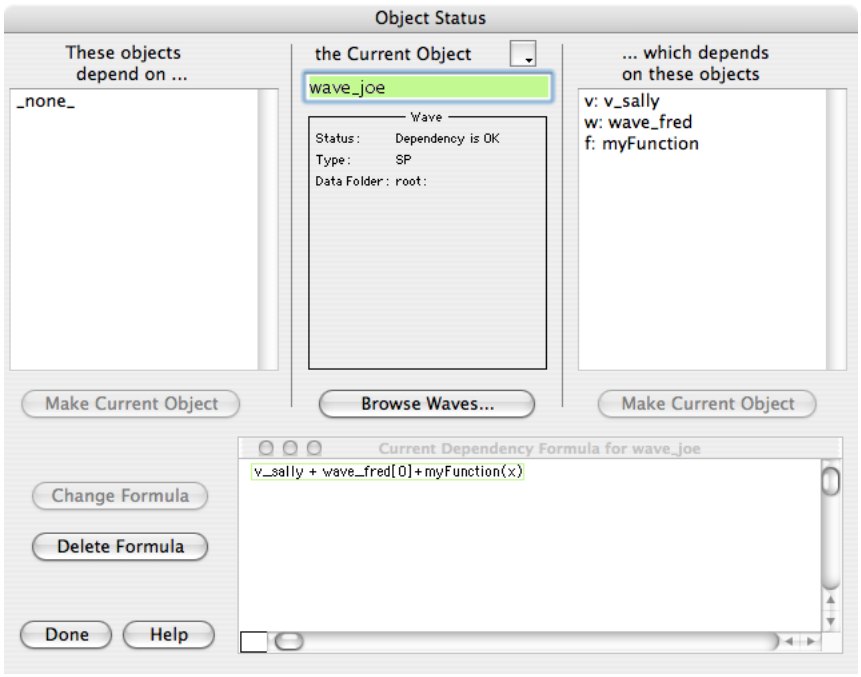


In this example, the current object is the global numeric variable v_sally. The only object directly dependent on v_sally is the wave wave_joe. V_sally directly depends on waves wave_fred and wave_sue, global numeric variable K2, and user-defined function anotherFunction. These dependencies exist because of the dependency assignment:

```
v_sally := anotherFunction(wave_fred[1]) + wave_sue[0] + K2
```

which can be changed or deleted with the dialog.

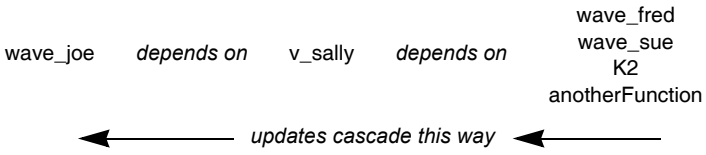
Wave_joe depends on v_sally for reasons that will become apparent only when wave_joe is made the current object:



The dependency was created by the dependency assignment:

```
wave_joe := v_sally + wave_fred[0]+myFunction(x)
```

Combining the dependency of wave_joe on v_sally with what v_sally depends on, you can see that wave_joe also *indirectly* depends on wave_sue, wave_fred, K2, and anotherFunction:



If you change K2, the dependencies will cascade so that v_sally and then wave_joe are updated. We call objects that wave_joe depends on directly or indirectly its "antecedents" (literally, "those that go before").

Deleting a Dependency

A dependency is deleted when the dependent object is assigned a value using the = operator:

```
recalculateThis := dependsOnThis    // creates dependency
recalculateThis = 0                 // deletes the dependency
```

This method of deleting a dependency does not work in user-defined functions. You must use the SetFormula operation.

For example:

```
Execute "recalculateThis = 0"
```

will delete the dependency even in a user-defined function.

You can also delete this dependency using the SetFormula operation.

```
SetFormula recalculateThis, ""
```

Wave dependencies are also deleted by operations that overwrite the values of their wave parameters. Some of these operations are:

```
FFT       Convolve        Correlate    Smooth    GraphWaveEdit
Hanning   Differentiate   Integrate    UnWrap
```

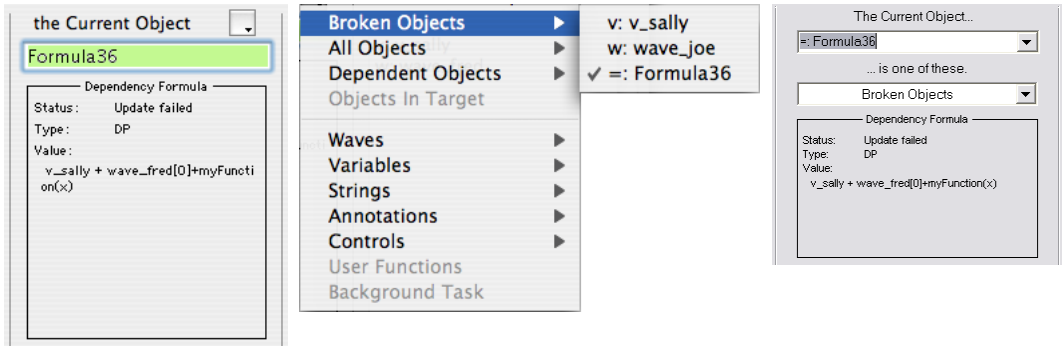
Dependencies can also be deleted via the Object Status dialog in the Misc menu.

Broken Dependent Objects

Igor compiles the text of a dependency formula to low-level code and stores both the original text and the low-level code with the dependent object. At various times, Igor may need to recompile the dependency formula text. At that time it is possible to get a compilation error if one of the objects in the formula has been renamed or deleted, or if the formula contains a syntax error.

When this happens, the dependent object will no longer update but will retain its last value. We call such an object "broken". If you suspect this kind of problem has happened, invoke the Object Status dialog using the Misc menu.

Any such broken objects will show up in the Broken Objects submenu of the Current Object pop-up menu:



When Dependencies are Updated

Dependency updates take place at the same time that graphs are updated. This happens after each line in a macro is executed, or when DoUpdate is called from a macro or user function, or continuously if a macro or function is not running.

Dependency formulas used as input to the SetBackground and ValDisplay operations, and in some other contexts, can alternately be specified as a literal string of characters using the following syntax:

```
#"text_of_the_dependency_expression"
```

Note that what follows the # char must be a literal string — not a string expression.

This will set the dependency formula *without* compiling it or checking it for validity. It is mainly for use internally but if you find yourself in a situation where you need to set the dependency formula of an object to something that is not currently valid but will be in the future then feel free to use this alternate method.

Programming with Dependencies

You cannot use := to create dependencies in user-defined functions. Instead you must use the **SetFormula** operation (see page V-559).

```
Function TestFunc()
   Variable/G varNum=-666
   Make wave1
   SetFormula wave1, "varNum"    // Equivalent to wave1 := varNum
End
```

Using Operations in Dependency Formulas

The dependency formula must be a single expression — and you can not use operations, such as FFT's, or other command type operations. However, you can invoke user-defined functions which *in turn* invoke operations:

```
Function MakeDependencyUsingOperation()
   Make/O/N=128 data = p         // A ramp from 0 to 127
   Variable/G power

   SetFormula power, "RMS(data)" // Dependency on function and wave
   Print power

   data = p * 2                  // Changes something power depends
   DoUpdate                      // Make Igor recalc formulae
   Print power
EndMacro

Function RMS(w)
   Wave w

   WaveStats/Q w           // An operation! One output is V_rms
   return V_rms
End
```

When `MakeDependencyUsingOperation` is executed, it prints the following in the history area:

```
•MakeDependencyUsingOperation()
   73.4677
   146.935
```

Dependency Caveats

The extensive use of dependencies can create a confusing tangle that can be difficult to manage. Although you can use the Object Status dialog to explore the dependency hierarchy, you can still become very confused very quickly, especially when the dependencies are highly cascaded. You should use dependencies only where they are needed. Use conventional assignments for the majority of your calculations.

There is no built-in limit to the depth of dependency cascading except that speed considerations will limit the depth to about 20. Similarly there will be a practical limit to the total number of objects with dependencies. The actual limit can not be specified in advance.

Dependency formulas are generally not recalculated when a user-defined function is running unless you explicitly call the DoUpdate operation. However, they can run at other hard to predict times (especially on Windows) and you should not make any assumptions as to the timing or the current data folder when they run.

The text of the dependency formula that is saved for a dependent object is the original literal text. The dependency formula needs to be recompiled from time to time, for example when procedures are compiled. Therefore, any objects used in the formula must persist until the formula is deleted.

We recommend that you never use $ expressions in a dependency formula.

Chapter

IV-10

Advanced Programming

This chapter contains usage notes on a number of advanced programming topics.

Regular Modules

Regular modules, or "modules" for short, provide a way to avoid name conflicts between procedure files. Regular modules are distinct from "independent modules" which are discussed in the next section.

By default, a procedure file is in the built-in ProcGlobal module. A procedure file that does not contain a #pragma ModuleName statement (or a #pragma IndependentModule statement - discussed below) is in ProcGlobal. Neither #pragma ModuleName nor #pragma IndependentModule are allowed in the built-in procedure window which is always in ProcGlobal.

When you execute a function from the command line or use the **Execute** operation, you are operating in the ProcGlobal context.

Functions in ProcGlobal are either public, or, if they are declared using the static keyword, private. For example:

```
// In a procedure file with no #pragma ModuleName or #pragma IndependentModule

static Function Test()           // Private to its procedure file
   Print "Test in ProcGlobal"
End

Function TestInProcGlobal()      // Public
   Print "TestInProcGlobal in ProcGlobal"
End
```

Because it is declared static, the Test function is private to the procedure file containing it. Each procedure file can have its own static Test function without causing a name conflict. The TestInProcGlobal function is public so there can be only one public function with this name.

In this example the static Test function is accessible only from the procedure file in which it is defined. Sometimes you have a need to avoid name conflicts but still want to be able to call functions from other procedure files, from control action procedures or from the command line. This is where a regular module is useful.

You specify that a procedure file is in a different module (other than ProcGlobal) using the ModuleName pragma. For example:

```
#pragma ModuleName = ModuleA     // The following procedures are in ModuleA

static Function Test()           // Semi-private
   Print "Test in ModuleA"
End

Function TestModuleA()           // Public
   Print "Test in ModuleA"
End
```

Because it is declared static, this Test function will not cause name conflicts with other modules, including the ProcGlobal module. In this sense, it is private. But because it is in a named regular module (ModuleA), it can be called from other procedure files using a qualified name:

```
ModuleA#Test()                   // Call Test from ModuleA
```

This qualified name syntax overrides the static nature of Test and tells Igor that you want to execute the Test function defined in ModuleA. The only way to access a static function from another procedure file is to put it in a regular module and use a qualified name.

If you are writing a non-trivial set of procedures, it is a good idea to use a module and to declare your functions static, especially if other people will be using your code. This prevents name conflicts with other procedures that you or other programmers write. Make sure to choose a distinctive module name.

Regular Modules in Action Procedures and Hook Functions

Control action procedures and hook functions are called by Igor at certain times. They are executed in the ProcGlobal context. This means that a static function can not be used as an action procedure or a hook function without using a qualified name. For example:

```
// In a procedure file with no #pragma ModuleName or #pragma IndependentModule

static Function ButtonProc(ba) : ButtonControl
   STRUCT WMButtonAction &ba

   switch (ba.eventCode)
      case 2: // mouse up
         Print "Running ProcGlobal#ButtonProc"
         break
   endswitch

   return 0
End

Function CreatePanel()
   NewPanel /W=(375,148,677,228)
   // This will not work because ButtonProc is private to the procedure file
   Button button0,pos={106,23},size={98,20},title="Click Me"
   Button button0,proc=ButtonProc
End
```

When you click the Click Me button, Igor tries to run the ButtonProc action procedure. However, because it is static, it is not accessible from outside the procedure file so Igor displays an error.

There are two possible solutions for this problem:

1. Make ButtonProc global by removing the static keyword

2. Use a regular module

If you make ButtonProc global, you run the risk of a name conflict with some other programmer's ButtonProc function. You can prevent this by changing ButtonProc to a very distinctive name, like AcmeDataAcqButtonProc, but this becomes tedious.

Here is the solution using a module:

```
#pragma ModuleName = RegularModuleA

static Function ButtonProc(ba) : ButtonControl
   STRUCT WMButtonAction &ba

   switch (ba.eventCode)
      case 2: // mouse up
         Print "Running RegularModuleA#ButtonProc"
         break
   endswitch

   return 0
End

static Function CreatePanel()
   NewPanel /W=(375,148,677,228)
```

```
   Button button0,pos={106,23},size={98,20},title="Click Me"
   Button button0,proc=RegularModuleA#ButtonProc
End
```

RegularModuleA is the name we have chosen for the regular module for demonstration purposes. You should choose a more descriptive module name.

The use of a qualified name, RegularModuleA#ButtonProc, allows Igor to find and execute the static ButtonProc function in the RegularModuleA module even though ButtonProc is running in the ProcGlobal context.

To protect the CreatePanel function from name conflicts we also made it static. To create the panel, execute:

```
RegularModuleA#CreatePanel()
```

Regular Modules and User-Defined Menus

Menu item execution text also runs in the ProcGlobal context. If you want to call a routine in a regular module you must use a qualified name.

Continuing the example from the preceding section, here is how you would write a menu definition:

```
#pragma ModuleName = RegularModuleA

Menu "Macros"
   "Create Panel", RegularModuleA#CreatePanel()
End
```

See also **Independent Modules** below, **Controls and Control Panels** on page III-357, **User-Defined Hook Functions** on page IV-251 and **User-Defined Menus** on page IV-105.

Independent Modules

An independent module is a set of procedure files that are compiled separately from all other procedures. Because it is compiled separately, an independent module can run when other procedures are in an uncompiled state because the user is editing them or because an error occurred in the last compile. This allows the independent module's control panels and menus to continue to work regardless of user programming errors.

Creating an independent module adds complications and requires a solid understanding of Igor programming. You should use an independent module if it is important that your procedures be runnable at all times. For example, if you have created a data acquisition package that must run regardless of what the user is doing, that would be a good candidate for an independent module.

A file is designated as being part of an independent module using the IndependentModule pragma:

```
#pragma IndependentModule = imName
```

Make sure to use a distinctive name for your independent module.

The IndependentModule pragma is not allowed in the built-in procedure window which is always in the ProcGlobal module.

An independent module creates an independent namespace. Function names in an independent module do not conflict with the same names used in other modules. To call an independent module function from another module, including the default ProcGlobal module, the function must be public (non-static) and you must use a qualified name as illustrated in the next section.

Independent Modules - A Simple Example

Here is a simple example using an independent module. This code must be in its own procedure file and not in the built-in procedure file:

```
#pragma IndependentModule = IndependentModuleA

static Function Test()              // static means private to file
   Print "Test in IndependentModuleA"
End

// This must be non-static to call from command line (ProcGlobal context)
Function CallTestInIndependentModuleA()
   Test()
End
```

From the command line (the ProcGlobal context):

```
CallTestInIndependentModuleA()                      // Error

IndependentModuleA#CallTestInIndependentModuleA()   // OK

IndependentModuleA#Test()                           // Error
```

The first command does not work because the functions in the independent module are accessible only using a qualified name. The second command does work because it uses a qualified name and because the function is public (non-static). The third command does not work because the function is private (static) and therefore is accessible only from the file in which it is defined. A static function in an independent module is not accessible from outside the procedure file in which it is defined unless it is in an enclosed regular module as described under **Regular Modules Within Independent Modules** on page IV-218.

SetIgorOption IndependentModuleDev=1

By default, the debugger is disabled for independent modules. It can be enabled using:

```
SetIgorOption IndependentModuleDev=1
```

Also by default, independent module procedure windows that are read-only or write-protected are not listed in the Windows→Procedure Windows submenu unless you use `SetIgorOption IndependentModuleDev=1`.

Procedures loaded from "Igor Pro Folder/Igor Procedures" and "Igor Pro User Files/Igor Procedures" or those loaded via the #include mechanism are write-protected and therefore are not visible until you execute `SetIgorOption IndependentModuleDev=1`.

When `SetIgorOption IndependentModuleDev=1` is in effect, the Windows→Procedure Windows submenu shows all procedure windows, and those that belong to an independent module are listed with the independent module name in brackets:

This syntax is used in the **WinList**, **FunctionList**, **DisplayProcedure**, and **ProcedureText** functions and operations.

To get the user experience, as opposed to the programmer experience, return to normal operation by executing:

```
SetIgorOption IndependentModuleDev=0
```

Independent Module Development Tips

Development of an independent module may be easier if it is first done as for normal code. Add the module declaration

```
#pragma IndependentModule = moduleName
```

only after the code has been fully debugged and is working properly.

A procedure file that is designed to be #included should ideally work inside or outside of an independent module. Read the sections on independent modules below to learn what the issues are.

When programming an independent module, you will usually want to execute:

```
SetIgorOption IndependentModuleDev=1
```

Independent Modules and #include

If you #include a procedure file from an independent module, Igor copies the #included file into memory and makes it part of the independent module by inserting a #pragma IndependentModule statement at the start of the copy. If the same file is included several times, there will be several copies, each with a different independent module name.

Warning: Do not edit the procedure windows created by #including into an independent module because they are temporary and your changes will not be saved. You would not want to save them anyway because Igor has modified them.

Warning: Do not #include files that already contain a #pragma IndependentModule statement unless the independent module name is the same.

Limitations of Independent Modules

Independent modules are not for every-day programming and are somewhat more difficult to create than normal modules because of the following limitations:

1. Macros and Procs are not supported.
2. Button and control dialogs do not list functions in an independent module.
3. Functions in an independent module can not call functions in other modules except through the Execute operation.
4. The IndependentModule pragma requires Igor Pro 6 or later.

Independent Modules in Action Procedures and Hook Functions

Normally you must use a qualified name to invoke a function defined in an independent module from the ProcGlobal context. Control action procedures and hook functions execute in the ProcGlobal context. But, as a convenience and to make #include files more useful, Igor eliminates this requirement when you create controls and specify hook functions from a user-defined function.

When you execute an operation that creates a control or specifies a hook function while running in an independent module, Igor examines the specified control action function name or hook function name. If the named function is defined in the same independent module, Igor automatically inserts the independent module name. This means you can write something like:

```
#pragma IndependentModule = IndependentModuleA
Button b0, proc=ButtonProc
SetWindow hook(Hook1)=HookFunc
```

You don't have to write:

```
#pragma IndependentModule = IndependentModuleA
Button b0, proc=IndependentModuleA#ButtonProc
SetWindow hook(Hook1)=IndependentModuleA#HookFunc
```

Such independent module name insertion is only done when an operation called from a function defined in an independent module. It is not done if the operation is executed from the command line or via **Execute**.

The control action function or hook function must be public (non-static) (except as describe under **Regular Modules Within Independent Modules** on page IV-218).

Here is a working example:

```
#pragma IndependentModule = IndependentModuleA

Function ButtonProc(ba) : ButtonControl   // Must not be static
   STRUCT WMButtonAction &ba

   switch (ba.eventCode)
      case 2: // mouse up
         Print "Running IndependentModuleA#ButtonProc"
         break
   endswitch

   return 0
End

Function CreatePanel()
   NewPanel /W=(375,148,677,228)
   Button button0,pos={106,23},size={98,20},title="Click Me"
   Button button0,proc=ButtonProc
End
```

Independent Modules and User-Defined Menus

Independent modules can contain user-defined menus. When you choose a user-defined menu item, Igor determines if the menu item was defined in an independent module. If so, and if the menu item's execution text starts with a call to a function defined in the independent module, then Igor prepends the independent module name before executing the text. This means that the second and third menu items in the following example both call IndependentModuleA#DoAnalysis:

```
#pragma IndependentModule = IndependentModuleA

Menu "Macros"
   "Load Data File/1", Beep; LoadWave/G
   "Do Analysis/2", DoAnalysis() // Igor automatically prepends IndependentModuleA#
   "Do Analysis/3", IndependentModuleA#DoAnalysis()
End

Function DoAnalysis()
   Print "DoAnalysis in IndependentModuleA"
End
```

This behavior on Igor's part makes it possible to #include a procedure file that creates menu items into an independent module and have the menu items work. However, in many cases you will not want a #included file's menu items to appear. You can suppress them using `menus=0` option in the #include statement. See **Turning the Included File's Menus Off** on page IV-146.

Note: If a procedure file with menu definitions is included into multiple independent modules, the menus are repeatedly defined (see **Independent Modules and #include** on page IV-216). Judicious use of the menus=0 option in the #include statements helps prevent this. See **Turning the Included File's Menus Off** on page IV-146.

When the execution text doesn't start with a user-defined function name, as for the first menu item in this example, Igor executes the text without altering it.

Independent Modules and Popup Menus

In an independent module, implementing a popup menu whose items are determined by a function call at click time requires special care. For example, outside of an independent module, this works:

```
Function/S myPopMenuList()
   return "item 1;item2;"
End
...
PopupMenu pop0 value=#"myPopMenuList()"      // Note the quotation marks
```

But inside an independent module you need this:

```
#pragma IndependentModule=myIM
Function/S myPopMenuList()
   return "item 1;item2;"
End
...
String cmd= GetIndependentModuleName()+"#myPopMenuList()"
PopupMenu pop0 value=#cmd                    // No enclosing quotation marks
```

GetIndependentModuleName returns the name of the independent module to which the currently-running function belongs or "ProcGlobal" if the currently-running function is not part of an independent module.

You could change the command string to:

```
PopupMenu pop0 value=#"myIM##myPopMenuList()"
```

but using GetIndependentModuleName allows you to disable the IndependentModule pragma by commenting it out and have the code still work which can be useful during development. With the pragma commented out you are running in ProcGlobal context and GetIndependentModuleName returns "ProcGlobal".

When the user clicks the popup menu, Igor generates the menu items by evaluating the text specified by the PopupMenu value keyword as an Igor expression. The expression (`"myIM#myPopMenuList()"` in this case) is evaluated in the ProcGlobal context. In order for Igor to find the function in the independent module, it must be public (non-static) (except as describe under **Regular Modules Within Independent Modules** on page IV-218) and you must use a qualified name.

Note that `#cmd` is not the same as `#"cmd"`. The `#cmd` form was introduced with Igor Pro 6. The string variable cmd is evaluated when PopupMenu runs which occurs in the context of the independent module. The contents of cmd (`"myIM#myPopMenuList()"` in this case) are stored in the popup menu's internal data structure. When the popup menu is clicked, Igor evaluates the stored text as an Igor expression. This causes the function `myIM#myPopMenuList` to run.

With the older `#"cmd"` syntax, the stored text is evaluated only when the popup menu is clicked, not when the PopupMenu operation runs, and this evaluation occurs in the ProcGlobal context. It is too late to capture the independent module in which the text should be evaluated.

Regular Modules Within Independent Modules

It is usually not necessary but you can create a regular module within an independent module. For example:

```
#pragma IndependentModule = IndependentModuleA
#pragma ModuleName = RegularModuleA
Function Test()
   Print "Test in RegularModuleA within IndependentModuleA"
End
```

Here RegularModuleA is a regular module within IndependentModuleA.

To call the function Test from outside of the independent module you must qualify the call like this:

```
IndependentModuleA#RegularModuleA#Test()
```

This illustrates that the independent module establishes its own namespace (IndependentModuleA) which can host one level of sub-namespace (RegularModuleA). By contrast, a regular module creates a namespace within the global namespace (called ProcGlobal) and can not host additional sub-namespaces.

This nesting of modules is useful to prevent name conflicts in a large independent module project comprising multiple procedure files. Otherwise it is not necessary.

Because all procedure files in a given independent module are compiled separately from all other files, function names never conflict with those outside the group and there is little or no need to use the static designation on functions in an independent module. However, if need be, you can call static functions in a regular module inside an independent module from outside the independent module using a triple-qualified name:

IndependentModuleName#*RegularModuleName*#*FunctionName*()

Calling Routines From Other Modules

Code in an independent module can not directly call routines in other modules and usually should not need to. If you must call a routine from another module, you can do it using the **Execute** operation. You must use a qualified name. For example:

```
Execute "ProcGlobal#foo()"
```

To call a function in a regular module, you must prepend ProcGlobal and the regular module name to the function name:

```
Execute "ProcGlobal#MyRegularModule#foo()"
```

Calling a nonstatic function in a different independent modules requires prepending just the other independent module name:

```
Execute "OtherIndependentModule#bar()"
```

Calling static functions in other independent modules requires prepending the independent module name and a regular module name:

```
Execute "OtherIndependentModule#RegularModuleName#staticbar()"
```

Using Execute Within an Independent Module

If you need to call a function in the current independent module using Execute, you can compose the name using the **GetIndependentModuleName** function. For example, outside of an independent module the commands would be:

```
String cmd = "WS_UpdateWaveSelectorWidget(\"Panel0\", \"selectorWidgetName\")"
Execute cmd
```

But inside an independent module the commands are:

```
#pragma IndependentModule=myIM
String cmd="WS_UpdateWaveSelectorWidget(\"Panel0\", \"selectorWidgetName\")"
cmd = GetIndependentModuleName() + "#" + cmd    // Make qualified name
Execute cmd
```

You could change the command string to:

```
cmd = "myIM#" + cmd
```

but using GetIndependentModuleName allows you to disable the IndependentModule pragma by commenting it out and have the code still work which can be useful during development. With the pragma commented out you are running in ProcGlobal context and GetIndependentModuleName returns "ProcGlobal".

Independent Modules and Dependencies

GetIndependentModuleName is also useful for defining dependencies using functions in the current independent module. Dependencies are evaluated in the global procedure context (ProcGlobal). In order for dependencies to evaluate correctly, the dependency must use GetIndependentModuleName to create a formula to pass to the **SetFormula** operation. For example, outside of an independent module, this works:

```
String formula = "foo(root:wave0)"
SetFormula root:aVariable $formula
```

But inside an independent module you need this:

```
#pragma IndependentModule=myIM
String formula = GetIndependentModuleName() + "#foo(root:wave0)"
SetFormula root:aVariable $formula
```

Independent Modules and Pictures

To allow DrawPICT to use a picture in the picture gallery, you must prepend GalleryGlobal# to the picture name:

```
DrawPICT 0,0,1,1,GalleryGlobal#PICT_0
```

Without GalleryGlobal, only Proc Pictures can be used defined in an independent module. GalleryGlobal is available in Igor Pro 6.1 or later.

Making Regular Procedures Independent-Module-Compatible

You may want to make an existing set of procedures into an independent module. Alternatively, you may want to make an existing procedure independent-module-compatible so that it can be #included into an independent module. This section outlines the necessary steps.

1. If you are creating an independent module, add the IndependentModule pragma:

   ```
   #pragma IndependentModule=<NameOfIndependentModule>
   ```

2. Change any Macro or Proc procedures to functions.
3. Make Execute commands suitable for running in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Using Execute Within an Independent Module** on page IV-219.
4. Make PopupMenu controls that call a string function to populate the menu work in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Independent Modules and Popup Menus** on page IV-218.
5. Make any dependencies work in the ProcGlobal context or in an independent module using GetIndependentModuleName. See **Independent Modules and Dependencies** on page IV-220.

See also **Regular Modules** on page IV-212, **Controls and Control Panels** on page III-357, **User-Defined Hook Functions** on page IV-251, **User-Defined Menus** on page IV-105, and **GetIndependentModuleName** on page V-214.

Sound

Two operations are provided for playing of sound through the computer speakers:

- PlaySound
- PlaySnd (*Macintosh*)

The **PlaySound** operation takes the sound data from a wave.

The obsolete **PlaySnd** operation gets its data from a Macintosh 'snd ' resource stored in a file.

A number of sound input operations are provided: **SoundInStatus** (page V-583) , **SoundInSet** (page V-583) , **SoundInRecord** (page V-582) , **SoundInStartChart** (page V-583) and **SoundInStopChart** (page V-584) . Several example experiments that use these routines can be found in your Igor Pro Folder in the Examples folder.

The SndLoadSaveWave XOP loads and saves various sound file formats into and from waves. It also adds a Load Sound File menu item to the Load Waves submenu and a Save Sound File menu item to the Save Waves submenu as well as several command line operations. See the SndLoadSaveWave help file in the More Extensions:File Loaders folder for details.

Movies

If you have Apple's QuickTime installed on your computer, you can create or play movies. You can even add a soundtrack to your movies.

The process of creating a movie is very simple. You use the following operations to create a new movie file, add video frames and audio, close the file and then play the movie. Refer to Chapter V-1, **Igor Reference**, for details on the operations.

- NewMovie
- AddMovieFrame
- AddMovieAudio
- CloseMovie
- PlayMovie
- PlayMovieAction

The NewMovie operation creates a movie file and also defines the movie frame rate and optional audio track specifications. Before calling NewMovie, you need to prepare the first frame of your movie as the target graph. If you will be using audio you also need to prepare a sound wave. The sound wave can be of any time duration but usually will either be the entire length of the movie or will be the length of one video frame. If you will be placing your movie on a Web page or transferring it across platforms, be sure to use the /L flag with NewMovie to create a "flattened" movie.

After creating the file and the first video frame and optional audio, you use AddMovieFrame to add as many video frames as you wish. You may also add more audio using the AddMovieAudio operation. Finally you use the CloseMovie and PlayMovie operations.

When you write a procedure to generate a movie, you need to call the DoUpdate operation after all modifications to the graph and before calling AddMovieFrame. This allows Igor to process any changes you have made to the graph.

You may use the PlayMovie operation to play any QuickTime movie — not just those you create with Igor.

You can extract individual frames from a movie and can control movie playback using PlayMovieAction.

For examples of programming with movies, see the Examples:Movies & Audio folder.

Timing

There are two methods you can use when you want to measure elapsed time:

- The ticks counter using the ticks function
- The microsecond timer using StartMSTimer() and StopMSTimer()

Ticks Counter

You can easily measure elapsed time with a precision of 1/60th of a second using the ticks function. It returns the tick count which starts at zero when you first start your computer and is incremented at a rate of approximately 60 Hz rate from then on.

Here is an example of typical use:

```
…
Variable t0
…
t0= ticks
<operations you wish to time>
printf "Elapsed time was %g seconds\r",(ticks-t0)/60
…
```

Microsecond Timer

You can measure elapsed time to microsecond accuracy for durations up to 35 minutes using the microsecond timer. See the **startMSTimer** function (page V-594) for details and an example.

Packages

A package is a set of files that adds a significant set of functionality to Igor. Packages consist of procedure files and may also include XOPs, help files and other supporting files.

A package usually adds one or more items to Igor's menus that allow the user to interactively load the package, access its functionality, and unload the package.

A package typically provides some level of user-interface, such as a menu item and a control panel, for accessing the added functionality. It may store settings in experiments or in global preferences.

A package is typically loaded into memory and unloaded at the user's request.

Igor comes pre-configured with numerous WaveMetrics packages accessed through the Data→Packages, Analysis→Packages, Misc→Packages, Windows→New→Packages and Graph→Packages submenus as well as others. Take a peek at these submenus to see what packages are supplied with Igor.

Menu items for WaveMetrics packages are added to Igor's menus by the WMMenus.ipf procedure file which is shipped in the Igor Procedures folder. (WMMenus.ipf is hidden unless you enable independent module development. See **Independent Modules** on page IV-214.)

A large package of 3D-plotting support routines is accessible through the Gizmo menu that appears in the main menu bar when a Gizmo 3D window is active.

The following section explains how to add a package to Igor.

Creating a Package

This section shows how to create a package through a simple example. The package is called "Sample Package". It adds a Load Sample Package item to the Macros menu. When the user chooses Load Sample Package, the package's procedure file is loaded. This adds two additional items to the Macros menu: Hello From Sample Package and Unload Sample Package.

The package consists of two procedure files stored in a folder in the Igor Pro User Files folder. If you are not familiar with Igor Pro User Files, take a short detour and read **Special Folders** on page II-44 and **Igor Pro User Files** on page II-46.

The sample package is installed as follows:

```
Igor Pro 6 User Files
   Sample Package
```

```
      Sample Package Loader.ipf
      Sample Package.ipf
   Igor Procedures
      Alias or shortcut pointing to the "Sample Package Loader.ipf" file
   User Procedures
      Alias or shortcut pointing to the "Sample Package" folder
```

Putting the alias/shortcut for the "Sample Package Loader.ipf" in Igor Procedures causes Igor to load that file at launch time. The file adds the "Load Sample Package" item to the Macros menu. (See **Global Procedure Files** on page III-345 for details.)

Putting the alias/shortcut for the "Sample Package" folder in User Procedures causes Igor to search that folder when a #include is invoked. (See **Shared Procedure Files** on page III-345 for details.)

A real package might include other procedure files and a help file in the "Sample Package" folder.

To try this out yourself, follow these steps:

1. Create the "Sample Package" folder in your Igor Pro User Files folder.

   You can locate your Igor Pro User Files folder using the Help menu.

2. Create a new procedure file named "Sample Package Loader.ipf" in the "Sample Package" folder and enter the following contents in the file:

   ```
   Menu "Macros"
      "Load Sample Package", /Q, LoadSamplePackage()
   End

   Function LoadSamplePackage()
      Execute/P/Q/Z "INSERTINCLUDE \"Sample Package\""
      Execute/P/Q/Z "COMPILEPROCEDURES "// Note the space before final quote
   End
   ```

   Save the procedure file.

3. Create a new procedure file named "Sample Package.ipf" in the "Sample Package" folder and enter the following contents in the file:

   ```
   Menu "Macros"
      "Hello From Sample Package", HelloFromSamplePackage()
      "Unload Sample Package", UnloadSamplePackage()
   End

   Function HelloFromSamplePackage()
      DoAlert /T="Sample Package Wants to Say" 0, "Hello!"
   End

   Function UnloadSamplePackage()
      Execute /P /Q /Z "DELETEINCLUDE \"Sample Package\""
      Execute /P /Q /Z "COMPILEPROCEDURES "// Note the space before final quote
   End
   ```

   Save the procedure file.

4. In the desktop, make an alias or shortcut for "Sample Package Loader.ipf" file and put it in the Igor Procedures folder in the Igor Pro User Files folder.

   This causes Igor to load the "Sample Package Loader.ipf" file at launch time. This is how the Load Sample Package menu item gets into the Macros menu.

5. In the desktop, make an alias or shortcut for the "Sample Package" folder and put it in the User Procedures folder in the Igor Pro User Files folder.

   This causes Igor to search the "Sample Package" folder when a #include is invoked. This allows Igor to find the "Sample Package.ipf" file when it is #included.

6. Quit and restart Igor so that Igor will load the "Sample Package Loader.ipf" file.

   If you prefer you can just manually make sure that "Sample Package Loader.ipf" is open and "Sample Package.ipf" is closed. This simulates the state of affairs after restarting Igor.

7. Choose Windows→Procedure Windows and verify that Igor has loaded the "Sample Package Loader.ipf" file.

8. Click the Macros menu and verify that the "Load Sample Package" item is present.

9. Choose Macros→Load Sample Package.

   The LoadSamplePackage function runs, adds a #include statement to the built-in procedure window, and forces procedures to be recompiled. This cause Igor to load the "Sample Package.ipf" procedure file which contains the bulk of the package's procedures and adds items to the Macros menu.

10. Click the Macros menu and notice that the "Hello From Sample Package" and "Unload Sample Package" items have been added.

11. Choose Macros→Hello From Sample Package.

    The package displays an alert. A real package would do something more exciting.

12. Choose Macros→Unload Sample Package.

    The UnloadSamplePackage function runs, removes the #include statement from the built-in procedure window, and forces procedures to be recompiled. This cause Igor to unload the "Sample Package.ipf" procedure.

13. Click the Macros menu and notice that the "Hello From Sample Package" and "Unload Sample Package" items have been removed.

Most real packages do not create Unload menu items. Instead they provide an Unload Package button in a control panel or automatically unload when a control panel is closed. Or they might not support unloading.

A real package typically does not include "Package" in its name or in its menu items.

Lightweight Packages

A lightweight package is one that consists of at most a few procedure files and does not create clutter in the current experiment unless it is actually used.

If your package is lightweight you might prefer to dispense with loading and unload it and just keep it loaded all the time. To do this you would organize your files like this:

```
Igor Pro 6 User Files
   Your Package
      Your Package Part 1.ipf
      Your Package Part 2.ipf
   Igor Procedures
      Alias or shortcut pointing to the "Your Package" folder
```

Here both of your package procedure files are global, meaning that Igor loads them at launch time and never unloads them. You do not need procedures for loading and unloading your package.

If you have an ultra-light package, consisting of just a single procedure file, you can dispense with the "Your Package" folder and put the procedure file directly in the Igor Procedures folder.

Managing Package Data

When you create a package of procedures, you need some place to store private data used by the package to keep track of its state. It's important to keep this data separate from the user's data to avoid clutter and to protect your data from inadvertent changes.

Private data should be stored in a data folder named after the package inside a generic data folder named Packages. For example, if your package is named My Package you would store your private data in `root:Packages:My Package`.

There are two general types of private data that you might need to store: overall package data and per-instance data. For example, for a data acquisition package, you may need to store data describing the state of the acquisition as a whole and other data on a per-channel basis.

Creating Globals in a Specific Data Folder

Here is an example of creating the overall private data for a package:

```
Function CreatePackageData()
   // Create the package data folder if it does not already exist
   NewDataFolder/O root:Packages
   NewDataFolder/O root:Packages:'My Package'

   // Create a data folder reference variable
   DFREF dfr = root:Packages:'My Package'

   Make dfr:wave1
   Variable/G dfr:gVar1
   String/G dfr:gStr1

   WAVE wave1 = dfr:wave1
   NVAR var1 = dfr:gVar1
   SVAR str1 = dfr:gStr1

   wave1= x^2
   var1= 1
   str1= "hello"
End
```

Creating Globals In A Per-Instance Data Folder

In the previous example, the absolute path to the data folder was known at the time the functions were written. This is the case when there is only one such data folder.

In other cases, there may be many data folders with different names containing the same waves and variables. Each data folder represents an instance of a particular object.

For example, if you write a data acquisition package that deals with multiple data acquisition boards, you will probably want to store a set of data for each board with each set in its own data folder. Here is an example of a function that creates globals for a particular instance of the data acquisition board:

```
Function CreateBoardGlobals(boardName)
   String boardName     // e.g., "DAQ 1", DAQ 2", . . .

   NewDataFolder/O root:Packages
   NewDataFolder/O root:Packages:'My Package'
   NewDataFolder/O root:Packages:'My Package':$boardName

   // Create a data folder reference variable
   DFREF dfr = root:Packages:'My Package':$boardName

   Variable/G dfr:gBoardGain = 1
   String/G dfr:gBoardStatusStr = "OK"
End
```

Here the $ operator is used to convert the boardName string into a data folder name used for the per-instance data folder.

Saving Package Preferences

If you are writing a sophisticated package of Igor procedures you may want to save preferences for your package. For example, if your package creates a control panel that can be opened in any experiment, you may want it to remember its position on screen between invocations. Or you may want to remember various settings in the panel from one invocation to the next.

Such "state" information can be stored either separately in each experiment or it can be stored just once for all experiments in preferences. These two approaches both have their place, depending on circumstances. But if your package creates a control panel that is intended to be present at all times and used in any experiment then the preferences approach is usually the best fit.

If you choose the preferences approach, you will store your package preference file in a directory created for your package. Your package directory will be in the Packages directory, inside Igor's own preferences directory.

The location of Igor's Packages directory depends on the operating system and the particular user's configuration. You can find where it is on a particular system by executing:

```
Print SpecialDirPath("Packages", 0, 0, 0)
```

Important:You must choose a very distinctive name for your package because that is the only thing that prevents some other package from overwriting yours. All package names starting with "WM" are reserved for WaveMetrics.

A package name is limited to 31 characters and must be a legal name for a directory on disk.

There are two ways to store package preference data:

In a special-format binary file stored in your package directory.

As Igor waves and variables in an Igor experiment file stored in your package directory.

The special-format binary file approach is relatively simple to implement but is not suitable for storing very large amounts of data. In most cases it is not necessary to store very large amounts of data so this is the way to go.

The use of the Igor experiment file supports storing a large amount of preference data but creates a problem of synchronizing your preference data stored in memory and your preference data stored on disk. It also leads to a proliferation of preference data stored in various experiments. You should avoid using this technique if possible.

Saving Package Preferences in a Special-Format Binary File

This approach supports preference data consisting of a collection of numeric and string data. You define a structure encapsulating your package preference data. You use the **LoadPackagePreferences** operation (page V-346) to load your data from disk and the **SavePackagePreferences** operation (page V-542) to save it to disk.

The LoadPackagePreferences and SavePackagePreferences were added in Igor Pro 5.04B07 so if you use this technique, your package will require that version or later.

SavePackagePreferences stores data from your package's preferences data structure in memory. LoadPackagePreferences returns that data to you via the same structure.

SavePackagePreferences also creates a directory for your package preferences and stores your data in a file in that directory. Your package directory is located in the Packages directory in Igor's preferences directory. The job of storing the preferences data in the file is handled transparently which, by default, automatically flushes your data to the file when the current experiment is saved or closed and when Igor quits.

You would call LoadPackagePreferences every time you need to access your package preference data and SavePackagePreferences every time you want to change your package preference data. You pass to these operations an instance of a structure that you define.

Here are example functions from the Package Preferences Demo experiment that use the LoadPackagePreferences and SavePackagePreferences operations to implement preferences for a particular package:

```
// NOTE: The package name you choose must be distinctive!
static StrConstant kPackageName = "Acme Data Acquisition"
static StrConstant kPrefsFileName = "PanelPreferences.bin"
static Constant kPrefsVersion = 100
static Constant kPrefsRecordID = 0

Structure AcmeDataAcqPrefs
   uint32version    // Preferences structure version number. 100 means 1.00.
   double panelCoords[4]      // left, top, right, bottom
   uchar phaseLock
   uchar triggerMode
   double ampGain
   uint32 reserved[100]       // Reserved for future use
EndStructure

// DefaultPackagePrefsStruct(prefs)
// Sets prefs structure to default values.
static Function DefaultPackagePrefsStruct(prefs)
   STRUCT AcmeDataAcqPrefs &prefs

   prefs.version = kPrefsVersion

   prefs.panelCoords[0] = 5          // Left
   prefs.panelCoords[1] = 40         // Top
   prefs.panelCoords[2] = 5+190      // Right
   prefs.panelCoords[3] = 40+125     // Bottom
   prefs.phaseLock = 1
   prefs.triggerMode = 1
   prefs.ampGain = 1.0

   Variable i
   for(i=0; i<100; i+=1)
      prefs.reserved[i] = 0
   endfor
End

// SyncPackagePrefsStruct(prefs)
// Syncs package prefs structures to match state of panel.
// Call this only if the panel exists.
static Function SyncPackagePrefsStruct(prefs)
   STRUCT AcmeDataAcqPrefs &prefs

   // Panel does exists. Set prefs to match panel settings.
   prefs.version = kPrefsVersion

   GetWindow AcmeDataAcqPanel wsize
   // NewPanel uses device coordinates. We therefore need to scale from
   // points (returned by GetWindow) to device units for windows created
   // by NewPanel.
   Variable scale = ScreenResolution / 72
   prefs.panelCoords[0] = V_left * scale
   prefs.panelCoords[1] = V_top * scale
   prefs.panelCoords[2] = V_right * scale
   prefs.panelCoords[3] = V_bottom * scale

   ControlInfo /W=AcmeDataAcqPanel PhaseLock
   prefs.phaseLock = V_Value         // 0=unchecked; 1=checked

   ControlInfo /W=AcmeDataAcqPanel TriggerMode
   prefs.triggerMode = V_Value       // Menu item number starting from on

   ControlInfo /W=AcmeDataAcqPanel AmpGain
   prefs.ampGain = str2num(S_value)  // 1, 2, 5 or 10
End

// InitPackagePrefsStruct(prefs)
// Sets prefs structures to match state of panel or
// to default values if panel does not exist.
static Function InitPackagePrefsStruct(prefs)
   STRUCT AcmeDataAcqPrefs &prefs

   DoWindow AcmeDataAcqPanel
```

```
   if (V_flag == 0)
      // Panel does not exist. Set prefs struct to default.
      DefaultPackagePrefsStruct(prefs)
   else
      // Panel does exists. Sync prefs struct to match panel state.
      SyncPackagePrefsStruct(prefs)
   endif
End

static Function LoadPackagePrefs(prefs)
   STRUCT AcmeDataAcqPrefs &prefs

   // This loads preferences from disk if they exist on disk.
   LoadPackagePreferences kPackageName, kPrefsFileName, kPrefsRecordID, prefs

   // If error or prefs not found or not valid, initialize them.
   if (V_flag!=0 || V_bytesRead==0 || prefs.version!=kPrefsVersion)
      InitPackagePrefsStruct(prefs) // Set from panel if it exists or to default values.
      SavePackagePrefs(prefs)       // Create initial prefs record.
   endif
End

static Function SavePackagePrefs(prefs)
   STRUCT AcmeDataAcqPrefs &prefs

   SavePackagePreferences kPackageName, kPrefsFileName, kPrefsRecordID, prefs
End
```

The package preferences structure, AcmeDataAcqPrefs in this case, must not use fields of type Variable, String, WAVE, NVAR, SVAR or FUNCREF because these fields refer to data that may not exist when LoadPackagePreferences is called. It can use fields of type char, uchar, int16, uint16, int32, uint32, float and double as well as fixed-size arrays of these types and substructures with fields of these types.

Use the reserved field to add fields to the structure in a backward-compatible fashion. For example, a subsequent version of the structure might look like this:

```
Structure AcmeDataAcqPrefs
   uint32   // Preferences structure version number. 100 means 1.00.
   double panelCoords[4]      // left, top, right, bottom
   uchar phaseLock
   uchar triggerMode
   double ampGain
   uint32 triggerDelay
   uint32 reserved[99]        // Reserved for future use
EndStructure
```

Here the triggerDelay field was added and size of the reserved field was reduced to keep the overall size of the structure the same. The AcmeDataAcqLoadPackagePrefs function would also need to be changed to set the default value of the triggerDelay field.

If you need to change the structure such that its size changes or its fields are changed in an incompatible manner then you must change your structure version, which will overwrite old preferences with new preferences.

A functioning example using this technique can be found in:

"Igor Pro Folder:Examples:Programming:Package Preferences Demo.pxp"

In the example above we store just one structure in the preference file. However LoadPackagePreferences and SavePackagePreferences allow storing any number of structures of the same or different types in the preference file. You can store either multiple instances of the same structure or multiple different structures. You must assign a unique nonnegative integer as a record ID for each structure stored and pass this record ID to LoadPackagePreferences and SavePackagePreferences. You could use this feature, for example, to store a different structure for each type of control panel that your package presents. Since all data is cached in memory you should not attempt to store hundreds or thousands of structures.

In almost all cases a particular package will need just one preference file. For the rare cases where this is inconvenient, LoadPackagePreferences and SavePackagePreferences allow each package to create any

number of preference files, each with a distinct file name. All of the preference files for a particular package are stored in the same directory, the package's preferences directory. Each file can store a different set of structure. However, the code that implements this feature is not tuned to handle large numbers of files so you should not use this feature indiscriminately.

Saving Package Preferences in an Experiment File

This approach supports package preference data consisting of waves, numeric variables and string variables. It is more difficult to implement than the special-format binary file approach and is not recommended except for expert programmers and then only if the previously described approach is not suitable.

You use the SaveData operation to store your waves and variables in a packed experiment file in your package directory on disk. You can later use the LoadData operation to load the waves and variables into a new experiment.

You must create your package directory as illustrated by the SavePackagePrefs function below.

The following example functions save and load package preferences. These functions assume that the package preferences consist of all waves and variables at the top level of the package's data folder. You may need to customize these functions for your situation.

```
// SavePackagePrefs(packageName)
// Saves the top-level waves, numeric variables and string variables
// from the data folder for the named package into a file in the Igor
// preferences hierarchy on disk.
Function SavePackagePrefs(packageName)
    String packageName              // NOTE: Use a distinctive package name.

    // Get path to Packages preferences directory on disk.
    String fullPath = SpecialDirPath("Packages", 0, 0, 0)
    fullPath += packageName

    // Create a directory in the Packages directory for this package
    NewPath/O/C/Q tempPackagePrefsPath, fullPath

    fullPath += ":Preferences.pxp"

    String saveDF = GetDataFolder(1)
    SetDataFolder root:Packages:$packageName
    SaveData/O/Q fullPath           // Save the preference file
    SetDataFolder saveDF

    // Kill symbolic path but leave directory on disk.
    KillPath/Z tempPackagePrefsPath
End

// LoadPackagePrefs(packageName)
// Loads the data from the previously-saved package preference file,
// if it exist, into the package's data folder.
// Returns 0 if the preference file existed, -1 if it did not exist.
// In either case, this function creates the package's data folder if it
// does not already exist.
// LoadPackagePrefs does not affect any other data already in the
// package's data folder.
Function LoadPackagePrefs(packageName)
    String packageName              // NOTE: Use a distinctive package name.

    Variable result = -1
    String saveDF = GetDataFolder(1)

    NewDataFolder/O/S root:Packages     // Ensure root:Packages exists
    NewDataFolder/O/S $packageName      // Ensure package data folder exists

    // Find the disk directory in the Packages directory for this package
    String fullPath = SpecialDirPath("Packages", 0, 0, 0)
    fullPath += packageName
    GetFileFolderInfo/Q/Z fullPath
    if (V_Flag == 0)                    // Disk directory exists?
        fullPath += ":Preferences.pxp"
        GetFileFolderInfo/Q/Z fullPath
        if (V_Flag == 0)                // Preference file exist?
            LoadData/O/R/Q fullPath     // Load the preference file.
            result = 0
```

```
      endif
   endif

   SetDataFolder saveDF
   return result
End
```

The hard part of using the experiment file for saving package preferences is not in saving or loading the package preference data but in choosing when to save and load it so that the latest preferences are always used. There is no ideal solution to this problem but here is one strategy:

1. When package preference data is needed (e.g., you are about to create your control panel and need to know the preferred coordinates), check if it exists in memory. If not load it from disk.
2. When the user does a New Experiment or quits Igor, if package preference data exists in memory, save it to disk. This requires that you create an IgorNewExperimentHook function and an IgorQuitHook function.
3. When the user opens an experiment file, if it contains package preference data, delete it and reload from disk. This requires that you create an AfterFileOpenHook function. This is necessary because the package preference data in the just opened experiment is likely to be older than the data in the package preference file.

Creating Formatted Text

The printf, sprintf, and fprintf operations print formatted text to Igor's history area, to a string variable or to a file respectively. The wfprintf operation prints formatted text based on data in waves to a file.

All of these operations are based on the C printf function which prints the contents of a variable number of string and numeric variables based on the contents of a format string. The format string can contain literal text and conversion specifications. Conversion specifications define how a variable is to be printed.

Here is a simple example:

```
printf "The minimum is %g and the maximum is %g\r", V_min, V_max
```

In this example, the format string is `"The minimum is %g and the maximum is %g\r"` which contains some literal text along with two conversion specifications — both of which are "`%g`" — and an escape code ("`\r`") indicating "carriage-return". If we assume that the Igor variable V_min = .123 and V_max = .567, this would print the following to Igor's history area:

```
The minimum is .123 and the maximum is .567
```

We could print this output to an Igor string variable or to a file instead of to the history using the **sprintf** (see page V-590) or **fprintf** (see page V-183) operations.

Printf Operation

The syntax of the printf operation is:

```
printf format [, parameter [, parameter ]. . .]
```

where *format* is the format string containing literal text or format specifications. The number and type of parameters depends on the number and type of format specifications in the format string. The parameters, if any, can be literal numbers, numeric variables, numeric expressions, literal strings, string variables or string expressions.

The conversion specifications are very flexible and make printf a powerful tool. They can also be quite involved. The simplest specifications are:

Specification	What It Does
%g	Converts a number to text using integer, floating point or exponential notation depending on the number's magnitude.
%e	Converts a number to text using exponential notation.
%f	Converts a number to text using floating point notation.

Specification	What It Does
%d	Converts a number to text using integer notation.
%s	Converts a string to text.

Here are some examples:

```
printf "%g, %g, %g\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3.14159, 6.022e+23, 1.602e-19
```

```
printf "%e, %e, %e\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3.141593e+00, 6.022000e+23, 1.602000e-19
```

```
printf "%f, %f, %f\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3.141593, 602200000000000027200000.000000, 0.000000
```

```
printf "%d, %d, %d\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3, 2147483647, 0
```

```
printf "%s, %s\r", "Hello, world", "The time is " + Time()
```

prints:

```
Hello, world, The time is 11:43:40 AM
```

Note that the output for 6.022e23 when printed using the %d conversion specification is wrong. This is because 6.022e23 is too big a number to represent as an 32 bit integer.

If you want better control of the output format, you need to know more about conversion specifications. It gets quite involved. See the **printf** operation on page V-499.

sprintf Operation

The sprintf operation is very similar to printf except that it prints to a string variable instead of to Igor's history. The syntax of the sprintf operation is:

```
sprintf stringVariable, format [, parameter [, parameter ]. . .]
```

where *stringVariable* is the name of the string variable to print to and the remaining parameters are as for printf. sprintf is useful for generating text to use as prompts in macros, in axis labels and in annotations.

fprintf Operation

The fprintf operation is very similar to printf except that it prints to a file instead of to Igor's history. The syntax of the fprintf operation is:

```
fprintf variable, format [, parameter [, parameter ]. . .]
```

where *variable* is the name of a numeric variable containing the file reference number for the file to print to and the remaining parameters are as for printf. You get the file reference number using the Open operation, described under **Open and Close Operations** on page IV-172.

For debugging purposes, if you specify 1 for the file reference number, Igor prints to the history area instead of to a file, as if you used printf instead of fprintf.

wfprintf Operation

The wfprintf operation is very similar to printf except that it prints the contents of one to 100 waves to a file. The syntax of the wfprintf operation is:

```
wfprintf variable, format [/R=(start,end)] wavelist
```

variable is the name of a numeric variable containing the file reference number for the file to print to.

Example Using fprintf and wfprintf

Here is an example of a command sequence that creates some waves and put values into them and then writes them to an output file with column headers.

```
Make/N=25 wave1, wave2, wave3
wave1 = 100+x; wave2 = 200+x; wave3 = 300+x
Variable f1
Open f1
fprintf f1, "wave1, wave2, wave3\r"
wfprintf f1, "%g, %g, %g\r" wave1, wave2, wave3
Close f1
```

This generates a comma delimited file. To generate a tab delimited file, use:

```
fprintf f1, "wave1\twave2\twave3\r"
wfprintf f1, "%g\t%g\t%g\r" wave1, wave2, wave3
```

Since tab-delimited is the default format for wfprintf, this last command is equivalent to:

```
wfprintf f1, "" wave1, wave2, wave3
```

Client/Server Overview

Igor Pro can act as a server — accepting commands and data from a client program and returning results, as a client — sending commands and data to a server program, or as both at the same time.

For the Macintosh, see **Apple Events** on page IV-232 for server information and **AppleScript** on page IV-234 for client capabilities. Previous versions of Igor supported an Apple technology called Program-to-Program Communication (PPC). Apple's operating systems no longer support PPC so it is no longer supported in Igor.

For Windows, see **ActiveX Automation** on page IV-236. Igor can play the role of an Automation server but not an Automation client. However it is possible to generate script files that allow Igor to indirectly play the role of client.

On Windows, Igor also supports Dynamic Data Exchange (DDE) and can be a DDE server or DDE client. Because DDE is obsolescent and being phased out by Microsoft, new programming should use ActiveX automation. Igor's support for DDE is described in the Obsolete Topics help file.

Apple Events

This topic is of interest to *Macintosh* programmers. Windows users should see the section for **ActiveX Automation** on page IV-236.

This topic contains information for Igor users who wish to control Igor from other programs (e.g., AppleScript). It also contains information useful to people who are writing their own programs and wish to use Igor Pro as a compute/graphing engine.

There is also a mechanism that allows Igor to act like a controller and initiate Apple event communication with other programs. See **AppleScript** on page IV-234.

It is assumed that the reader of this material is an experienced Igor user.

Apple Event Capabilities

Igor Pro supports the following Apple events:

Event	Suite	Action
Open Application	Required	Basically a nop; don't use.
Open Document	Required	Loads an experiment.
Print Document	Required	NA; don't use.
Quit Application	Required	Quits.
Close	Core	Acts on experiment, window or PPC port.
Save	Core	Acts on experiment only.
Open	Core	NA; don't use.
Do Script	Misc	Executes commands; can return ASCII results.
Eval Expression	Misc	Same as Do Script; obsolete but included for compatibility.

Apple Events — Basic Scenario

You use the Open Document event to cause Igor to load an experiment with whatever goodies you find useful (macros, useful waves and variables or whatever). You then use the Do Script or Eval Expression events to send commands to Igor for execution and to retrieve results. To get data into Igor you write files and then send commands to Igor to load the data. To get data waves from Igor you do the reverse. To get PICT data you send commands to Igor that cause it to write a PICT file that you can read. You may then close the experiment and start over with a new one. You will not likely use the Save event.

Apple Events — Obtaining Results from Igor

To return information from Igor, you will need to embed special commands in the script you send to Igor for execution. When Igor encounters these commands, it appends results to a packet that is returned to your application after script execution ends. The special commands are variations on the standard Igor commands FBinWrite and fprintf. Both of these commands take a file reference number as a parameter. If the magic value zero is used rather than a real file reference number, then the data that would normally be written to a file is appended to the result packet.

As far as Igor is concerned, there is no difference between the Do Script and Eval Expression events. However, old applications may expect results from Eval Expression and not from Do Script.

To use waves and PICTs with Apple events, you will need to write or read the data via standard Igor files. For example, you might include

```
SavePICT/P=myPath as "a PICT file"
```

in a script that you send to Igor for execution. You could then read the file in your application.

Apple Event Details

This information is intended for programmers familiar with Apple events terminology.

Some of the following events can act on experiments or windows.

To specify an experiment, use object class cDocument (`'docu'`) and specify either formAbsolutePosition with index=1 or formName with name=*name of experiment*.

To specify a window, use object class cWindow (`'cwin'`) and either formAbsolutePosition or formName with name=*title of window*.

Event	Class	Code	Action
Open Application	`'aevt'`	`'oapp'`	Basically a nop; don't use.
Open Document	`'aevt'`	`'odoc'`	Loads an experiment. Direct object is assumed to be coercible to a File System Spec record.
Print Document	`'aevt'`	`'pdoc'`	NA; don't use.
Quit Application	`'aevt'`	`'quit'`	Quits the program. If the experiment was modified, then Igor attempts to interact with the user to get save/no save directions. If interaction is not allowed, then an error is returned and nothing is done. To prevent errors, send the close event with appropriate save options prior to sending quit.
Close	`'core'`	`'clos'`	Acts on an experiment or window. For a window, the save/no save/ask optional parameter (keyAESaveOptions) is allowed and refers to making/replacing a recreation macro. For a document (experiment), keyAESaveOptions is allowed and an additional optional parameter keyAEDestination my be used to specify where to save (must be coercible to a FSS). If this is not given and the experiment is untitled and if an attempt to interact with the user fails then the experiment is not saved and an error (such as errAENoUserInteraction) is returned. Note that if the optional destination is given then the save options are ignored (why give a destination and then say no save?).
Save	`'core'`	`'save'`	Acts on experiment only. Takes same optional destination parameters as Close. A save with a destination is the same as a Save as.
Do Script	`'misc'`	`'dosc'`	Same as Eval Expression.
Eval Expression	`'aevt'`	`'eval'`	Executes commands. Acts just as if commands had been typed into the command line except the individual command lines are preceded by a "¶" symbol rather than the usual "•" symbol. Also, errors are returned in the error reply parameter of the event rather than putting up a dialog. **Note**: You can suppress history logging by executing the command, "Silent 2", and you can turn it back on by executing "Silent 3". Direct parameter must be text and not a file. Text can be of any length. You can return a string containing results by using the fprintf command with a file reference number of zero.

AppleScript

This topic is of interest to *Macintosh* programmers. Windows users should see the section for **ActiveX Automation** on page IV-236.

Igor supports the creation and execution of simple AppleScripts in order to send commands to other programs.

To execute an AppleScript program, you first compose it in a string and then pass it to the ExecuteScriptText operation, which in turn passes the text to Apple's scripting module for compilation and execution. The result (which might be an error message) is placed in a string variable named S_value. Igor does not save the compiled script so every time you call ExecuteScriptText your script will have to be recompiled. See the **ExecuteScriptText** operation on page V-145 for additional details.

The documentation for the **ExecuteScriptText** operation (page V-145) includes an example that shows how to execute a Unix command.

Because there is no easy way to edit a script or to see where errors occur, you should first test your script using Apple's Script Editor application.

You can use "Silent 2" to prevent commands your script sends to Igor from being placed in the history area.

You can send commands to Igor without using the tell keyword.

You should check your quoting carefully. Your text must be quoted both for Igor and for Apple's scripting system. For example,

```
ExecuteScriptText "Do Script \"Print \\\"hello\\\"\""
```

You should compose scripts in string variables one line at a time to improve readability.

If an error occurs that you can't figure out, print the string, copy from the history and paste into a Script Editor for debugging.

If the script returns a text return value, it will be quoted within the S_value string.

Don't forget to include the carriage return escape code, \r, at the end of each line of a multiline script.

The first time you call this routine, it may take an extra long time while the Mac OS loads the scripting modules.

Executing Unix Commands on Mac OS X

On Mac OS X, you can use AppleScript to send a command to the Unix shell. Here is a function that illustrates this:

```
Function/S ExecuteUnixShellCommand(uCommand, printCommandInHistory,
printResultInHistory)
    String uCommand                    // Unix command to execute
    Variable printCommandInHistory
    Variable printResultInHistory

    if (printCommandInHistory)
        printf "Unix command: %s\r", uCommand
    endif

    String cmd
    sprintf cmd, "do shell script \"%s\"", uCommand
    ExecuteScriptText cmd

    if (printResultInHistory)
        Print S_value
    endif

    return S_value
End
```

You can test the function with this command:

```
ExecuteUnixShellCommand("ls", 1, 1)
```

Life is a bit more complicated if the command that you want to execute contains spaces or other nonstandard Unix command characters. For example, imagine that you want to execute this:

```
ls /System/Library/Image Capture
```

These commands will not work because of the space in the command:

```
String unixCmd = "ls /System/Library/Image Capture"
ExecuteUnixShellCommand(unixCmd, 1, 1)
```

You need to quote the entire Unix command. In order to do this such that the quotes will make it through Igor's parser and AppleScript's parser, you must do this:

```
String unixCmd = "ls \\\"/System/Library/Image Capture\\\""
ExecuteUnixShellCommand(unixCmd, 1, 1)
```

Igor's parser converts \\ to \ and \" to ", so AppleScript sees this:

```
"ls \"/System/Library/Image Capture\""
```

AppleScript's parser converts \" to " so Unix sees this:

```
ls "/System/Library/Image Capture"
```

On Macintosh, if your system is set to use Japanese as the preferred language, this technique of embedding backslashes will not work. This is because, in the Japanese script, the code for backslash is used for the yen symbol. AppleScript receives yen symbols where backslash is intended and returns an error. A possible workaround is to put your commands in a Unicode file, created in TextEdit for example, and then use ExecuteUnixShellCommand to run execute the commands in Unicode file.

ActiveX Automation

ActiveX Automation, often called just Automation, is Microsoft's technology for allowing one program to control another. The program that does the controlling is called the Automation client. The program that is controlled is called the Automation Server. The client initiates things by making calls to the server which carries out the requested actions and returns results.

Automation client programs are most often written in Visual Basic or C++. They can also be written in other programming languages and in various scripting languages such as VBScript, JavaScript, Perl, Python and so on.

As of Igor Pro 5, Igor can play the role of Automation Server. If you want to write an client program to drive Igor, see "Automation Server Overview" in the "Automation Server" help file in "\Igor Pro Folder\Miscellaneous\Windows Automation".

Igor Pro does not directly support playing the role of Automation client. However, it is possible to write an Igor program which generates a script file which can act like an Automation client. See the CallMicrosoftWord experiment in the Igor Pro Folder:Examples:Programming folder.

An intermediate-level C++ programmer can also write an Igor XOP which plays the role of Automation client.

Igor Command Line

This information is for Windows programmers only. You can call Igor Pro from a Windows batch file or even from Igor itself using ExecuteScriptText using this operation-like syntax:

Igor.exe

Igor.exe [**/I /N /Automation**][***pathToFileOrCommands***][***pathToFile***]…
Igor.exe [**/I /Q /X /Automation**] "***commands***"
Igor.exe /SN=num /KEY="*key*" /NAME="*name*" [/ORG="*org*" /QUIT]

Parameters

The usual parameter to Igor.exe is a file which Igor opens. It is recommended that both the path to Igor.exe and the path to the file parameter be enclosed in quotes:

```
"C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe" "C:\Igor Files\exp.pxp"
```

Multiple files can be opened by appending the path to the file(s) with an intervening space:

```
"C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe" "C:\Dir\exp.pxp"
"C:\Dir\exp.dat"
```

With the /X flag, only one parameter is allowed and is interpreted as Igor commands:

```
"C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe" /X "Make/O data=x;Display data"
```

The /SN, /KEY, and/NAME flags must all be used to successfully register Igor Pro. The optional /ORG parameter defaults to "".

Flags

Note: The / symbol can be replaced with a - symbol (ActiveX Automation uses a -Automation parameter when calling Igor Pro).

/Automation — Used automatically (along with /I) by the operating system when launching Igor Pro as an Automation Server. The command parameter that the OS sends is defined in the Registry, put there by the Igor installer or by the user, by merging an IgorProCOM.reg file. This flag isn't intended for use in batch files or ExecuteScriptText. For more details on ActiveX Automation Server, see "Automation Server Overview" in the "Automation Server" help file.

It can, however be used from the command line or a batch file to communicate with other programs in combination with /X. The /Automation flag keeps Igor windows hidden, which may be useful when calling Igor Pro from a web server CGI program.

/I — Launches a new "instance" of Igor that will open the file or execute the commands. Pressing Ctrl while launching Igor is the same as using the /I flag.

Without /I, files are opened and commands are executed by any Igor.exe that is currently running. If a parameter is an experiment file, the currently open experiment is closed before opening the new one (see the /Y and /N flags).

/KEY="*key*" — Specifies the license activation key. Use a value of the form:

```
/KEY="ABCD-EFGH-IJKL-MNOP-QR"
```

Do not omit the quotes, or it will fail.

/N — Forces the current experiment to be closed without saving if any of the file parameters are an experiment file.

To save a currently open experiment, use:

```
Igor.exe /X "SaveExperiment"
```

/NAME="*name*" — Defines the name of the licensed user(s). Cannot be "".

/ORG="*org*" — Specifies the optional name of the licensed organization. Default is "". Because Windows interprets the & symbol to mean "underline the next character when displayed in a dialog window," use && to display one & character in the About Igor dialog.

/Q — Doesn't show

```
Command line: /X "Make/O data=s;Display data"
```

in Igor's history window when using /X or /SN, etc.

/QUIT — Quits Igor Pro after entering license information when used with /SN, /KEY, and /NAME. Otherwise /QUIT is ignored.

To quit Igor Pro, use:

```
Igor.exe /X "Quit/N"
```

/SN=*num* — Specifies the license serial number.

/X — Executes the commands in the first (and only allowed) parameter. Use semicolons to separate commands.

Details

As of Igor 6.2, if a copy of Igor.exe is already running and if Igor.exe is launched again without /X, /SN or any path to a file, a new instance of Igor.exe is started.

Previous to Igor 6.2, launching Igor under those conditions would only activate the already-running instance of Igor.exe.

This means that double-clicking the Igor.exe icon will start another instance of Igor.exe, but double-clicking an experiment file will still open that file in the frontmost instance of Igor (or start up Igor if it isn't running), as it always has.

Example

This function launches another instance of Igor to open an experiment file:

```
Function LaunchAnotherIgor(expPath)
   String expPath       // Full Windows path to experiment file
                        // e.g.,  "C:\\Igor Files\\Experiment.pxp"

   String quote = "\""  // String containing a double-quote

   // Get path to Igor Pro folder in Macintosh file format.
   PathInfo Igor        // Stores output in S_path.

   // Get path to Igor in Windows format.
   String igorPath= ParseFilePath(5, S_path, "\\", 0, 0) + "Igor.exe"

   String scriptText = quote + igorPath + quote + " /I " + quote + expPath + quote
   ExecuteScriptText scriptText
End
```

These batch file commands register Igor Pro with the given (fictional) serial number and license activation key:

```
Igor.exe /SN=1234567/KEY="ABCD-EFGH-IJKL-MNOP-QR"/NAME="Me" /ORG="You && Me, Inc." /QUIT
```

Igor as a WWW CGI-Bin Server

You can use Igor Pro as part of a Web server on both Macintosh and Windows. For example, you might create a form that allows users to enter parameters and then see an Igor created graph based on the user's inputs.

On the Macintosh your Web server executes a compiled AppleScript (that you write based on our example) that communicates with Igor using the DoScript Apple event.

On Windows, we supply an IgorCGI.exe executable program than communicates with Igor using DDE.

On Windows, we supply an IgorCGI.exe executable program that communicates with Igor Pro using DDE. Another option is to communicate directly using ActiveX Automation Server (see "Automation Server Overview" in the "Automation Server" help file) or on the Igor command line.

On both platforms, we provide example procedures that you keep in the Igor Procedures folder to help you decode the values users enter in the form with their Web browser.

For more information and sample code, see Technical Note PTN004 — "Igor CGI on Macintosh" and Technical Note PTN005 — "Igor CGI on Windows".

Network Communications

The following sections contain material related to the network communication and Internet-related capabilities of Igor Pro:

URLs

URLs, or Uniform Resource Locators, are compact strings that represent a resource available via the Internet. The description of the URL standard is described in RFC1738 (http://www.rfc-editor.org/rfc/rfc1738.txt) and updated in RFC3986 (http://www.rfc-editor.org/rfc/rfc3986.txt).

Each URL is composed of several different parts, most of which are optional:

```
<scheme>://<username>:<password>@<host>:<port>/<path>?<query>
```

Some examples of valid URLs are:

```
http://www.example.com
http://www.example.com/afolder?key1=45&key2=66
http://myusername:Passw0rD@www.example.com:8010/index.html
ftp://ftp.wavemetrics.com
file://C:\Data:Trial1:control.ibw
file://hd:Test:TestFile1.txt
```

For most operations and functions that take a *urlStr* parameter, only the scheme and host parts of the URL are required. See the **Supported Network Schemes** section for information on which schemes are supported by which operations and functions, and which port is used by default if it is not provided as part of the URL.

Usernames and Passwords

You can provide a username and password as part of the URL. However authentication credentials may not be supported by all schemes (such as file://). Some operations allow you to provide a username and password by using a flag, such as the /U and /W flags with **FTPDownload**.

If a URL contains a username and password in the URL and the authentication flags are also used, the values specified in the flags override values provided in the URL.

If you do not provide a username and password as part of the URL, and you do not use the authentication flags, then no authentication is attempted. An exception to this rule is that the FTP operations will login to the FTP server using "anonymous" as the username and a generic email address as the password.

If either the username or password contains special or reserved characters, those characters must be percent-encoded.

Supported Network Schemes

Different operations and functions support different schemes:

Operation	Supported Schemes	Default Port
FetchURL	http	80
	ftp	21
	file	Not applicable
FTP operations*	ftp	21

* Includes **FTPUpload**, **FTPDownload**, **FTPDelete**, and **FTPCreateDirectory**.

Percent Encoding

Percent encoding is a way to encode characters in URLs that would otherwise have a special meaning or could be misinterpreted by servers. For example, a space character in a URL is encoded as "%20" using a percent character followed by the hex code for a space in the ASCII character set.

Most URLs contain only the letters A-Z and a-z, the digits 0-9, and a few other characters such as the underscore (_), hyphen (-), period (.), and tilde (~).

A URL may also contain "reserved characters" that may have special meaning depending on the way that they are used. Every URL contains the reserved characters ":" and "/" and may also contain one or more of the following reserved characters: !*'();@&=+$,?#[].

All operations and functions provided by Igor Pro that accept a URL string parameter expect that the URL has already been percent-encoded as necessary.

In most cases you don't need to worry about percent encoding because most URLs don't use reserved characters except for their special meaning. If you need to use a reserved character in a way that differs from the character's special meaning, you must percent-encode the character. You can use the **URLEncode** function for this purpose.

It is important that you not pass your entire URL to URLEncode to be encoded because that URL will not be understood by a server. URLEncode percent-encodes all reserved characters in the string you pass to it, because it cannot distinguish between reserved characters used for their special meaning and reserved characters used outside of their special meaning. Instead, you must pass each piece of the URL through URLEncode so that the final URL uses the correct syntax.

As an example, we'll use URLEncode to properly encode a URL that contains the following parts:

Part Name	Example
Scheme	http
Username	A. MacGyver
Password	yj@!2M
Host	www.example.com
Path	/tape/duct
Query	discount=10%&color=red

Without any percent-encoding, the URL is:

```
http://A. MacGyver:yj@!2M@www.example.com/tape/duct?discount=10%&color=red
```

If this URL were passed to **FetchURL**, the result would be an error because the URL contains several reserved characters that are not intended to be used in their standard way. For example, the "@" character indicates the separation between the username:password information and the start of the host name, but in this case the password itself also contains the "@" character. In addition, the "%" character is typically used to indicate that the next two characters represent a percent-encoded character, but in this example it is also part of the query. Finally, the username contains a space character. The space character is not technically a reserved character, but should be percent-encoded to ensure that it is handled correctly.

The following table shows the values of the parts of the URL that need to be percent-encoded by passing them through the URLEncode function:

Part Name	Encoded Value
Username	A%2E%20MacGyver
Password	yj%40%212M
Host	www.example.com
Path	/tape/duct
Query	discount=10%25&color=red

The properly percent-encoded URL is:

```
http://A%2E%20MacGyver:yj%40%212M@www.example.com/tape/duct?discount=10%25&color=red
```

For keyword-value pairs that make up the query part, each keyword and value must be percent-encoded separately because the "=" character that separates the key from the value and the "&" character that separates the pairs in the list must not be percent-encoded.

For more information on percent-encoding and reserved characters, see http://en.wikipedia.org/wiki/Percent-encoding.

Safe Handling of Passwords

Some operations and functions support the use of a username and password when making a network connection. If you use sensitive passwords you must take certain precautions to prevent them from being accidentally revealed.

1. Always use the /V=0 flag when using a username or password with the /U (username) and /W (password) flags. Otherwise, the debugging information that is, by default, printed to the command history window will contain those values and anyone who sees the experiment could see them.
2. Do not hard code username or password values into procedures, since anyone with access to the procedure file could read them.
3. Do not store username or password values in global variables. Since global variables are saved with an experiment, if someone else had access to your experiment they could see this information.

Here is an example of how a username and sensitive password can be used in a secure manner:

```
Function SafeLogin()
   String username = ""
   String password = ""
   Prompt username, "Username"
   Prompt password, "Password"
   DoPrompt "Enter username and password", username, password
   if (V_flag == 1)
      // User hit cancel button, so do nothing.
      return 0
   endif

   // Percent-encode in case username and password contain reserved characters.
   String encodedUser = URLEncode(username)
   String encodedPass = URLEncode(password)

   String theURL
   sprintf theURL, "http://%s:%s@www.example.com", encodedUser, encodedPass
   String response = FetchURL(theURL)
   // NOTE: For FTP operations, make sure to use /V=0 so that the username
   // and password are not printed to the history.

   return 0
End
```

Note that the user is prompted to provide the username and password when the function is called and that only local string variables are used to store the username and password. The values in those string variables are not stored once the function is done executing.

Note also that the password is not hidden during entry in the dialog. Igor currently does not provide a way to do this.

Network Timeouts and Aborts

Some network calls may return an error code to Igor if they timeout. Depending on the specific operation or function, there can be a number of causes for a timeout.

If a network connection cannot be made after a period of time it will timeout. The amount of time allowed for a connection to be established is dependent on several factors.

You can always abort a network operation or function by pressing cmd-period (Macintosh) or Ctrl-Break (Windows). You must hold the keys down until Igor aborts the operation.

Network Connections From Multiple Threads

All network-related operations and functions are thread-safe, which means that they can be called from multiple preemptive threads at the same time. This capability can be useful when:

- You want to retrieve information from several different URLs as quickly as possible.
- You want to do a long download or other operation in the background to avoid tieing Igor up.

The following example illustrates the first of these cases. It uses **FetchURL** to retrieve a list of the most frequently downloaded books from the Project Gutenberg web site. It then uses FetchURL to download the entire text of the top four books and prints the number of characters in each.

```
ThreadSafe Function GetThePage(url)
   String url

   String response = FetchURL(url)
   return strlen(response)
End

Function GutenbergTopCharacterCount()
   String topBooksURL = "http://www.gutenberg.org/browse/scores/top"
   String baseURL = "http://www.gutenberg.org/files/"

   // Get the contents of the page.
   String response = FetchURL(topBooksURL)
   Variable error = GetRTError(1)
   if (error || numtype(strlen(response)) != 0)
      Print "Error getting the list of most popular books."
      return 0
   endif

   String topBooksHTML = response

   // Remove all line endings.
   topBooksHTML = ReplaceString("\n", topBooksHTML, "")
   topBooksHTML = ReplaceString("\r", topBooksHTML, "")

   // Parse the page to get the section of the page
   // with the list of the most popular books from yesterday.
   // This could break if the format of the web page changes.
   String regExp = "(?i)<h2 id=\"books-last1\">.*?<ol>(.*?)</ol>"
   String topYesterdayHTML = ""
   SplitString/E=regExp topBooksHTML, topYesterdayHTML
   if (V_flag != 1)
      Print "Error parsing the top 100 books section."
      return 0
   endif

   // Replace the line endings.
   topYesterdayHTML = ReplaceString("</li><li>", topYesterdayHTML, "\r")
```

```
   // Create a wave to store text info about the top four books.
   Variable numBooksToUse = 4
   Make/O/T/N=(numBooksToUse, 2) topBooksInfo

   Make/O/N=(numBooksToUse) characterCounts

   Variable n
   String bookNumStr
   Variable bookNum
   String titleAuthor
   String thisLine
   Variable pos
   String bookURL = ""
   regExp = "(?i)a href=\".*?(\d+)\">(.+?)</a>"
   for (n=0; n<numBooksToUse; n+=1)
      // For each book we're going to look at, get the
      // partial URL and the title/author text.
      thisLine = StringFromList(n, topYesterdayHTML, "\r")
      SplitString/E=regExp thisLine, bookNumStr, titleAuthor
      if (V_flag != 2)
         Print "Error parsing the URL and title/author information."
         return 0
      endif

      // Remove the (###) stuff at the end of titleAuthor if it's there.
      pos = strsearch(titleAuthor, "(", 0)
      if (pos > 0)
         titleAuthor = titleAuthor[0, pos - 1]
      endif

      bookNum = str2num(bookNumStr)

      // Store the information about the book in the text wave.
      sprintf bookURL, "%s%d/%d.txt", baseURL, bookNum, bookNum
      topBooksInfo[n][0] = bookURL
      topBooksInfo[n][1] = titleAuthor
   endfor

   // Download each book (using multiple threads if possible)
   // and count the number of characters in each.
   MultiThread characterCounts = GetThePage(topBooksInfo[p][0])

   // Print the results.
   Print "The top four books by download from yesterday are:"
   for (n=0; n<numBooksToUse; n+=1)
      Printf "%s (%d characters)\r", topBooksInfo[n][1], characterCounts[n]
   endfor
End
```

Here is an example of what the output was when this help file was written:

The top four books by download from yesterday are:

```
  Ulysses by James Joyce (1573044 characters)
  Alice's Adventures in Wonderland by Lewis Carroll (167529 characters)
  Piper in the Woods by Philip K. Dick (62214 characters)
  Pride and Prejudice by Jane Austen (704160 characters)
```

File Transfer Protocol (FTP)

The **FTPDownload**, **FTPUpload**, **FTPDelete**, and **FTPCreateDirectory** operations support simple transfers of files and directories over the Internet.

Since Igor's SaveNotebook operation can generate HTML files from notebooks, it is possible to write an Igor procedure that downloads data, analyzes it, graphs it, and uploads an HTML file to a directory used by a Web server. You can then use the BrowseURL operation to verify that everything worked as expected. For a demo of some of these features, see "Igor Pro Folder:Examples:Feature Demos:Web Page Demo.pxp".

FTP Limitations

All FTP operations run "synchronously". This means that, if the operation executes in the main thread, Igor can not do anything else. However, it is possible to perform these operations using an Igor preemptive thread so that they execute in the background and you can continue to use Igor for other purposes. For more information, see **Network Connections From Multiple Threads** on page IV-242.

Igor does not currently provide any way for the user to browse the remote server from within Igor itself.

Igor does not provide any secure way to store passwords. Consequently, you should not use Igor for FTP in situations where tight security is required. See **Safe Handling of Passwords** on page IV-241 for an example of how to securely prompt the user for a password.

Igor does not provide any support for using proxy servers. Proxy servers are security devices that stand between the user and the Internet and permit some traffic while prohibiting other traffic. If your site uses a proxy server, FTP operations may fail. Your network administrator may be able to provide a solution.

Igor does not include operations for listing a server directory or changing its current directory.

Downloading a File

The following commands transfer a file from an FTP server to a local hard disk:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test:TestFile1.txt"          // Macintosh
FTPDownload/U="ftpTestAccount"/W="dropbox" url, localPath
```

These commands transfer the file TestFile1.txt from the WaveMetrics FTP server into the Test directory on the local hard disk "hd". The Test directory must already exist on the local hard disk. The TestFile1.txt file may or may not exist on the local hard disk. If it does not exist, the FTPDownload command will create it. If it does exist, FTPDownload will ask if you want to overwrite it. To overwrite it without being asked, use the /O flag.

Warning: If you elect to overwrite it, all previous contents of the local TestFile1.txt file will be obliterated.

As of this writing, "ftpTestAccount" is the user name and "dropbox" is the password for the "test" directory on the WaveMetrics FTP server.

Now consider these commands:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test:FileA.txt"
FTPDownload/U="ftpTestAccount"/W="dropbox" url, localPath
```

This does the same thing as the previous example except that the resulting file on the local hard disk will be named FileA.txt instead of TestFile1.txt.

FTPDownload presents a dialog asking you to specify the local file name and location in the following cases:

1. You use the /I (interactive) flag.
2. The parent directory specified by the local path does not exist. In the examples above, the parent directory is Test.
3. The specified local file exists and you have not used the /O (overwrite) flag.

Downloading a Directory

The following commands transfer a directory from an FTP server to a local hard disk:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test:TestDir1"
FTPDownload/D/U="ftpTestAccount"/W="dropbox" url, localPath
```

Note the use of the /D flag to specify that you are transferring a directory.

This command transfers the TestDir1 directory from the WaveMetrics FTP server into the Test directory on the local hard disk "hd". The Test directory must already exist on the local hard disk. The TestDir1 directory may or may not exist. If it does not exist, the FTPDownload command will create it. If it does exist, FTPDownload will ask if you want to overwrite it. To overwrite it without being asked, use the /O flag.

Warning: If you elect to overwrite it, all previous contents of the local TestDir1 will be obliterated.

Now consider these commands:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test:TestDir2"
FTPDownload/D/U="ftpTestAccount"/W="dropbox" url, localPath
```

This does the same thing as the previous example except that the resulting directory on the local hard disk will be named TestDir2 instead of TestDir1.

Warning: If you elect to overwrite it, all previous contents of the local TestDir2 will be obliterated.

The local path that you specify must not end with a colon or backslash. For example, if you execute:

```
FTPDownload/D "ftp://ftp.wavemetrics.com/pub/test/TestDir1", "hd:Test:TestDir1:"
```

FTPDownload will present a dialog asking you to specify the local directory because the local path ends with a colon and FTPDownload is looking for the name of the directory to be created on the local hard disk.

FTPDownload presents a dialog asking you to specify the local directory in the following cases:

1. You use the /I (interactive) flag.
2. The parent directory specified by the local path does not exist. In the examples above, the parent directory is Test.
3. The specified directory (TestDir1 in the example above) exists and you have not used the /O (overwrite) flag.
4. FTPDownload gets an error when it tries to create the specified directory. This could happen, for example, if the directory name that you specify is not a legal directory name. For example, the name might be too long or use characters that are forbidden in the local file system.

Uploading a File

The following commands upload a file to an FTP server:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test:TestFile1.txt"
FTPUpload/U="ftpTestAccount"/W="dropbox" url, localPath
```

These commands transfer the file TestFile1.txt from the local hard disk into the test directory on the WaveMetrics FTP server. The test directory is created if it does not already exist.

Note: The /O flag has no effect on the FTPUpload operation when uploading a file. FTPUpload *always* overwrites an existing server file, whether /O is used or not.

Warning: If you overwrite a server file, all previous contents of the file are obliterated.

To overwrite an existing file on the server, you must have permission to delete files on that server. The server administrator determines what permission a particular user has.

Now consider these commands:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile2.txt"
String localPath = "hd:Test:TestFile1.txt"
FTPUpload/U="ftpTestAccount"/W="dropbox" url, localPath
```

This does the same thing as the previous example except that the resulting file on the FTP server will be named TestFile2.txt instead of TestFile1.txt.

FTPUpload presents a dialog asking you to specify the local file in the following cases:

1. You use the /I (interactive) flag.
2. The local parent directory (e.g., Test) or the local file (e.g., TestFile1.txt) does not exist.

Uploading a Directory

The following commands upload a directory to an FTP server:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test:TestDir1"
FTPUpload/D/U="ftpTestAccount"/W="dropbox" url, localPath
```

These commands transfer the TestDir1 directory from the local hard disk into the test directory on the WaveMetrics FTP server. The test and TestDir1 directories are created on the server if they do not already exist. If the TestDir1 directory does exist, FTPUpload overwrites it.

Note: FTPUpload *always* overwrites an existing server directory, whether /O is used or not.

Warning: If you overwrite a server directory using /O or /O=1, all previous contents of the directory will be obliterated.

If /O=2 is used, FTPUpload performs a merge of the directory contents. This means that files and directories in the source overwrite files and directories on the server that have the same name, but files and directories on the server whose names do not conflict with those in the source directory are not modified.

To overwrite an existing directory on the server, you must have permission to delete directories on that server. The server administrator determines what permission a particular user has.

Now consider these commands:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir2"
String localPath = "hd:Test:TestDir1"
FTPUpload/D/U="ftpTestAccount"/W="dropbox" url, localPath
```

This does the same thing as the previous example except that the resulting directory on the FTP server will be named TestDir2 instead of TestDir1.

The local path that you specify must not end with a colon or backslash. For example, if you execute:

```
FTPUpload/D "ftp://ftp.wavemetrics.com/pub/test/TestDir1", "hd:Test:TestDir1:"
```

FTPUpload will present a dialog asking you to specify the local directory because the local path ends with a colon and FTPUpload is looking for the name of the directory to be uploaded.

FTPUpload presents a dialog asking you to specify the local directory in the following cases:

1. You use the /I (interactive) flag.
2. The specified directory (TestDir1 in the example above) or any of its parents do not exist.

If you don't have permission to remove and to create directories on the server, FTPUpload will fail and return an error.

Creating a Directory

The following commands create a new directory on an FTP server:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/newDirectory1"
FTPCreateDirectory/U="ftpTestAccount"/W="dropbox" url
```

If the /pub/test/newDirectory1 directory already exists on the server, this command does nothing. This is not treated as an error, though the V_Flag output variable is set to -1 to indicate that the directory already existed.

If you don't have permission to create directories on the server, FTPCreateDirectory fails and returns an error.

Deleting a Directory

The following commands delete a directory on an FTP server:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/oldDirectory1"
FTPDelete/D/U="ftpTestAccount"/W="dropbox" url
```

If you don't have permission to delete directories on the server, or if the specified directory does not exist on the server, FTPDelete fails and returns an error.

FTP Transfer Types

The FTP protocol supports two types of transfers: image and ASCII. Image transfer is appropriate for binary files. ASCII transfer is appropriate for text files.

In an image transfer, also called a binary transfer, the data on the receiving end will be a replica of the data on the sending end. In an ASCII transfer, the receiving FTP agent changes line terminators to match the local convention. On Macintosh and Unix, the conventional line terminator is linefeed (LF, ASCII code 0x0A). On Windows, it is carriage-return plus linefeed (CR+LF, ASCII code 0x0D + ASCII code 0x0A).

If you transfer a text file using an image transfer, the file may not use the local conventional line terminator, but the data remains intact. Igor Pro can display text files that use any of the three conventional line terminators, but some other programs, especially older programs, may display the text incorrectly.

On the other hand, if you transfer a binary file, such as an Igor experiment file, using an ASCII transfer, the file will almost certainly be corrupted. The receiving FTP agent will convert any byte that happens to have the value 0x0D to 0x0A or vice versa. If the local convention calls for CRLF, then a single byte 0x0D will be changed to two bytes, 0x0D0A. In either case, the file will become unusable.

FTP Troubleshooting

FTP involves a lot of hardware and software on both ends and a network in between. This provides ample opportunity for errors.

Here are some tips if you experience errors using the FTP operations.

1. Use an FTP client or web browser to connect to the FTP site. This confirms that your network is operating, the FTP server is operating, and that you are using the correct URL.
2. Use an FTP client or web browser to verify that the user name and password that you are using is correct or that the server allows anonymous FTP access.

   Many web browser accept URLs of the form:

   ```
   ftp://username:password@ftp.example.com
   ```

   However the password is not transferred securely.
3. Use an FTP client or web browser to verify that the directory structure of the FTP server is what you think it is.
4. Using an FTP client or web browser, do the operation that you are attempting to do with Igor. This verifies that you have sufficient permissions on the server.
5. Use /V=7 to tell the Igor operation to display status information in the history area.

6. Try the simplest transfer you can. For example, try to download a single file that you know exists on the server.
7. If you have access to the FTP server, examine the FTP server log for clues.

Hypertext Transfer Protocol (HTTP)

The **FetchURL** function supports simple URL requests over the Internet from web or FTP servers and to local files. For example, you can use FetchURL to get the source code of a web page in text form, and then process the text to extract specific information from the response.

HTTP Limitations

At this time, **FetchURL** and **BrowseURL** routines work with the HTTP protocol.

Currently not supported are features such as using network proxy servers, using the HTTP POST method to submit forms and upload files to a web server, and making secure network connections using the Secure Socket Layer (SSL) protocol.

Downloading a Web Page Via HTTP

This example uses FetchURL to download the contents of the WaveMetrics home page into a string, and then counts the number of times that the string "Igor" occurs in the text of the page.

```
Function DownloadWebPageExample()
   String webPageText = FetchURL("http://www.wavemetrics.com")
   if (numtype(strlen(webPageText)) == 2)
      Print "There was an error while downloading the web page."
   endif
   Variable count, pos
   do
      pos = strsearch(webPageText, "Igor", pos, 2)
      if (pos == -1)
         break    // No more occurrences of "Igor"
      else
         pos += 1
         count += 1
      endif
   while (1)
   Printf "The text \"Igor\" was found %d times on the web page.\r", count
End
```

Downloading a File Via HTTP

This example uses FetchURL to download a file from a web server. Because FetchURL does not support storing the downloaded data into a file directly, we store the data in memory and then use Igor to write that data to a file on disk.

Though the example uses a URL that begins with http://, FetchURL also supports ftp:// and file:///. You could use the code below with a different URL to download a file from an FTP server or even to access a local on-disk file.

```
Function DownloadWebFileExample()
   String url = "http://www.wavemetrics.net/IgorManual.zip"

   // Based on the URL, determine what the destination
   // file name should be. This will be the default in the
   // Save As... dialog.
   String urlStrParam = RemoveEnding(url, "/")
   Variable parts = ItemsInList(urlStrParam, "/")
   String destFileNameStr = StringFromList(parts - 1, urlStrParam, "/")
   if (strlen(destFileNameStr) < 1)
```

```
      Print "Error: Could not determine the name of the destination file."
      return 0
   endif

   Variable refNum
   Open/D/M="Save File As..."/T="????" refNum as destFileNameStr
   String fullFilePath = S_fileName

   if (strlen(fullFilePath) > 0) // No error and user didn't cancel in dialog.
      // Open the selected file so that it can later be written to.
      Open/Z/T="????" refNum as fullFilePath
      if (V_flag != 0)
         Print "There was an error opening the local destination file."
      else
         String response = FetchURL(url)
         Variable error = GetRTError(1)
         if (error == 0 && numtype(strlen(response)) == 0)
            FBinWrite refNum, response
            Close refNum
            Print "The file was successfully downloaded as " + fullFilePath
         else
            Close refNum
            DeleteFile/Z fullFilePath  // Clean up the empty file.
            Print "There was an error downloading the file."
         endif
      endif
   endif
End
```

Making a Query Via HTTP

Another use for HTTP requests is to get the server's response to a query. While it's not possible to upload files to a web server or simulate the submission of complicated web forms (these would require the HTTP POST method, which is not supported), many simple web forms use the HTTP GET method, which FetchURL supports. For example, you can simulate the submission of the basic Google search form using the following code.

```
Function WebQueryExample()
   String keywords
   String baseURL = "http://www.google.com/search"

   // Prompt the user to enter search keywords.
   Prompt keywords, "Search for"
   DoPrompt "", keywords
   if (V_flag == 1)           // User clicked cancel button.
      return 0
   endif

   // Pass the search terms through URLEncode to
   // properly percent-encode them.
   keywords = URLEncode(keywords)

   // Build the full URL.
   String url = ""
   sprintf url, "%s?q=%s", baseURL, keywords

   // Fetch the results.
   String response
   response = FetchURL(url)
   Variable error = GetRTError(1)
   if (error != 0 || numtype(strlen(response)) != 0)
```

```
      Print "Error fetching search results."
      return -1
   endif

   // Try to extract the URL of the first result.
   String regExp = "<h3 class=\"r\">.+?href=\"(.+?)\".*"
   String firstURL
   SplitString/E=regExp response, firstURL
   if (V_flag == 1)
      BrowseURL firstURL
   else
      Print "Could not extract the first result from the"
      Print "results page. Your search terms might not"
      Print "have given any results, or the format of"
      Print "the results may have changed so that the"
      Print "first result cannot be extracted."
   endif
End
```

HTTP Troubleshooting

Here are some tips if you experience errors using **FetchURL**:

1. Use a web browser to connect to the site. This confirms that your network is operating, the server is operating, and that you are using the correct URL.
2. FetchURL generates an error if it cannot connect to the destination server, which could happen if your computer is not connected to the network or if the target URL contains an invalid host name or port number.

   However if the URL contains an invalid path or if the destination URL requires you to provide a username and password, FetchURL will likely not generate an error. The reason is these errors typically result in a web page being returned, though not the one you expected. If you need to check that a call to FetchURL returned a valid web page and not an error web page, you must do that in your own code. One possibility would be to try searching the page for key phrases, such as "File Not Found" or "Page Not Found".

Operation Queue

Igor supports an operation queue that allows for the execution of what were previously illegal operations. Items in the operation queue execute only when nothing else is happening. Macros and functions must not be running and the command line must be empty.

You may append to the operation queue using

`Execute/P <command string>`

The /P posts the command to operation queue. You can also specify the /Q (quiet) or /Z (ignore error) flags. See **Execute/P** operation (page V-145) for details about /Q and /Z.

The command string may be either special commands that are unique to the operation queue or may be ordinary Igor commands. The special commands are:

INSERTINCLUDE *procedureSpec*

DELETEINCLUDE *procedureSpec*

COMPILEPROCEDURES

NEWEXPERIMENT

LOADFILE *filePath*

MERGEEXPERIMENT *filePath*

INSERTINCLUDE and DELETEINCLUDE insert or delete #include lines in the main procedure window. *procedureSpec* is whatever you would use in a #include statement except for "#include" itself.

COMPILEPROCEDURES does just what it says, compiles procedures. You must call it after operations such as INSERTINCLUDE that modify, add, or remove procedure files.

NEWEXPERIMENT closes the current experiment without saving.

LOADFILE opens the file specified by *filePath*. *filePath* is either a full path or a path relative to the Igor Folder. The file may be any of a number of file types Igor can open. If the file is an experiment, be sure to execute NEWEXPERIMENT first to avoid putting up a dialog. If you want to save the changes in an experiment before loading another, you can use the standard SaveExperiment operation.

MERGEEXPERIMENT merges the experiment file specified by *filePath* into the current experiment. Before using this, make sure you understand the caveats regarding merging experiments. See **Merging Experiments** on page II-32 for details.

Note: The special operation queue keywords must be all caps and must have one space after the keyword.

Here is an example:

```
Function DemoQueue()
   Execute/P "INSERTINCLUDE <Multi-peak fitting 1.3>"
   Execute/P "INSERTINCLUDE <Peak Functions>"
   Execute/P "COMPILEPROCEDURES "
   Execute/P "CreateFitSetupPanel()"
   Execute/P "Sleep 00:00:04"
   Execute/P "NEWEXPERIMENT "
   Execute/P "LOADFILE :Examples:Feature Demos:Live mode.pxp"
   Execute/P "DoWindow/F Graph0"
   Execute/P "StartButton(\"StartButton\")"
End
```

In the above example, the example experiment Live mode.pxp was chosen because it happened to have a .pxp extension which allows the example to work on both Macintosh and Windows — the file name and path must be exact.

One important use of the operation queue is providing easy access to useful procedure packages. The "Igor Pro Folder/Igor Procedures" folder contains a procedure file that has Menu definitions similar to the following (**Caution**! The three commands under the example submenu are very long and are wrapped to fit on the page):

```
Menu "Analysis"
    Submenu "Packages"
        "Multipeak Fitting",Execute/P "INSERTINCLUDE  <Multi-peak fitting 1.3>";Execute/P
"INSERTINCLUDE  <Peak Functions>";Execute/P "COMPILEPROCEDURES ";Execute/P "CreateFitSetupPanel()"
        "Wave Arithmetic",Execute/P "INSERTINCLUDE  <Wave Arithmetic Panel>";Execute/P
"COMPILEPROCEDURES ";Execute/P "InitWaveArith()"
        "Probability Graph",Execute/P "INSERTINCLUDE  <Probability Graph>";Execute/P
"COMPILEPROCEDURES ";Execute/P " Probability_Axis()"
    End
End
```

To try this out, start Igor and choose one of the items from the Analysis→Packages menu.

User-Defined Hook Functions

Igor Pro will call specific user-defined functions, called "hook" functions, if they exist, when Igor Pro performs certain actions. Hook functions allow savvy programmers to customize Igor's behavior. In some cases the hook function may inform Igor that the action has been completely handled, and that Igor shouldn't perform the action. For example, you could write a hook function to load data from a certain kind of text file that Igor can not handle directly.

This section discusses general hook functions that do not apply to a particular window. For information on window-specific events, see Window Hook Functions.

There are two ways to get Igor to call your general hook function. The first is by using a predefined function name. For example, if you create a function named AfterFileOpenHook, Igor will automatically call it after opening a file. The second way is to explicitly tell Igor that you want it to call your hook using the **SetIgorHook** operation.

If you use a predefined hook function name, you should make the function static (private to the file containing it) so that other procedure files can use the same predefined name. This is discussed under **Static Hook Functions** (see page IV-263).

Here are the predefined hook functions.

Action	Hook Function Called
Procedures have been successfully compiled	**AfterCompiledHook**
A file or experiment has just been opened	**AfterFileOpenHook**
A target window has been created	**AfterWindowCreatedHook**
The Debugger window is about to open	**BeforeDebuggerOpensHook**
An experiment is about to be saved	**BeforeExperimentSaveHook**
A file or XOP is about to be opened	**BeforeFileOpenHook**
Igor about to open a new experiment	**IgorBeforeNewHook**
Igor about to quit	**IgorBeforeQuitHook**
Igor building and enabling menus or about to handle a menu selection	**IgorMenuHook**
Igor quitting	**IgorQuitHook**
Igor starting or new experiment	**IgorStartOrNewHook**

To create hook functions, you must write functions with the specified names and store them in any procedure file. If you store the procedure file in "Igor Pro User Files/Igor Procedures" (see **Igor Pro User Files** on page II-46 for details), Igor will automatically open the file and compile the functions when it starts up and will execute the IgorStartOrNewHook function if it exists.

You can use BeforeFileOpenHook to load your own custom data files via drag-and-drop. Your BeforeFileOpenHook function must detect your type of file by examining the file's type and creator codes or by examining its contents. If the file is of the right type, you then call your XOP or use the FBinRead or FReadLine operation to load data from the file. You then avoid opening the file by returning a value of 1. If the file is not your file, you return 0, which loads the file. See the examples in the **BeforeFileOpenHook** operation (page IV-259) description.

Windows system files with .bin, .com, .dll, .exe, and .sys extensions aren't passed to the hook functions.

This example checks the type of file being opened. If it is an Excel file, it loads the file using the XLLoadWave XOP. It is intended to allow you to load an Excel file by dragging its icon onto the Igor Pro application icon.

```
static Function BeforeFileOpenHook(refNum,fileName,path,type,creator,kind)
   Variable refNum,kind
   String fileName,path,type,creator

   String xop="XLLoadWave"    // name of XOP command to load data
   Variable isExcel,handledOpen=0

   // This tests the file name extension.
   String extension = ParseFilePath(4, fileName, ":", 0, 0)
   isExcel = CmpStr(extension, "xls")==0

   // This tests the Macintosh file type.
   // "XLS ", XLS3, XLS4, XLS5, XLW4, XLW5 are Excel file types
   isExcel += CmpStr(type[0,2],"XLS")==0
   isExcel += CmpStr(type[0,2],"XLW")==0
```

```
   if (isExcel)
      if (exists(xop)==4)  // Load only if XOP installed
         Close refNum
         String cmd
         cmd = xop + "/A/T/P="+path+" \""+fileName+"\""
         Execute cmd
         handledOpen=1     // we handled the open event
      endif
   endif

   return handledOpen   // 1 tells Igor not to open the file itself
End
```

A return value of 1 indicates that you handled the open file event and that Igor should not open it. A return value of 0 specifies that you did not handle the event and that Igor should deal with it.

For more examples, see **BeforeFileOpenHook** on page IV-259.

Another possible use of a hook function is to predefine global variables, strings, waves, symbolic paths, or data folders when a new experiment is started up:

```
static Function IgorStartOrNewHook(igorApplicationNameStr)
   String igorApplicationNameStr

   NewPath/O pathToMyData "HD:My Data:"
   Variable/G root:V_no_MIME_TSV_Load = 1 // See AfterFileOpenHook
   Make/O/T root:TestNames={"RDC #1","KLZ #2","ARB #3","MOR #4"}
End
```

The following sections describe the individual hook functions in detail.

AfterCompiledHook

AfterCompiledHook(*refNum*, *fileNameStr*, *pathNameStr*, *fileTypeStr*, *fileCreatorStr*, *fileKind*)

AfterCompiledHook is a user-defined function that Igor calls after the procedure windows have all been compiled successfully.

You can use AfterCompiledHook to initialize global variables or data folders, among other things.

The function result from AfterCompiledHook must be 0. All other values are reserved for future use.

See Also

SetIgorHook, **User-Defined Hook Functions** on page IV-251.

AfterFileOpenHook

AfterFileOpenHook(*refNum*, *fileNameStr*, *pathNameStr*, *fileTypeStr*, *fileCreatorStr*, *fileKind*)

AfterFileOpenHook is a user-defined function that Igor calls *after* it has opened a file or experiment that the user has double-clicked or dragged onto the Igor icon, or a file opened as a result of an "open" Apple event from another program (such as a Web browser).

Note: AfterFileOpenHook is not called when the Open File or Load Waves menus are selected.

The parameters contain information about the file, which has already been opened for read-only access.

AfterFileOpenHook's return value is ignored unless *fileKind* is 9. If the returned value is zero, the default action is performed.

Parameters

Variable *refNum* is the file reference number. You use this number with the **FReadLine**, **FStatus**, **FSetPos**, **FBinWrite**, **FBinRead**, **fprintf**, and **wfprintf** operations to read from or write to the file. Normally, the file is opened for read-only operations, but for experiment files and XOP files, *refNum* will be -1, meaning the file has not been opened for you. You can close the file and reopen it for write access, if you wish.

Igor always closes the file when the user-defined function returns, and *refNum* becomes invalid (don't store the value of *refNum* in a global for use by other routines, since the file it refers to has been closed).

String *fileNameStr* contains the name of the file (including any extension).

String *pathNameStr* contains the name of the symbolic path. *pathNameStr* is not the value of the path. Use the PathInfo operation to determine the path's value.

String *fileTypeStr* contains the file type. This was conceived with the Macintosh in mind. Under Windows, this is usually the file extension, such as ".txt". However, if the file is an Igor-registered file, then *fileTypeStr* is set to one of the Macintosh file type codes (for cross-platform compatibility). Some Igor-registered files types are listed in the following table:

Type of File	*fileTypeStr* Contents		Extension
Igor Experiment, packed	IGsU		.pxp
Igor Experiment, packed, stationery/template	IGsS		.pxt
Igor Experiment, unpacked	IGSU		.uxp
Igor Experiment, unpacked, stationery/template	IGSS		.uxt
Igor XOP	IXOP		.xop
Igor Procedure	TEXT		.ipf
Igor Notebook (formatted)	WMT0	(zero, not oh)	.ifn
Igor Notebook (unformatted)	TEXT		.txt
Igor Notebook stationery/template (formatted)	WMTS		.ift
Igor Text (data and commands)	TEXT		.itx *or* .awav
Igor Binary	IGBW		.ibw *or* .bwav
Igor Published Edition	edtp		
Igor Help	WMT0	(zero, not oh)	.ihf

In addition, some other nonregistered extensions are converted to Mac-like file types:

Type of File	*fileTypeStr*		Extension
Encapsulated PostScript	EPS	(trailing space)	.eps *or* .epsf
Rich Text	RTF	(trailing space)	.rtf
Internet Shortcut	LINK		.url*
Text (also unformatted Igor Notebook)	TEXT		.txt
Batch file	TEXT		.bat
ASCII or data	TEXT		.csv, .dat, *or* .tsv

* The .url extension isn't shown in Windows Explorer windows.

Regardless of the value of *fileTypeStr*, the *fileNameStr* parameter has the file name and the extension.

String *fileCreatorStr* contains the creator code. Also conceived with the Macintosh in mind, this is usually "IGR0" for Igor-registered files, the full file path to the application registered to open the file, or the full file path to the file itself if unregistered by any application.

Some Windows examples are:

File	*fileCreatorStr*
My Experiment.pxp	IGR0 (zero, not oh)
My Igor Data.ibw	IGR0 (zero, not oh)
Better.bmp	C:\Program Files\MS\MSPAINT.EXE
AFile.bat	C:\Mine\AFile.bat

String *fileCreatorStr* contains the creator code. Some Macintosh examples are:

Application	*fileCreatorStr* Contents
Igor or Igor Pro	IGR0 (zero, not oh)
TeachText or SimpleText	ttxt

Variable *fileKind* is a number that identifies what kind of file Igor thinks it is. If the user's AfterFileOpenHook routine returns 0, Igor performs the Default Action listed in the table:

Kind of File	*fileKind*	Default Action, if Any
Unknown	0	
Igor Experiment, packed (stationery, too)	1	
Igor Experiment, unpacked (stationery, too)	2	
Igor XOP	3	
Igor Binary File	4	
Igor Text (data and commands)	5	
Text, no numbers detected in first two lines	6	
General Numeric text (no tabs)	7	
Numeric text Tab-Separated-Values	8	
Numeric text Tab-Separated-Values, MIME	9	Display loaded data in a new table and a new graph.
Text, with tabs	10	
Igor Notebook (unformatted or formatted)	11	
Igor Procedure	12	
Igor Help	13	

Details

AfterFileOpenHook's return value is ignored, except when *fileKind* is 9 (Numeric text, Tab-Separated-Values, MIME). If you return a value of 0, Igor executes the default action, which displays the loaded data in a table and a graph. If you return a value of 1, Igor does nothing.

Note: Another way to disable the MIME-TSV default action is define a global variable named V_no_MIME_TSV_Load (in the root data folder) and set its value to 1. In this case any file of *fileKind* = 9 is reassigned a *fileKind* of 8.

The default action for *fileKind* = 9 makes Igor a MIME-TSV document Helper Application for Web browsers such as Netscape or Internet Explorer.

The exact criteria for Igor to consider a file to be of kind 9 are:

- *fileTypeStr* must be "TEXT" or "WMT0" (that's a zero, not an oh).
- Either the first line of the file must begin with a # character, or the name of the file must end with ".tsv" in either lower or upper case.
- The first line must contain one or more column titles. If the line starts with a # character, the first column title must not start with "include", "pragma" or the ! character. Spaces are allowed in the titles, but if two or more title columns are present, they must be separated by one tab character.
- The second line must contain one or more numbers. If two or more numbers, they must be separated by one tab character, and the first line's words must also be separated by tabs.

When the MIME-TSV file contains one column of data, it is graphed as a series of Y values.

Short columns (less than 50 values) are graphed with lines and markers, longer columns with lines only. Preferences are turned on when the graph is made.

Two columns are assumed to be X followed by Y, and are graphed as Y versus X. More columns do not affect the graph, though they are shown in the table.

Example

```
// This hook function prints the first line of opened TEXT files
// into the history area
Function AfterFileOpenHook(refNum,file,pathName,type,creator,kind)
   Variable refNum,kind
   String file,pathName,type,creator
   // Check that the file is open (read only), and of correct type
   if( (refNum >= 0) && (CmpStr(type,"TEXT")==0) )  // also "text", etc.
      String line1
      FReadLine refNum, line1 // Read the line (and carriage return)
      Print line1       // Print line in the history window.
   endif
   return 0             // don't prevent MIME-TSV from displaying
End
```

BeforeFileOpenHook and **SetIgorHook**.

BeforeDebuggerOpensHook

BeforeDebuggerOpensHook(*errorInRoutineStr, stoppedByBreakpoint*)

BeforeDebuggerOpensHook is a user-defined function that Igor calls when the debugger window is about to be opened, whether by hitting a breakpoint or when Debug on Error is enabled.

BeforeDebuggerOpensHook can be used to prevent the debugger window opening for certain error codes or in selected user-defined functions when Debug on Error is enabled. This is a feature for advanced programmers only. Most programmers will not need it.

This hook does not work well for macros or procs, because their runtime errors don't automatically open the debugger, but instead present an error dialog from which the user manually enters the debugger by clicking the Debug button.

Parameters

String *errorInRoutineStr* contains the name of the routine (function or macro) the debugger will be stopping in as a fully-qualified name, comprised of at least "`ModuleName#RoutineName`", suitable for use with FunctionInfo.

If the routine is in a regular module procedure window (see **Regular Modules** on page IV-212), *errorInRoutineStr* will be a triple name such as "`MyIM#MyModule#MyFunction`".

Variable *stoppedByBreakpoint* is 0 if the debugger is about to be shown because of Debug on Error, or non-zero if the debugger encountered a user-set breakpoint (see **Setting Breakpoints** on page IV-185).

If a breakpoint exists at the line where an error caused the debugger to appear, *stoppedByBreakpoint* will be non-zero, even though the cause was Debug on Error.

Details

If BeforeDebuggerOpensHook returns 0 or NaN (or doesn't return a value), the debugger window is opened normally.

If it returns 1, the debugger window is not shown and program execution continues.

All other return values are reserved for future use.

Example

The following hypothetical example:

1. Prevents breakpoints from bringing up the debugger, unless DEBUGGING is defined.
2. Prints the name of the routine with the error, and the error message.
3. Beeps before the debugger appears.

```
Function ProvokeDebuggerInFunction()
   DebuggerOptions enable=1, debugOnError=1     // Enable debug on error

   ProvokeDebugger()
End

Function ProvokeDebugger()
   Variable var=0 // Put a breakpoint here.
                  // Without a #define DEBUGGING, the breakpoint is skipped.
   Make/O $""     // Cause an error
   Print "Back from bad Make command in function"
End

static Function BeforeDebuggerOpensHook(pathToErrorFunction,isUserBreakpoint)
   String pathToErrorFunction
   Variable isUserBreakpoint

   #ifndef DEBUGGING
      if( isUserBreakpoint )
         return 1 // Ignore user breakpoints we forgot to clear.
                  // Don't use this during development!
      endif
   #endif

   Print "stackCrawl = ", GetRTStackInfo(0)
   Print "FunctionInfo = ", FunctionInfo(pathToErrorFunction)

   // Don't clear errors unless you're preventing the debugger from appearing
   Variable clearErrors= 0
   Variable rtErr= GetRTError(clearErrors)   // Get the error #

   Variable substitutionOption= exists(pathToErrorFunction)== 3 ? 3 : 2
   String errorMessage= GetErrMessage(rtErr,substitutionOption)

   Beep     // Audible cue that the debugger is showing up!

   Print "Error \""+errorMessage+"\" in "+pathToErrorFunction+"

   return 0 // Return 0 to show the debugger; an unexpected error occurred.
End

•ProvokeDebuggerInFunction()  // Execute this in the command line
  stackCrawl =
      ProvokeDebuggerInFunction;ProvokeDebugger;BeforeDebuggerOpensHook;
  FunctionInfo =
      NAME:ProvokeDebugger;PROCWIN:Procedure;MODULE:;INDEPENDENTMODULE:;...
```

```
Error "Expected name" in ProcGlobal#ProvokeDebugger
Back from bad Make command in function
```

Conditional Compilation on page IV-86

AfterWindowCreatedHook

AfterWindowCreatedHook(*windowNameStr, winType*)
AfterWindowCreatedHook is a user-defined function that Igor calls when a target window is first created.

AfterWindowCreatedHook can be used to set a window hook on target windows created by the user or by other procedures.

Parameters
String *windowNameStr* contains the name of the created window.

Variable *winType* is the type of the window, the same value as returned by **WinType**.

Details
"Target windows" are graphs, tables, layout, panels, and notebook windows.

AfterWindowCreatedHook is not called when an Igor experiment is being opened.

Igor ignores the value returned by AfterWindowCreatedHook.

See Also
SetWindow, **SetIgorHook**, and **User-Defined Hook Functions** on page IV-251.

BeforeExperimentSaveHook

BeforeExperimentSaveHook(*refNum, fileNameStr, pathNameStr, fileTypeStr, fileCreatorStr, fileKind*)
BeforeExperimentSaveHook is a user-defined function that Igor calls when an experiment is about to be saved by Igor.

Igor ignores the value returned by BeforeExperimentSaveHook.

Parameters
For a full explanation of the parameters, see **AfterFileOpenHook** on page IV-253.

Variable *refNum* is -1. The experiment file is not open.

String *fileNameStr* contains the name of the experiment file (including any extension).

String *pathNameStr* contains the name of the symbolic path.

String *fileTypeStr* contains the file type code.

String *fileCreatorStr* contains the file creator code.

Variable *fileKind* is a number that identifies what kind of file Igor will be saving:

Kind of File	*fileKind*
Igor Experiment, packed*	1
Igor Experiment, unpacked*	2

* Including stationery experiment files.

Details
You can determine the full directory and file path of the experiment by calling the **PathInfo** operation with $*pathNameStr*.

Example

This (somewhat frivolous) example prints the full file path of the about-to-be-saved experiment to the history area, and deletes all unused symbolic paths.

```
#pragma rtGlobals=1        // treat S_path as local string variable

Function BeforeExperimentSaveHook(rN,fileName,path,type,creator,kind)
    Variable rN,kind
    String fileName,path,type,creator

    PathInfo $path             // puts path value into (local) S_path
    Printf "Saved “%s” experiment\r",S_path+fileName

    KillPath/A/Z               // Delete all unneeded symbolic paths
End
```

See Also

The **SetIgorHook** operation.

BeforeFileOpenHook

BeforeFileOpenHook(*refNum, fileNameStr, pathNameStr, fileTypeStr, fileCreatorStr, fileKind*)

BeforeFileOpenHook is a user-defined function that Igor calls when a file *is about to be opened* by Igor because the user dragged it onto the Igor icon, double-clicked it, or because Igor received an “open” Apple event from another program (such a Web browser).

Note: BeforeFileOpenHook is not called when the Open File or Load Waves menu is selected.

The parameters contain information about the file, which has already been opened for read-only access.

The value returned by BeforeFileOpenHook informs Igor whether the user-defined function handled the open and therefore Igor should not perform its default action. In some cases, this return value is ignored, and Igor performs the default action anyway.

Parameters

(For a full explanation of the parameters, see **AfterFileOpenHook** on page IV-253.)

Variable *refNum* is the file reference number.

String *fileNameStr* contains the name of the file (including any extension).

String *pathNameStr* contains the name of the symbolic path.

String *fileTypeStr* contains the file type code.

String *fileCreatorStr* contains the file creator code.

Variable *fileKind* is a number that identifies what kind of file Igor thinks it is:

Kind of File	*fileKind*	Default Action, if Any
Unknown	0	
Igor Experiment, packed *	1	(Hook not called)
Igor Experiment, unpacked*	2	(Hook not called)
Igor XOP	3	
Igor Binary file	4	Data loaded
Igor Text (data and commands)	5	Data loaded, commands executed
Text, no numbers detected in first two lines	6	Opened as unformatted notebook
General Numeric text (no tabs)	7	Data loaded as general text
Numeric text Tab-Separated-Values	8	Data loaded as delimited text
Numeric text Tab-Separated-Values, MIME	9	Display loaded data in a new table and a new graph.

Kind of File	*fileKind*	Default Action, if Any
Text, with tabs	10	Opened as unformatted notebook
Igor Notebook (unformatted or formatted)	11	Opened as notebook
Igor Procedure	12	*Always* opened as procedure file
Igor Help	13	*Always* opened as help file

* Including stationery experiment files.

Details

BeforeFileOpenHook must return 1 if Igor is not to take action on the file (it won't be opened), or 0 if Igor is permitted to take action on the file. Igor ignores the return value for *fileKind* values of 3, 12, and 13. The hook function is not called for Igor experiments (*fileKind* values of 1 and 2).

Igor always closes the file when the user-defined function returns, and *refNum* becomes invalid (don't store the value of *refNum* in a global for use by other routines, since the file it refers to has been closed).

Example

This example checks the first line of the file about to be opened to determine whether it has a special, presumably user-specific, format. If it does, then LoadMyFile (another user-defined function) is called to load it. LoadMyFile presumably loads this custom data file, and returns 1 if it succeeded. If it returns 0 then Igor will open it using the Default Action from the above table.

Another example can be found in the discussion in **User-Defined Hook Functions** on page IV-251.

```
Function BeforeFileOpenHook(refNum,fileName,path,type,creator,kind)
   Variable refNum,kind
   String fileName,path,type,creator

   Variable handledOpen=0
   if( CmpStr(type,"TEXT")==0 )              // text files only
      String line1
      FReadLine refNum, line1 // First line (and carriage return)
      if( CmpStr(line1[0,4],"XYZZY") == 0 )  // My special file
         FSetPos refNum, 0             // rewind to start of file
         handledOpen= LoadMyFile(refNum)  // returns 1 if loaded OK
      endif
   endif
   return handledOpen   // 1 tells Igor not to open the file
End
```

See Also

AfterFileOpenHook and **SetIgorHook**.

IgorBeforeNewHook

IgorBeforeNewHook(*igorApplicationNameStr*)

IgorBeforeNewHook is a user-defined function that Igor calls before a new experiment is opened in response to the New Experiment, Revert Experiment, or Open Experiment menu items in the File menu.

You can use IgorBeforeNewHook to clean up the current experiment, or to avoid losing unsaved data even if the user chooses to not save the current experiment.

Igor ignores the value returned by IgorBeforeNewHook.

Parameters

igorApplicationNameStr contains the name of the currently running Igor Pro application.

See Also

IgorStartOrNewHook and **SetIgorHook**.

IgorBeforeQuitHook

IgorBeforeQuitHook(*unsavedExp*,*unsavedNotebooks*,*unsavedProcedures*)

IgorBeforeQuitHook is a user-defined function that Igor calls just before Igor is about to quit (before any save-related dialogs have been presented).

Parameters

Variable *unsavedExp* is 0 if the experiment is saved, 1 if unsaved.

Variable *unsavedNotebooks* is the count of unsaved notebooks.

Variable *unsavedProcedures* is the count of unsaved procedures.

Note: The save state of packed procedure and notebook files is part of *unsavedExp*, not *unsavedNotebooks* or *unsavedProcedures*. This applies to adopted procedure and notebook files and new procedure and notebook windows that have never been saved.

Details

IgorBeforeQuitHook will normally return 0. In these cases it will present the "Do you want to save" dialogs, and if the user approves, it will call IgorQuitHook.

If IgorBeforeQuitHook returns 1, then the current experiment, notebooks, or procedures will not be saved; no dialogs will be presented to the user, and it will not call IgorQuitHook.

IgorQuitHook and **SetIgorHook**.

IgorMenuHook

IgorMenuHook(*isSelection, menuStr, itemStr, itemNo, topWindowNameStr, wType*)

IgorMenuHook is a user-defined function that Igor calls just before and just after menu selection (whether by mouse or keyboard).

Parameters

Variable *isSelection* is 0 before a menu item has been selected, 1 when a menu item has been selected.

String *menuStr* is the name of the selected menu (in English and as used by SetIgorMenuMode). *menuStr* is "" when *isSelection* is 0.

String *itemStr* is the name of the selected menu item or "" when *isSelection* is 0.

Variable *itemNo* is the item number of the selected menu item; 1 is the first item in the selected menu. *itemNo* is 0 when *isSelection* is 0.

String *topWindowNameStr* is the name of the top window (the window to which window-specific menu commands like Copy and Paste apply).

Not all windows have names, so *topWindowNameStr* is set specially in those cases:

Window	***topWindowNameStr***
graph, panel, notebook, layout, table	Window name. See the Window Control Dialog and **DoWindow** operation (page V-122) about window names.
command/history window	"kwCmdHist" (as used for **GetWindow**).
procedure window	The window title as shown in the window's title bar. The standard procedure window is "Procedure".
Igor Extensions ("XOP") window	The window title as shown in the window's title bar.

Variable *wType* identifies the kind of window that *topWindowNameStr* names. It returns the same values as the **WinType** function (see page V-744). For procedure windows *wType* is 8, for the command/history window it is -1, and for XOP windows or unknown windows *wType* is 0.

Details

IgorMenuHook is called with *isSelection* set to 0 after all the menus have been enabled and before a mouse click or Command-key (*Macintosh*) or Ctrl+key (*Windows*) is handled.

The return value should normally be 0. If the return value is nonzero (1 is usual) then the top window's hook function (see **SetWindow** operation on page V-569) is not called for the enablemenu event.

IgorMenuHook is called with *isSelection* set to 1 after the menu has been selected and before Igor has acted on the selection.

If the hook function returns 0, Igor proceeds to call the top window's hook function for the menu event. (If the window hook function is present and returns nonzero Igor ignores the menu selection, otherwise Igor handles the menu selection normally.)

If the hook function returns nonzero (1 is again usual), Igor does not call the remaining hook functions and Igor ignores the menu selection.

Menu Event Details

Menu building, enabling, and selection by Igor, user menus, window hooks and IgorMenuHook are sequenced this way:

Menu building and enabling are performed in this order:

1. Igor updates built-in menus according to the frontmost and the target window.
2. Dynamic user-defined menus are updated.
3. IgorMenuHook(0, …) is called. If IgorMenuHook returns nonzero (which is not recommended), step 4 is skipped.
4. The top window's window hook functions (see **SetWindow** operation on page V-569) are called with the enablemenu event. The return value is ignored.
5. Igor extensions update their menus and their items in built-in menus.

Menu selections are handled in this order:

1. Igor extensions may handle the menu selection. If the selection was handled, the following steps are skipped.
2. If the selected menu item is not one of Igor's built-in menus, the steps 3 and 4 are skipped.
3. The top window's window hook(s) is (are) called with the menu event. If a hook returns nonzero the remaining window hooks and the following steps are skipped.
4. IgorMenuHook(1, …) is called. If IgorMenuHook returns nonzero, the following steps are skipped.
5. If a user-defined menu was chosen, Igor executes the associated command, and the remaining step is skipped.
6. Igor handles the selection of a built-in menu item.

Example

This user hook function invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for all graphs, preventing Igor from performing the usual Copy.

```
Function IgorMenuHook(isSel, menuStr, itemStr, itemNo, topWindowName, wt)
    Variable isSel
    String menuStr, itemStr
    Variable itemNo
    String topWindowName
    Variable wt

    Variable handled= 0
    if( Cmpstr(menuStr,"Edit") == 0 && CmpStr(itemStr,"Copy") == 0 )
        if( wt == 1 )                                   // graph
            // DoIgorMenu would cause recursion, so we defer execution
            Execute/P/Q/Z "DoIgorMenu \"Edit\", \"Export Graphics\""
            handled= 1
        endif
    endif

    return handled
End
```

See Also

SetWindow, **Execute**, and **SetIgorHook**.

IgorQuitHook

IgorQuitHook(*igorApplicationNameStr*)

IgorQuitHook is a user-defined function that Igor calls when Igor is about to quit.

The value returned by IgorQuitHook is ignored.

Parameters

String *igorApplicationNameStr* contains the name of the currently running Igor Pro application (including the .exe extension under Windows).

Details

You can determine the full directory and file path of the Igor application by calling the **PathInfo** operation with the Igor path name. See the example in **IgorStartOrNewHook** on page IV-263.

See Also

IgorBeforeQuitHook and **SetIgorHook**.

IgorStartOrNewHook

IgorStartOrNewHook(*igorApplicationNameStr*)

IgorStartOrNewHook is a user-defined function that Igor calls when starting up and when creating a new experiment. It is also called if Igor is launched as a result of double-clicking a saved Igor experiment.

Igor ignores the value returned by IgorStartOrNewHook.

Parameters

String *igorApplicationNameStr* contains the name of the currently running Igor Pro application (including the .exe extension under Windows).

Details

You can determine the full directory and file path of the Igor application by calling the **PathInfo** operation with the Igor path name.

Example

This example prints the full path of Igor application and sets the annotation halo size to zero whenever Igor starts up or creates a new experiment:

```
#pragma rtGlobals=1        // treat S_path as local string variable

Function IgorStartOrNewHook(igorApplicationNameStr)
   String igorApplicationNameStr

   Variable/G root:V_TBBufZone= 0  // See General Annotation Properties
                                   // on page III-48
   PathInfo Igor              // puts path value into (local) S_path
   printf "“%s” (re)starting\r", S_path + igorApplicationNameStr
End
```

See Also

IgorBeforeNewHook and **SetIgorHook**.

Static Hook Functions

To allow for multiple procedure files to define the same predefined hook function, you should declare your hook function static. For example:

```
static Function IgorStartOrNewHook(igorApplicationNameStr)
   String igorApplicationNameStr
```

The use of the static keyword makes the function private to the procedure file containing it and allows other procedure files to have their own static function with the same name.

Igor calls static hook functions after the **SetIgorHook** (see page V-560) functions are called. The static hook functions themselves are called in the order in which their procedure file was opened. You should not rely on any execution order among the static hook functions. However, any hook function which returns a

nonzero result prevents remaining hook functions from being called and prevents Igor from performing it's usual processing of the hook event. In most cases hook functions should exercise caution in returning any value other than 0. For hook functions only, returning a NaN or failing to return a value (which returns a NaN) is considered the same as returning 0.

The **IgorStartOrNewHook** (see page IV-263) hook function is especially useful to initialize a related set of procedures packaged together in an auxiliary procedure file.

Window Hook Functions

A window hook function is a user-defined function that receives notifications of events that occur in a specific window. Your window hook function can detect and respond to events of interest. You can then allow Igor to also process the event or inform Igor that you have handled it.

This section discusses window hook functions that apply to a specific window. For information on general events hooks, see **User-Defined Hook Functions** on page IV-251.

To handle window events, you first write a window hook function and then use the **SetWindow** operation to install the hook on a particular window. This example shows how you would detect arrow key events in a particular window. To try it, paste the code below into the procedure window and then execute DemoWindowHook():

```
Function MyWindowHook(s)
   STRUCT WMWinHookStruct &s

   Variable hookResult = 0 // 0 if we do not handle event, 1 if we handle it.

   switch(s.eventCode)
      case 11:              // Keyboard event
         switch (s.keycode)
            case 28:
               Print "Left arrow key pressed."
               hookResult = 1
               break
            case 29:
               Print "Right arrow key pressed."
               hookResult = 1
               break
            case 30:
               Print "Up arrow key pressed."
               hookResult = 1
               break
            case 31:
               Print "Down arrow key pressed."
               hookResult = 1
               break
         endswitch
         break
   endswitch

   return hookResult // If non-zero, we handled event and Igor will ignore it.
End

Function DemoWindowHook()
   DoWindow/F DemoGraph    // Does graph exist?
   if (V_flag == 0)
      Display /N=DemoGraph // Create graph
      SetWindow DemoGraph, hook(MyHook)=MyWindowHook  // Install window hook
   endif
End
```

The window hook function receives a WMWinHookStruct structure as a parameter. WMWinHookStruct is a built-in structure that contains all of the information you might need to respond to an event. One of its fields, the eventCode field, specifies what kind of event occurred.

If your hook function returns 1, this tells Igor that you handled the event and Igor does not handle it. If your hook function returns 0, this tells Igor that you did not handle the event, so Igor does handle it.

This example uses a named window hook. In this case the name is MyHook. More than one procedure file can install a hook on a given window. The purpose of the name is to allow a package to install and remove its own hook function without disturbing the hook functions of other packages. Choose a hook name that is unlikely to conflict with other hook names.

Earlier versions of Igor supported only one unnamed hook function. This meant that only one package could hook any particular window. Unnamed hook functions are still supported for backward compatibility but new code should always use named hook functions.

Window Hooks and Subwindows

Igor calls window hook functions for top-level windows only, not for subwindows. If you want to hook a subwindow, you must set the hook on the top-level window. In the hook function, test to see if the subwindow is active. For example, this code, at the start of a window hook function, insures that the hook runs only if a subwindow named G0 in a panel named Panel0 is active.

```
GetWindow $s.winName activeSW
String activeSubwindow = S_value
if (CmpStr(activeSubwindow, "Panel0#G0") != 0)
   return 0
endif
```

Named Window Hook Functions

A named window hook function takes one parameter - a `WMWinHookStruct` structure. This built-in structure provides your function with information about the status of various window events.

The named window hook function has this format:

```
Function MyWindowHook(s)
   STRUCT WMWinHookStruct &s

   Variable hookResult = 0

   switch(s.eventCode)
      case 0:              // Activate
         // Handle activate
         break

      case 1:              // Deactivate
         // Handle deactivate
         break

      // And so on . . .
   endswitch

   return hookResult       // 0 if nothing done, else 1
End
```

If you handle a particular event and you want Igor to ignore it, return 1 from the hook function.

Named Window Hook Events

Here are the events passed to a named window hook function:

eventCode	eventName	Notes
0	"Activate"	
1	"Deactivate"	
2	"Kill"	
3	"Mousedown"	
4	"Mousemoved"	
5	"Mouseup"	
6	"Resize"	
7	"Cursormoved"	See **Cursors — Moving Cursor Calls Function** on page IV-294.
8	"Modified"	A modification to the window has been made. This is sent to graph and notebook windows only. It is an error to try to kill a notebook window from the window hook during the modified event.
9	"Enablemenu"	
10	"Menu"	
11	"Keyboard"	
12	"moved"	
13	"renamed"	
14	"subwindowKill"	One of the window's subwindows is about to be killed.
15	"hide"	The window or one of its subwindows is about to be hidden.
16	"show"	The window or one of its subwindows is about to be unhidden.
17	"killVote"	Window is about to be killed. Return 2 to prevent the window from being killed, otherwise return 0. **Note**: Don't delete data structures during this event, use killVote only to decide whether the window kill should actually happen. Delete data structures in the kill event. See **Window Hook Deactivate, Kill, Show and Hide Events** on page IV-269.
18	"showTools"	
19	"hideTools"	
20	"showInfo"	
21	"hideInfo"	
22	"mouseWheel"	
23	"spinUpdate"	This event is sent only to windows marked via DoUpdate/E=1 as progress windows. It is sent when Igor spins the beachball cursor. See **Progress Windows** on page IV-134 for details.

WMWinHookStruct

The WMWinHookStruct structure has members as described in the following tables:

Base WMWinHookStruct Structure Members

Member	Description
char winName[MAX_PATH_LENGTH+1]	hcSpec of the affected (sub)window.
STRUCT Rect winRect	Local coordinates of the affected (sub)window.
STRUCT Point mouseLoc	Mouse location.
double ticks	Tick count when event happened.
Int32 eventCode	See see **eventCode** table on page IV-266.
char eventName[31+1]	Name-equivalent of eventCode, see **eventCode** table on page IV-266. Added in Igor 5.03.
Int32 eventMod	Bitfield of modifiers. See description for MODIFIERS:*flags*.

Members of WMWinHookStruct Structure Used with menu Code

Member	Description
char menuName[255+1]	Name of menu (in English) as used by **SetIgorMenuMode**.
char menuItem[255+1]	Text of the menu item as used by SetIgorMenuMode

Members of WMWinHookStruct Structure Used with keyboard Code

Member	Description
Int32 keycode	ASCII value of key struck. Function keys are not available but navigation keys are translated to specific values and will be the same on Macintosh and Windows.

Members of WMWinHookStruct Structure Used with cursormoved Code

Member	Description
char traceName[MAX_OBJ_NAME+1]	The name of the trace or image to which the moved cursor is attached or which supplies the X (and Y) values. Can be "" if the cursor is free.
char cursorName[2]	Cursor name A through J.
double pointNumber	Point number of the trace or the X (row) point number of the image where the cursor is attached. If the cursor is "free", pointNumber is actually the fractional relative *xValue* as used in the **Cursor**/F/P command.
double yPointNumber	Valid only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot, or when the cursor is free.

Members of `WMWinHookStruct` Structure Used with `cursormoved` Code

Member	Description
	If attached to an image, contour, or waterfall plot, `yPointNumber` is the Y (column) point number of the image where the cursor is attached. If the cursor is "free", `yPointNumber` is actually the fractional relative *yValue* as used in the **`Cursor`**`/F/P` command.
`Int32 isFree`	Has value of 1 if the cursor is not attached to anything, or value of 0 if it is attached to a trace, image, contour, or waterfall.

Members of `WMWinHookStruct` Structure Used with `mouseWheel` Code

Member	Description
`double wheelDy`	Vertical lines to scroll. Typically +1 or -1.
`double wheelDx`	Horizontal lines to scroll. Typically +1 or -1. On Windows, horizontal mouse wheel requires Vista.

Members of `WMWinHookStruct` Used with `renamed` Code

Member	Description
`char oldWinName[MAX_OBJ_NAME+1]`	Old name of the window or subwindow. Not the absolute path *hcSpec*, just the name.

User-Modifiable Members of `WMWinHookStruct` Structure

Member	Description
`Int32 doSetCursor`	Set TRUE to change cursor to that specified by `cursorCode`.
`Int32 cursorCode`	Standard cursor as set by hookcursor=*number*.

Set Cursor Hook Example

This example uses a named hook to set the cursor as the mouse is moved horizontally across the bottom half of the window:

```
static constant kUHC_mousemoved=4

Function MyWinHook(s)
   STRUCT WMWinHookStruct &s
   Variable rval= 0
   switch(s.eventCode)
      case kUHC_mousemoved:
         if( s.mouseLoc.v > ((s.winRect.top+s.winRect.bottom)/2) )
            s.doSetCursor= 1
            s.cursorCode=round(27*(s.mouseLoc.h-s.winRect.left) /
                                 (s.winRect.right-s.winRect.left))
            rval= 1           // we have taken over this event
         endif
         break
   EndSwitch
```

```
   return rval
End

Function DemoSetCursorHook()
   Make/O jack=x
   Display jack
   SetWindow kwTopWin,hook(testhook)= MyWinHook
End
```

Panel Done Button Example

This example uses a window hook and button action procedure to implement a panel dialog with a Done button such that the panel can't be closed by clicking the panel's close widget, but can be closed by the Done button's action procedure:

```
Proc ShowDialog()
   PauseUpdate; Silent 1         // building window...
   NewPanel/N=Dialog/W=(225,105,525,305) as "Dialog"
   Button done,pos={119,150},size={50,20},title="Done"
   Button done,proc=DialogDoneButtonProc
   TitleBox warning,pos={131,83},size={20,20},title=""
   TitleBox warning,anchor=MC,fColor=(65535,16385,16385)
   SetWindow Dialog hook(dlog)=DialogHook, hookevents=2
EndMacro

Function DialogHook(s)
   STRUCT WMWinHookStruct &s
   Variable statusCode= 0
      strswitch( s.eventName )
      case "killVote":
         TitleBox warning win=$s.winName, title="Press the Done button!"
         Beep
         statusCode=2                  // prevent panel from being killed.
         break
      case "mousemoved":               // to reset the warning
         TitleBox warning win=$s.winName, title=""
         break
   endswitch
   return statusCode
End

Function DialogDoneButtonProc(ba) : ButtonControl
   STRUCT WMButtonAction &ba
   switch( ba.eventCode )
      case 2:              // mouse up
         // turn off the named window hook
         SetWindow $ba.win hook(dlog)=$""
         // kill the window AFTER this routine returns
         Execute/P/Q/Z "DoWindow/K "+ba.win
         break
   endswitch
   return 0
End
```

Window Hook Deactivate, Kill, Show and Hide Events

The actions caused by these events (eventCode 2, 14, 15, 16 and 17) potentially affect multiple subwindows.

If you kill a subwindow, the root window's hook function(s) receives a subwindowKill event for that subwindow and any child subwindows.

If you kill a root window, the root window's hook function(s) receives a subwindowKill event for each child subwindow, and then the root window's hook function(s) receive a kill event.

Likewise, hiding and showing windows can result in subwindows being hidden or shown. In each case, the window hook function receives a hide or show event for each affected window or subwindow.

The winName member of WMWinHookStruct will be set to the full subwindow path of the subwindow that is affected.

Exterior subwindows are a special case because they are subwindows, but you can attach a hook function to an exterior subwindow. The hook function attached to the root window does not receive events affecting exterior subwindows. To handle subwindowKill, hide, or show events when an exterior subwindow is killed, hidden, or shown as a result of killing, hiding, or showing its parent window, you must have a hook function attached to the exterior subwindow.

As a further subtlety, the hook function(s) attached to an exterior subwindow will receive a subwindowKill event if the exterior subwindow is killed as a result of killing the parent window. But it will receive a regular kill event if it is killed directly. Normal subwindows always receive only subwindowKill events.

The kill-related events are sent in this order when a window or subwindow is killed:

1. A killVote event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed.
2. If the window is not a subwindow and wasn't created with /K=*k* the standard window close dialog appears. If the close is cancelled, the window is not killed, the window will receive an activate event when the dialog is dismissed, and no further events are generated. Otherwise, proceed to step 3.
3. If the window being killed has subwindows, starting from the bottom-most subwindow and working back toward the window being killed:

3a. If the subwindow is a graph or panel, action procedures for controls contained in the subwindow are called with event -1, "control being killed".

3b. The root window's hook function(s) receive a subwindowKill event for the subwindow. If any hook function returns 1, no further subwindow hook events or control being killed events are sent, but the window killing process continues.

Steps 3a and 3b are repeated for each subwindow until the window or subwindow being killed is reached.

4. If the killed window is a root window, a kill event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed. This method of preventing a window from closing is to be avoided: use the killVote event or the window-equivalent of `NewPanel/K=2`.

There are several ways to prevent a window being killed. You might want to do this in order to enforce use of a Done or Do It button, or to prevent killing a control panel while some hardware action is taking place.

The best method is to use /K=2 when creating the window (see **Display** or **NewPanel**). Then the only way to kill the window is via the DoWindow/K command, or KillWindow command. In general, you would provide a button that kills the window after checking for any conditions that would prevent it.

The KillVote event is more flexible but harder to use. It gives your code a chance to decide whether or not killing is allowed. This means the user can close and kill the window with the window close box when it is allowed.

Returning 2 for the window kill event is not recommended. If you have old code that uses this method, we strongly recommend changing it to return 2 for the killVote event. New code should never return 2 for the kill event.

Events 14-17 were added to Igor Pro version 6.02.

Unnamed Window Hook Functions

Unnamed window hook functions are supported for backward compatibility only. New code should use named window hook functions. See **Named Window Hook Functions** on page IV-265.

Each window can have one unnamed hook function. You designate a function as the unnamed window hook function using the **SetWindow** operation with the hook keyword.

The unnamed hook function is called when various window events take place. The reason for the hook function call is stored as an event code in the hook function's infoStr parameter.

The hook function is not called during experiment creation or load time so as to prevent the hook function from failing because the experiment is not fully recreated.

The hook function has the following syntax:

```
Function procName(infoStr)
   String infoStr
   String event= StringByKey("EVENT",infoStr)
   …
   return statusCode    // 0 if nothing done, else 1
End
```

`infoStr` is a string containing a semicolon-separated list of ***key:value*** pairs:

Key	Value
EVENT	*eventKey* See list of *eventKey* values below.
HCSPEC	Absolute path of the window or subwindow. See **Subwindow Command Concepts** on page III-95.
`MODIFIERS`	Bit flags as follows: Bit 0: Set if mouse button is down. Bit 1: Set if Shift is down. Bit 2: Set if Option (*Macintosh*) or Alt (*Windows*) is down. Bit 3: Set if Command (*Macintosh*) or Ctrl (*Windows*) is down. Bit 4: Contextual menu click: right-click or Control-click (*Macintosh*), or right-click (*Windows*). See **Setting Bit Parameters** on page IV-12 for details about bit settings.
`OLDWINDOW`	Previous name of the window or subwindow (for renamed event). Not the old absolute path *hcSpec*, just the name. WINDOW and HCSPEC contain the new name and new *hcSpec*.
`WINDOW`	Name of the window.

The value accompanying the EVENT keyword is one of the following:

eventKey	Meaning
`activate`	Window has just been activated.
`copy`	Copy menu item has been selected.
`cursormoved`	A graph cursor was moved. This event is sent only if bit 2 of the **SetWindow** operation hookevents flag is set.
`deactivate`	Window has just been deactivated.

eventKey	Meaning
enablemenu	Menus are being built and enabled.
hide	Window or subwindows about to be hidden.
hideInfo	The window info box or window has just been hidden by **HideInfo**.
hideTools	The window tool palette or window has just been hidden by **HideTools**.
kill	Window is being killed. Returning a value of 2 as the hook function result prevents Igor from killing the window.
killVote	Window is about to be killed. Return 2 to prevent that, otherwise return 0. See **Window Hook Deactivate, Kill, Show and Hide Events** on page IV-269.
menu	A built-in menu item has been selected.
modified	A modification to the window has been made. This is sent to graph and notebook windows only. It is an error to try to kill a notebook window from the window hook during the modified event.
mousedown	Mouse button was clicked. This event is sent only if bit 0 of the **SetWindow** operation hookevents flag is set.
mousemoved	The mouse moved. This event is sent only if bit 1 of the **SetWindow** operation hookevents flag is set.
mouseup	Mouse button was released. This event is sent only if bit 0 of the **SetWindow** operation hookevents flag is set.
moved	Window has just been moved.
renamed	Window has just been renamed. The previous name is available under the OLDWINDOW key.
resize	Window has just been resized.
show	Window or subwindow is about to be unhidden.
showInfo	The window info box or window has just been shown by **ShowInfo**.
showTools	The window tool palette or window has just been shown by **ShowTools**.
subwindowKill	One of the window's subwindows is about to be killed.

The modified event is issued only when a graph updates (See **DoUpdate**, **PauseUpdate**, and **ResumeUpdate**). Most changes to the graph are reported by the `modified` event, but not all: changing an annotation will not trigger the event, nor will adding, removing, or modifying a control or showing or hiding the drawing tools while using the /A flag. The modified event is not sent while a trace is being dragged or when the values of a trace's wave change (unless one the trace's axes is autoscaled). However, changing an axis range or indeed changing almost anything about axes or showing or hiding the info pane will send the modified event (only one event per graph update). When in doubt, use a print statement to determine when the event is sent.

If mouse events are enabled then the following key:value pairs will also be present in `infoStr`:

Key	Value
MOUSEX	X coordinate in pixels of the mouse.
MOUSEY	Y coordinate in pixels of the mouse.
TICKS	Time event happened.

Note that a mouseup event may or may not correspond to a previous mousedown. If the user clicks in the window, drags out and releases the button then the mouseup event will be missing. If the user clicks in another window, drags into this one and then releases then a mouseup will be sent that had no previous mousedown.

In the case of mousedown or mousemoved messages, a nonzero return value will skip normal processing of the message. This is most useful with mousedown.

The `cursormoved` event is not reported if Option (*Macintosh*) or Alt (*Windows*) is held down.

If the `cursormoved` event is enabled then the following key:value pairs will also be present in `infoStr`:

Key	Value
`CURSOR`	Name of the cursor that moved (A through J).
`TNAME`	Name of the trace the cursor is attached to (invalid if `ISFREE=1`).
`ISFREE`	1 if the cursor is "free" (not attached to a trace), 0 if it is attached to a trace or image.
`POINT`	Point number of the trace if not a free cursor. If the cursor is attached to an image, value is the row number of the image. If a free cursor, value is the fraction of the plot width, 0 being the left edge of the plot area, and 1 being the right edge.
`YPOINT`	Column number if the cursor is attached to an image, NaN if attached to a trace. If a free cursor, value is the fraction of the plot height, 0 being the top edge, and 1 being the bottom edge.

When the a menu event is reported then the following key:value pairs will also be present in `infoStr`:

Key	Value
`MENUNAME`	Name of menu (in English) as used by **SetIgorMenuMode**.
`MENUITEM`	Text of menu item as used by **SetIgorMenuMode**.

The `enablemenu` event does not pass `MENUNAME` or `MENUITEM`.

The `menu` and `enablemenu` messages are not sent when drawing tools are in use in a graph or layout or when waves are being edited in a graph.

Returning a value of 0 for the `enablemenu` message is recommended, though the return value is (currently) ignored.

You can use the **SetIgorMenuMode** operation to alter the enable state of Igor's built-in menus in a way you find appropriate for the window. If you do this, usually you will also handle the menu message and perform your idea of an appropriate action.

Note: Dynamic user-defined menus (see **Dynamic Menu Items** on page IV-109) are built and enabled by using string functions in the menu definitions.

Returning a value of 0 for any menu message allows Igor to perform the normal action. Returning any other value (1 is commonly used) tells Igor to skip performing the normal action.

See the user function description with **IgorMenuHook** on page IV-261 for details on the sequence of menu building, enabling, and handling.

Custom Marker Hook Functions

A custom marker hook function takes one parameter - a WMMarkerHookStruct structure. This structure will provide your function with information you need to draw a marker. See **Structures in Functions** on page IV-78 for background information on structures.

The function prototype used with a custom marker hook has the format:

```
Function MyMarkerHook(s)
   STRUCT WMMarkerHookStruct &s
   <code to draw marker>
   ...
   return statusCode       // 0 if nothing done, else 1
End
```

Your function can use the DrawXXX operations to create the marker. The function is called each time the marker is drawn and should not do anything other than drawing the marker. The function should return 1 if it handled the marker or 0 if not. The marker range can be any positive integers less than 1000 and can overlap built-in marker numbers.

WMMarkerHookStruct

The WMMarkerHookStruct structure has the following members:

WMMarkerHookStruct Structure Members

Member	Description
`Int32 usage`	0= normal draw, 1= legend draw (others reserved).
`Int32 marker`	Marker number minus start (i.e., starts from zero).
`float x,y`	Location of desired center of marker
`float size`	Half width/height of marker
`Int32 opaque`	1 if marker should be opaque
`float penThick`	Stroke width
`STRUCT RGBColor mrkRGB`	Fill color
`STRUCT RGBColor eraseRGB`	Background color
`STRUCT RGBColor penRG`	Stroke color

When your marker function is called, the pen thickness and colors of the drawing environment of the target window are already set consistent with the penThick, mrkRGB, eraseRGB and penRGB members.

Marker Hook Example

Here is an example that draws audiology symbols:

```
Function AudiologyMarkerProc(s)
   STRUCT WMMarkerHookStruct &s

   if( s.marker > 3 )
      return 0
   endif

   Variable size= s.size - s.penThick/2

   if( s.opaque )
      SetDrawEnv linethick=0,fillpat=-1
      DrawRect s.x-size,s.y-size,s.x+size,s.y+size
      SetDrawEnv linethick=s.penThick
   endif
   SetDrawEnv fillpat= 0      // polys are not filled
```

```
    if( s.marker == 0 )        // 90 deg U open to the right
        DrawPoly s.x+size,s.y-size,1,1,{size,-size,-size,-size,-size,size,size,size}
    elseif( s.marker == 1 )    // 90 deg U open to the left
        DrawPoly s.x-size,s.y-size,1,1,{-size,-size,size,-size,size,size,-size,size}
    elseif( s.marker == 2 )    // Cap Gamma
        DrawPoly s.x+size,s.y-size,1,1,{size,-size,-size,-size,-size,size}
    elseif( s.marker == 3 )    // Cap Gamma reversed
        DrawPoly s.x-size,s.y-size,1,1,{-size,-size,size,-size,size,size}
    endif
    return 1
End

Window Graph1() : Graph
    PauseUpdate; Silent 1      // building window...
    Make/O/N=10 testw=sin(x)
    Display /W=(35,44,430,252) testw,testw,testw,testw
    ModifyGraph offset(testw#1)={0,-0.2},offset(testw#2)={0,-0.4},
                offset(testw#3)={0,-0.6}
    ModifyGraph mode=3,marker(testw)=100,marker(testw#1)=101,marker(testw#2)=102,
                marker(testw#3)=103
    SetWindow kwTopWin,markerHook={AudiologyMarkerProc,100,103}
EndMacro
```

Data Acquisition

Igor Pro provides a number of facilities to allow working with live data:

- Live mode traces in graphs
- FIFOs and Charts
- Background task
- External operations and external functions
- Controls and control panels
- User-defined functions

Live mode traces in graphs are useful when you acquiring complete waveforms in a single short operation and you want to update a graph many times per second to create an oscilloscope type display. See **Live Graphs and Oscilloscope Displays** on page II-297 for details.

First-In-First-Out buffers (FIFOs) and Charts are used when you have a continuous stream of data that you want to capture and, perhaps, monitor. See **FIFOs and Charts** on page IV-276 details.

You can set up a background task that will periodically perform data acquisition while allowing you to continue to work with Igor in the foreground. The background operations are *not* done using interrupts and therefore are easily disrupted by foreground operations (that would be you). Background tasks are useful only for relatively infrequent tasks that can be quickly accomplished and do not cause a cascade of graph updates or other things that take a long time. See **Background Tasks** on page IV-279 for details.

You can create an instrument-like front panel for your data acquisition setup using user-defined controls in a panel window. Refer to Chapter III-14, **Controls and Control Panels**, for details. There are many example experiments that can be found in the Examples folder.

Igor Pro comes with an XOP called VDT2 for communicating with instruments via serial port (RS232) and another XOP called NIGPIB2 for communicating via General Purpose Interface Bus (GPIB). See the Igor Pro Folder:More Extensions:Data Acquisition folder.

Sound I/O can be done using the built-in **SoundInRecord** and **PlaySound** operations.

WaveMetrics produces the NIDAQ Tools software package for doing data acquisition using National Instruments cards. NIDAQ Tools is built on top of Igor using all of the techniques mentioned in this section. Information about NIDAQ Tools is available via the WaveMetrics Web site <http://www.wavemetrics.com/Products/NIDAQTools/nidaqtools.htm>.

Third parties have created data acquisition packages that use other hardware. Information about these is also available at <http://www.wavemetrics.com/Products/thirdparty.htm>.

If an XOP package is not available for your hardware you can write your own. For this, you will need to purchase the XOP Toolkit product from WaveMetrics. See **Creating Igor Extensions** on page IV-181 for details.

FIFOs and Charts

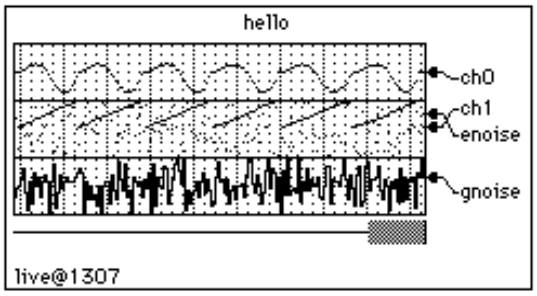
The following information will be of interest principally to people engaged in data acquisition activities. It is possible that there are other uses for these capabilities and you may want to read the following summary to see if you can think of any alternate applications. Most people who use FIFOs and Chart controls will do so via canned packages provided by expert Igor programmers (such as yourself) and will not need to know the details that follow.

Summary

FIFOs are invisible data objects that can act as a First-In-First-Out buffer between a data source and a disk file. Data is placed in a FIFO either via the AddFIFOData operation or via an XOP package designed to interface to a particular piece of hardware. Chart controls provide a graphical view of a portion of the data in a FIFO. When data acquisition is complete a FIFO can operate as a bidirectional buffer to a disk file. This allows the user to review the contents of a file by scrolling the chart "paper" back and forth. FIFOs can be used without a chart but charts have no use without a FIFO to monitor.

FIFOs can have an arbitrary number of channels each with its own number type, scaling info and units. All channels of a given FIFO share a common "timebase". A given chart control can monitor an arbitrary selection of channels from a single FIFO. Each trace can have its own display gain, color and line style and can either have its own area on the "paper" or can share an area with one or more other traces. There can be multiple chart controls active an one time in one or more panel or graph windows.

Here is a typical chart control:



Programming with FIFOs

You can create a FIFO by using the NewFIFO operation. When you are done using a FIFO you use the KillFIFO operation. A freshly created FIFO is not useful until either channels are created with the NewFIFOChan operation or until the FIFO is attached to a disk file for review using a variant of the CtrlFIFO operation. You can obtain information about a FIFO using the FIFOStatus operation and you can extract data from a FIFO using the FIFO2Wave operation. Once a FIFO is set up and ready to accept data, you can insert data using the AddFIFOData operation. Alternately, you can insert data using an XOP package. Once data is stored in a file you can review the data using a FIFO or extract data using user-defined functions. See the example experiment, "FIFO File Parse", for sample utility routines.

As with background tasks, FIFOs are considered transient objects — they are not saved and restored as part of an experiment.

A FIFO does not need to be attached to a file to be useful. Note, however, that the oldest data will be lost when a FIFO overflows.

A FIFO set up to acquire data does not become valid until the start command is issued. Chart controls will report invalid FIFOs on their status line. FIFO2Wave will give an error if it is invoked on an invalid FIFO. A stopped FIFO remains valid until the first command is issued that could potentially change the FIFO's setup.

Data in a running FIFO is written to disk when Igor notices that the FIFO is half full or when the AddFIFOData command is issued and the FIFO is full. The amount of time it takes to write data to disk can be quite considerable and at the same time unpredictable. If the computer disk cache size is large then writes to disk will be less frequent but when they do occur they will take a long time. This will matter to you most if you are attempting to take data rapidly using software (perhaps using an Igor background task). If you are taking data via interrupt transfer to an intermediate buffer of adequate size or if your hardware has an adequate internal buffer then the disk write latency may not be a concern. If dead time due to disk writes is a concern then you may want to decrease the size of the disk cache and you may want to run with a relatively small FIFO. Note that if you change the size of the disk cache you may have to reboot for the change to take effect.

When the stop command is given to a running FIFO then it goes into review mode and remains valid. If the FIFO is attached to a file then the entire contents of the file can be reviewed or be transferred to a wave using the FIFO2Wave command.

The act of attaching a FIFO to an existing file for review using the rfile keyword of the CtrlFIFO command reads in the file contents and sets itself up for review. You should not use the NewFIFOChan command or any of the other CtrlFIFO keywords except size. Here is all that is required to review a preexisting file:

```
Variable refnum
Open/R/P=mypath refnum as "my file"
NewFIFO dave
CtrlFIFO dave,rfile=refnum
```

If any chart controls have been set up to monitor FIFO dave then they will automatically configure themselves to display all the channels of dave using default parameters.

The connection between FIFOs and chart controls relies on Igor's dependency manager. The dependency manager does not automatically run during function execution — you have to explicitly call it by executing the DoUpdate command.

The dependency manager sends messages to a chart control when:

- a FIFO is created
- a FIFO is killed
- a FIFO becomes valid (start command)
- data is added to a FIFO

In particular, if inside a user function, you kill a FIFO and then create it again you should call DoUpdate after the kill so that the chart control notices the kill and can get ready for the creation.

FIFO File Format

This information is for users who may wish to create FIFO files with their own programs or for those who need to analyze data stored in a FIFO file. You will need to have a reading familiarity with the C programming language to understand the following. Note, the following information may be out of date. For the most up to date information, refer to the most recent version of the auxiliary file named NamedFIFO.h located in the "Miscellaneous:More Documentation:" folder.

Consider the following data structures….

```
#define CUR_FIFOFILE_VERSION 0

typedef struct FIFOFIleHeader{
   long typeP1,typeP2;        // 'IGOR','fifo'
   long version;              // CUR_FIFOFILE_VERSION
   long datasize; // bytes of data following ChartChunkInfo field if known
   long hsize;    // size of following ChartChunkInfo field; data follows
}FIFOFIleHeader;
```

```
#define MAX_NOTESIZE 255
#define FIFO_CHAN_VERSION_NUM 0x01

typedef struct ChartChanInfo{
   long ntype;          // number type -- NT_FP32 or NT_I16 or ...
   double offset,gain;        // result= (measval-offset)*gain
   double fsPlus,fsMinus;     // value of + & - full scale
   char name[MAX_OBJ_NAME+1]; // name of this channel
   char units[4];             // SU abbrev of units
   long chanRefcon;           // for use by data acquisition sw
}ChartChanInfo;

typedef struct ChartChunkInfo{
   long type;              // 'chrt'
   short version;          // version number of this data structure
   short pad1;             // maintain 32 bit allignment
   unsigned long startDate;   // datetime of start command
   char note[MAX_NOTESIZE+1];    // room for a short note from user
   double deltaT;    // data acquisition speed (if known,in seconds)
   long xopRefcon;               // for use by data acquisition sw
   long nchan;                   // number of channels
   ChartChanInfo info[];         // info for each channel
}ChartChunkInfo;
```

The FIFO file consists of the FIFOFileHeader followed by the ChartChunkInfo and finally by chunks of data until the end of the file. It is expected that the format of this file will undergo evolutionary changes. You should be prepared to keep up with such changes. In particular you should always check for the proper version numbers when trying to interpret such a file.

Charts

An Igor Chart works in conjunction with a FIFO to display data as it is acquired or to review data that has previously been acquired.

The information provided here pertains to using rather than programming a chart. If you are interested in programming a chart application, you should examine the examples provided by WaveMetrics in the Examples folder.

Chart Basics

An Igor Chart is neither an analytical tool nor a presentation quality graphic. It is meant only for real time monitoring of incoming data or to review data from a FIFO file. When you want an analytical or presentation quality graph you must transfer the data to a wave and then use a conventional Igor graph.

An Igor Chart emulates a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. It differs from a real chart recorder in that the paper of the latter moves at a constant velocity whereas the "paper" of an Igor chart moves only when data becomes available in the FIFO it is monitoring. If data is placed in the FIFO at a constant rate then the "paper" will scroll by at a constant rate. However, since there can be no guarantee that the data is coming in at a constant rate, we refer to the horizontal axis not in terms of time but rather in terms of data sample number.

A given chart can monitor an arbitrary selection of channels from a single FIFO. Each chart trace can have its own display gain, color and line style and can either have its own area on the "paper" or can share an area with one or more other traces. There can be multiple charts active an one time in one or more control panel or graph windows.

You create a chart using the **Chart** operation (page V-43). You can obtain information about a given chart using the **ControlInfo** operation (page V-63).

Additional Notes

Charts sometimes try to auto-configure themselves to match their FIFO. Generally this action is exactly what you want and is unobtrusive. Here are the rules that charts use:

When the FIFO becomes invalid or if it ceases to exist then the chart marks itself as being in auto-configure mode. If the FIFO then becomes valid the chart will read the FIFO information and configure itself to monitor all channels. It tries to set the ppStrip parameter to a value appropriate for the deltaT value of the FIFO. It does so by assuming a desirable update rate of around 10 strips per second. Thus, for example, if deltaT was 1 millisecond then ppStrip would be set to 100. The moral is: deltaT had better be valid or weird values of ppStrip may be created.

Any chart channel configuration commands executed after the FIFO becomes invalid but before the FIFO becomes valid again will prevent auto-configuration from taking place.

Background Tasks

Background tasks allow procedures to run periodically "in the background" while you continue to interact normally with Igor. This is useful for data acquisition, simulations and other processes that run indefinitely, over long periods of time, or need to run at regular intervals. Using a background task allows you to continue to interact with Igor while your data acquisition or simulation runs.

Originally Igor supported just one unnamed background task controlled using the **CtrlBackground** operation (page V-81). New code should use the **CtrlNamedBackground** operation (page V-82) to create named background tasks instead, as shown in the following sections. You can run any number of named backgrounds tasks.

In addition to the documentation provided here, the Background Task Demo experiment provides sample code that is designed to be redeployed for other projects. We recommend reading this documentation first and then opening the demo by choosing File→Example Experiments→Programming→Background Task Demo.

Background Task Example #1

You create and control background tasks using the **CtrlNamedBackground** operation. The main parameters of CtrlNamedBackground are the background task name, the name of a procedure to be called periodically, and the period. Here is a simple example:

```
Function TestTask(s)    // This is the function that will be called periodically
   STRUCT WMBackgroundStruct &s

   Printf "Task %s called, ticks=%d\r", s.name, s.curRunTicks
   return 0             // Continue background task
End

Function StartTestTask()
   Variable numTicks = 2 * 60    // Run every two seconds (120 ticks)
   CtrlNamedBackground Test, period=numTicks, proc=TestTask
   CtrlNamedBackground Test, start
End

Function StopTestTask()
   CtrlNamedBackground Test, stop
End
```

You start this background task by calling StartTestTask from the command line or from another procedure. StartTestTask creates a background task named Test, sets the period which is specified in units of ticks (1 tick = 1/60th of a second), and specifies the user-defined function to be called periodically (TestTask in this example).

You stop the Test background task by calling StopTestTask.

As shown above, the background procedure takes a **WMBackgroundStruct** parameter. In most cases you won't need to access it.

Background Task Exit Code

The background procedure (TestTask in the example above) returns an exit code to Igor. The code is one of the following values:

0: The background procedure executed normally.

1: The background procedure wants to stop the background task.

2: The background procedure encountered an error and wants to stop the background task.

Normally the background procedure should return 0 and the background task will continue to run. If you return a non-zero value, Igor stops the background task. You can tell Igor to terminate the background task by returning the value 1 from the background function.

If you forget to add a return statement to your background procedure, this acts like a non-zero return value and stops the background task.

Background Task Period

The CtrlNamedBackground operation's period keyword takes an integer parameter expressed in ticks. A tick is approximately 1/60th of a second. Thus the timing of Igor background tasks has a nominal resolution of 1/60th of a second.

You can override the specified period in the background task procedure by writing to the nextRunTicks field of the **WMBackgroundStruct** structure. This is needed only if you want your procedure to run at irregular intervals.

The actual time between calls to the background procedure is not guaranteed. Igor runs the background task from its outer loop, when Igor is doing nothing else. If you do something in Igor that takes a long time, for example performing a lengthy curve fit, running a user-defined function that takes a long time, or saving a large experiment, Igor's outer loop does not run so the background task will not run. If you do something that causes a compilation of Igor procedures to fail, the background task is not called. On Macintosh, the background task is not called while a menu is displayed or while the mouse button is pressed.

If you need your background task to continue running even if you edit other procedures in Igor, you need to make your project an independent module. See **Independent Modules** on page IV-214 for details.

If you need precise timing that can not be interrupted, things get much more complicated. You need to do your data acquisition in an Igor thread running in an independent module or in a thread created by an XOP that you write. See **ThreadSafe Functions and Multitasking** on page IV-288 for details.

The shortest supported period is one tick. The minimum actual period for the background task depends on your hardware and what your background task is doing. If you set the period too low for your background task, interacting with Igor becomes sluggish.

It is very easy to bog your computer down using background tasks. If the background task takes a long time to execute or if it triggers something that takes a long time (like a wave dependency formula or updating a complex graph) then it may appear that the system is hung. It is not, but it may take longer to respond to user actions than you are willing to wait.

Background Task Limitations

The principal limitation of Igor background tasks is that they are stopped while other operations are taking place. Thus, although you can type commands into the command line without disrupting the background task, when you press Return the task is stopped until execution of the command line is finished.

Background tasks do not run if procedures are in an uncompiled state. If you need your background task to continue running even if you edit other procedures in Igor, you need to make your project an independent module. See **Independent Modules** on page IV-214 for details.

On Macintosh, the background task does not run when the mouse button is pressed or when a menu is displayed.

Background Tasks and Errors

If a background task procedure contains a bug, it will typically generate an error each time the procedure runs. Normally an error generates an error dialog. If this happened over and over again, it would prevent you from fixing the bug.

Igor handles such repeated errors as follows: The first time an error occurs during the execution of the background task procedure, Igor displays an error dialog. On subsequent errors, Igor prints an error message in the history. After printing 10 such error messages, Igor stops printing messages. When you click a control, execute a command from the command line or execute a command through a menu item, the process starts over.

If the Igor debugger is enabled and Debug on Error is turned on, Igor will break into the debugger each time an error occurs in the background task procedure. You may have to turn Debug on Error off to give you time to stop the background task. You can do this from within the debugger by right-clicking.

Background Tasks and Dialogs

By default, a background task created by CtrlNamedBackground continues to run while a dialog is displayed. You can change this behavior using the CtrlNamedBackground dialogsOK keyword.

If you allow background tasks to run while an Igor dialog is present, you should ensure that your background task does not kill anything that a dialog might depend on. It should not kill waves or variables. It should never directly modify a window (except for a status panel) and especially should never remove something from a window (such as a trace from a graph). Otherwise your background task may kill something that the dialog depends on which will cause a crash.

Background Task Tips

Background tasks should be designed to execute quickly. They do not run in separate threads threads and they hang Igor's event processing as long as they run. For maximum responsiveness, your task procedure should take no more than a fraction of a second to run even when the period is long. If you have to perform a lengthy computation, let the user know what is going on, perhaps via a message in a status control panel.

Background tasks should never attempt to put up dialogs or directly wait for user input. If you need to get the attention of the user, you should design your system to include a status control panel with an area for messages or some other change in appearance. If you need to wait for the user, you should do so by monitoring global variables set by nonbackground code such as a button procedure in a panel.

Your task procedure should always leave the current data folder unchanged on exit.

Background Task Example #2

Here is an example that uses many of the concepts discussed above. The task prints a message in the history area at one second intervals five times, performs a "lengthy calculation", and then waits for the user to give the go-ahead for another run.

The task does its own timing and consequently is set to run at the maximum rate (60 times per second). The task procedure, MyBGTask, tests to see if one second has elapsed since the last time it printed a message. In a real application, you might test to see if some external event has occurred.

To try the example, copy the code below to the Procedure window and execute:

```
BGDemo()
```

```
Function BGDemo()
   DoWindow/F BGDemoPanel        // bring panel to front if it exists
   if( V_Flag != 0 )
      return 0                   // panel already exists
   endif

   String dfSav= GetDataFolder(1)// so we can leave current DF as we found it
   NewDataFolder/O/S root:Packages
   NewDataFolder/O/S root:Packages:MyDemo  // our variables go here

   // still here if no panel, create globals if needed
   if( NumVarOrDefault("inited",0) == 0 )
      Variable/G inited= 1

      Variable/G lastRunTicks= 0 // value of ticks function last time we ran
      Variable/G runNumber= 0             // incremented each time we run
      // message displayed in panel using SetVariable...
      String/G message="Task paused. Click Start to resume."

      Variable/G running=0                // when set, we do our thing
   endif

   SetDataFolder dfSav
   NewPanel /W=(150,50,449,163)
   DoWindow/C BGDemoPanel                 // set panel name
   Button StartButton,pos={21,12},size={50,20},proc=BGStartStopProc,title="Start"
   SetVariable msg,pos={21,43},size={300,17},title=" ",frame=0
   SetVariable msg,limits={-Inf,Inf,1},value= root:Packages:MyDemo:message
End

Function MyBGTask(s)
   STRUCT WMBackgroundStruct &s

   NVAR running= root:Packages:MyDemo:running

   if( running == 0 )
      return 0                     // not running -- wait for user
   endif

   NVAR lastRunTicks= root:Packages:MyDemo:lastRunTicks

   if( (lastRunTicks+60) >= ticks )
      return 0                     // not time yet, wait
   endif

   NVAR runNumber= root:Packages:MyDemo:runNumber

   runNumber += 1

   printf "Hello from the background, #%d\r",runNumber

   if( runNumber >= 5 )
      runNumber= 0
      running= 0                   // turn ourself off after five runs

      // run again when user says to
      Button StopButton,win=BGDemoPanel,rename=StartButton,title="Start"

      // Simulate a long calculation after a run
      String/G root:Packages:MyDemo:message="Performing long calculation. Please wait."
      ControlUpdate /W=BGDemoPanel msg
      DoUpdate /W=BGDemoPanel      // Required on Macintosh for control to be redrawn

      Variable t0= ticks
      do
         if (GetKeyState(0) & 32)
            Print "Lengthy process aborted by Escape key"
            break
         endif
      while( ticks < (t0+60*3) )    // delay for 3 seconds

      String/G root:Packages:MyDemo:message="Task paused. Click Start to resume."
   endif

   lastRunTicks= ticks

   return 0
End
```

```
Function BGStartStopProc(ctrlName) : ButtonControl
    String ctrlName

    NVAR running= root:Packages:MyDemo:running
    if( CmpStr(ctrlName,"StartButton") == 0 )
        running= 1
        Button $ctrlName,rename=StopButton,title="Stop"
        String/G root:Packages:MyDemo:message=""
        CtrlNamedBackground MyBGTask, proc=MyBGTask, period=1, start
    endif
    if( CmpStr(ctrlName,"StopButton") == 0 )
        running= 0
        Button $ctrlName,rename=StartButton,title="Start"
        CtrlNamedBackground MyBGTask, stop
        String/G root:Packages:MyDemo:message="Task paused. Press Start to resume."
    endif
End
```

Background Task Example #3

For another example including code that you can easily redeploy for your own project, see the Background Task Demo experiment (choose File→Example Experiments→Programming→Background Task Demo).

Old Background Task Techniques

Originally Igor supported just one unnamed background task. This is still supported for backward compatibility but new code should use CtrlNamedBackground to create and control named background tasks instead.

The unnamed background task is designated using **SetBackground**, controlled using **CtrlBackground** and killed using **KillBackground**. The **BackgroundInfo** operation returns information about the unnamed background task.

The SetBackground, CtrlBackground, KillBackground and BackgroundInfo operations work only with the unnamed background task. For named background tasks, the CtrlNamedBackground operation provides all necessary functionality.

By default, a background task created by CtrlBackground does not run while a dialog is displayed. You can change this behavior using the CtrlBackground dialogsOK keyword.

Automatic Parallel Processing with MultiThread

In Igor Pro 6.1 or later, intermediate level Igor programmers can make use of multiple processors to speed up wave assignment statements in user-defined functions. To do this, simply insert the keyword MultiThread in front of a normal wave assignment. For example, in a function:

```
Make wave1
Variable a=4
MultiThread wave1= sin(x/a)
```

The expression, on the righthand side of the assignment statement, is compiled as ThreadSafe even if the host function is not.

Note: Because of the overhead of spawning threads, you should use MultiThread only when the destination has a large number of points or the expression takes a significant amount of time to evaluate. Otherwise, you may see a performance penalty rather than an improvement.

The assignment is automatically parceled into as many threads as there are processors, each evaluating the righthand expression for a different output point.

The MultiThread keyword causes Igor to evaluate the expression for multiple output points simultaneously. Do not make any assumptions as to the order of processing and certainly do not try to use a point from the destination wave other than the current point in the expression. For example, do not do something like this:

```
wave1= wave1[p+1] - wave1[p-1]   // Result will be indeterminate
```

Expressions like that can give indeterminate results even in the absence of threading.

Here is a simple example to try on your own machine:

```
Function TestMultiThread(n)
   Variable n                    // Number of wave points

   Make/O/N=(n) testWave

   // To prime processor data cache so comparison will be valid
   testWave= 0

   Variable t1,t2
   Variable timerRefNum

   // First, non-threaded
   timerRefNum = StartMSTimer
   testWave= sin(x/8)
   t1= StopMSTimer(timerRefNum)

   // Now, automatically threaded
   timerRefNum = StartMSTimer
   MultiThread testWave= sin(x/8)
   t2= StopMSTimer(timerRefNum)

   Variable processors = ThreadProcessorCount
   Print "On a machine with",processors,"cores,MultiThread is", t1/t2,"faster"
End
```

Here is the output on a Mac Pro:

```
•TestMultiThread(100)
  On a machine with  8  cores, MultiThread is  0.059746  faster

•TestMultiThread(10000)
  On a machine with  8  cores, MultiThread is  3.4779  faster

•TestMultiThread(1000000)
  On a machine with  8  cores, MultiThread is  6.72999  faster

•TestMultiThread(10000000)
  On a machine with  8  cores, MultiThread is  8.11069  faster
```

The first result shows that the MultiThread keyword slowed the assignment down. This is because the assignment involved a small number of points and MultiThread has some overhead.

The remaining results illustrate that MultiThread can provide increased speed for assignments involving large waves.

In the last result, the speed improvement factor was greater than the number of processors. This is explained by the fact that, once running, a ThreadSafe expression has slightly less overhead than a normal expression.

If the right hand side involves calling user-defined functions, those functions must be ThreadSafe (see **ThreadSafe Functions** on page IV-83) and must also follow these rules:

1. Do not do anything to waves that are passed as parameters that might disturb memory. For example, do not change the number of points in the wave or change its data type or kill it or write to a text wave.
2. Do not write to a variable that is passed by reference.

3. Note that any waves or global variables created by the function will disappear when then wave assignment is finished.

Failure to heed rule #1 will likely result in a crash.

Although it is legal to use the MultiThread mechanism in a ThreadSafe function that is already running in a preemptive thread via **ThreadStart**, it is not recommended and will likely result in a substantial loss of speed.

For an example using MultiThread, open the Mandelbrot demo experiment file by choosing "File→Example Experiments→Programming→MultiThreadMandelbrot".

Data Folder Reference MultiThread Example

Advanced programmers can use waves containing data folder references and wave references along with MultiThread to perform multithreaded calculations more involved than evaluating an arithmetic expression. Here we use **Free Data Folders** (see page IV-75) to facilitate multithreading.

In this example, we extract each of the planes of a 3D wave, perform a filtering operation on the planes, and then finally assemble the planes into an output 3D wave. The main function, Test, executes a multithreaded assignment statement where the expression includes a call to a subroutine named Worker.

Because MultiThread is used, multiple instances of Worker execute simultaneously on different cores. Each instance runs in its own thread, working on a different plane. Each instance returns one filtered plane in a wave named M_ImagePlane in a thread-specific free data folder. The use of free data folders allows each instance of Worker to work on its own M_ImagePlane wave without creating a name conflict.

When the multithreaded assignment is finished, the main function assembles an output 3D wave by concatenating the filtered planes.

```
// Extracts a plane from the 3D input wave, filters it, and returns the
// filtered output as M_ImagePlane in a new free data folder
ThreadSafe Function/DF Worker(w3DIn, plane)
   WAVE w3DIn
   Variable plane

   DFREF dfSav= GetDataFolderDFR()

   // Create a free data folder to hold the extracted and filtered plane
   DFREF dfFree= NewFreeDataFolder()
   SetDataFolder dfFree

   // Extract the plane from the input wave into M_ImagePlane.
   // M_ImagePlane is created in the current data folder
   // which is a free data folder.
   ImageTransform/P=(plane) getPlane, w3DIn

   // Filter the plane
   WAVE wOut= M_ImagePlane
   MatrixFilter/N=21 gauss,wOut

   SetDataFolder dfSav

   // Return a reference to the free data folder containing M_ImagePlane
   return dfFree
End

Function Test()
   Variable numPlanes = 50

   // Create a 3D wave and fill it with data
   Make/O/N=(200,200,numPlanes) src3D= (p==(2*r))*(q==(2*r))
```

```
   // Create a wave to hold data folder references returned by Worker.
   // /DF specifies the data type of the wave as "data folder reference".
   Make/DF/N=(numPlanes) dfw

   Variable timerRefNum = StartMSTimer

   MultiThread dfw= Worker(src3D,p)

   Variable elapsedTime = StopMSTimer(timerRefNum) / 1E6

   Print "Assignment statement took ", elapsedTime, " seconds"

   // At this point, dfw holds data folder references to 50 free
   // data folders created by Worker. Each free data folder holds the
   // extracted and filtered data for one plane of the source 3D wave.

   // Create an output wave named out3D by cloning the first filtered plane
   DFREF df= dfw[0]
   Duplicate/O df:M_ImagePlane, out3D

   // Concatenate the remaining filtered planes onto out3D
   Variable i
   for(i=1; i<numPlanes; i+=1)
      df= dfw[i]     // Get a reference to the next free data folder
      Concatenate {df:M_ImagePlane}, out3D
   endfor

   // dfw holds references to the free data folders. By killing dfw,
   // we kill the last reference to the free data folders which causes
   // them to be automatically deleted. Because there are no remaining
   // references to the various M_ImagePlane waves, they too are
   // automatically deleted.
   KillWaves dfw
End
```

On an eight-core Mac Pro, without the MultiThread keyword above, Test printed:

```
  Assignment statement took   4.16909   seconds
```

and with MultiThread:

```
  Assignment statement took   0.614999   seconds
```

for a speed up of about 6.8 times.

Wave Reference MultiThread Example

In the preceding example, free data folders were used to hold data processed by threads. Since each free data folder held just a single wave, the example can be simplified by using free waves instead of free data folders. So here we perform the same threaded filtering of planes using free waves.

Because MultiThread is used, multiple instances of Worker execute simultaneously on different cores. Each instance runs in its own thread, working on a different plane. Each instance returns one filtered plane in a free wave named M_ImagePlane. The use of free waves allows each instance of Worker to work on its own M_ImagePlane wave without creating a name conflict.

This version of the example relies on the fact that a wave in a free data folder becomes a free wave when the free data folder is automatically deleted. See **Free Wave Lifetime** on page IV-73 for details.

```
ThreadSafe Function/WAVE Worker(w3DIn, plane)
   WAVE w3DIn
```

```
   Variable plane

   DFREF dfSav= GetDataFolderDFR()

   // Create a free data folder and set it as the current data folder
   SetDataFolder NewFreeDataFolder()

   // Extract the plane from the input wave into M_ImagePlane.
   // M_ImagePlane is created in the current data folder
   // which is a free data folder.
   ImageTransform/P=(plane) getPlane, w3DIn

   // Filter the plane
   WAVE wOut= M_ImagePlane
   MatrixFilter/N=21 gauss,wOut

   // Restore the current data folder
   SetDataFolder dfSav

   // Since the only reference to the free data folder created above
   // was the current data folder, there are now no references it.
   // Therefore, Igor has automatically deleted it.
   // Since there IS a reference to the M_ImagePlane wave in the free
   // data folder, M_ImagePlane is not deleted but becomes a free wave.

   return wOut       // Return a reference to the free M_ImagePlane wave
End

Function Test()
   Variable numPlanes = 50

   // Create a 3D wave and fill it with data
   Make/O/N=(200,200,numPlanes) srcData= (p==(2*r))*(q==(2*r))

   // Create a wave to hold data folder references returned by Worker.
   // /WAVE specifies the data type of the wave as "wave reference".
   Make/WAVE/N=(numPlanes) ww

   Variable timerRefNum = StartMSTimer

   MultiThread ww= Worker(srcData,p)

   Variable elapsedTime = StopMSTimer(timerRefNum) / 1E6

   Print "Assignment statement took ", elapsedTime, " seconds"

   // At this point, ww holds wave references to 50 M_ImagePlane free waves
   // created by Worker. Each M_ImagePlane holds the extracted and filtered
   // data for one plane of the source 3D wave.

   // Create an output wave named out3D by cloning the first filtered plane
   WAVE w= ww[0]
   Duplicate/O w, out3D

   // Concatenate the remaining filtered planes onto out3D
   Variable i
   for(i=1;i<numPlanes;i+=1)
      WAVE w= ww[i]
      Concatenate {w}, out3D
   endfor
```

```
   // ww holds references to the free waves. By killing ww, we kill
   // the last reference to the free waves which causes them to be
   // automatically deleted.
   KillWaves ww
End
```

ThreadSafe Functions and Multitasking

Experienced programmers can use **ThreadSafe Functions** (see page IV-83) to improve execution speed on computers with multiple processors and to create preemptive multitasking background tasks.

In Igor Pro 6.10 or later, a much simpler method that can be used by intermediate level programmers is available - see **Automatic Parallel Processing with MultiThread** on page IV-283. But to write a complex multitasking application, you need to use the techniques described in this section.

Preemptive multitasking uses the following functions and operations:

ThreadGroupCreate	**ThreadGroupWait**
ThreadGroupGetDF	**ThreadProcessorCount**
ThreadGroupPutDF	**ThreadReturnValue**
ThreadGroupRelease	**ThreadStart**

To run a ThreadSafe function preemptively, you first create a thread group using **ThreadGroupCreate** and then call **ThreadStart** to start your worker function. Usually you will use the same function for each thread of a group although they can be different.

The worker function must be defined as ThreadSafe and must return a real or complex numeric result. The return value can be obtained after the function finishes by calling **ThreadReturnValue**.

The worker function can take variable and wave parameters. It can not take pass-by-reference parameters or data folder reference parameters.

Any waves you pass to the worker are accessible to both the main thread and to your preemptive thread. Such waves are marked as being in use by a thread and Igor will refuse to perform any manipulations that could change the size of the wave.

You can determine if any threads of a group are still running by calling **ThreadGroupWait**. Use zero for milliseconds to wait to just test or provide a large value to cause the main thread to sleep until the threads are finished. If you know the maximum time the threads should take, you can use that value so you can print an error message or take other action if the threads don't return in time.

Once you are finished with a given thread group, call **ThreadGroupRelease**.

The Igor Debugger can not be used with preemptive threads. You will need to use print statements for debugging.

The hard part of using multithreading is devising a scheme for partitioning your data processing algorithms into threads.

Thread Data Environment

When a thread is started, Igor creates a root data folder for that thread. This root data folder and any data objects that the thread creates in it are private to the thread. This constitutes a separate data hierarchy for each thread.

Data is transferred, when you request it, from the main thread to a preemptive thread and vice-versa using input and output queues. The "currency" of these queues is the data folder, which provides considerable flexibility for passing data to threads and for retrieving results. Each thread group has an input queue to

which the main thread may post data and an output queue from which the main thread may retrieve results.

The terms “input“ and “output“ are relative to the preemptive thread. The main thread posts a data folder to the input queue to send input to the preemptive thread. The preemptive thread retrieves the data folder from the input queue. After processing, the preemptive thread may post a data folder to the output queue. The main thread reads output from the preemptive thread by retrieving the data folder from the output queue.

Use **ThreadGroupPutDF** to post data folders and **ThreadGroupGetDF** to retrieve them. These are called from both the main thread and from preemptive threads.

ThreadGroupPutDF clips the specified data folder (and everything it contains) out of the source thread and puts it in the queue. From the standpoint of the source thread, it is as if KillDataFolder had been called. While a data folder resides in a queue, it is not accessible by any thread. See the documentation for **ThreadGroupPutDF** for some warnings about its use.

ThreadGroupGetDF stitches the data folder from the queue into the current data folder of the calling thread and gives it a unique name starting with its original name. It is then owned by the calling thread.

Parallel Processing

In this example, we attempt to improve the speed of filling columns of a 2D wave with a sin function. The traditional method is compared with parallel processing. Notice how much more complicated the multi-threaded version, MTFillWave, is compared to the single threaded STFillWave.

```
ThreadSafe Function MyWorkerFunc(w,col)
    WAVE w
    Variable col

    w[][col]= sin(x/(col+1))

    return stopMSTimer(-2)            // Time when we finished
End

Function MTFillWave(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable i,col,nthreads= ThreadProcessorCount
    variable mt= ThreadGroupCreate(nthreads)

    for(col= 0;col<ncol;)
        for(i=0;i<nthreads;i+=1)
            ThreadStart mt,i,MyWorkerFunc(dest,col)
            col+=1
            if( col>=ncol )
                break
            endif
        endfor

        do
            variable tgs= ThreadGroupWait(mt,100)
        while( tgs != 0 )
    endfor
    variable dummy= ThreadGroupRelease(mt)
End

Function STFillWave(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable col

    for(col= 0;col<ncol;col+=1)
        MyWorkerFunc(dest,col)
    endfor
End

Function ThreadTest(rows)
    Variable rows
```

```
    Variable cols=10

    make/o/n=(rows,cols) jack

    Variable i

    for(i=0;i<10;i+=1)      // get any pending pause events out of the way
    endfor

    Variable ttime= stopMSTimer(-2)

    Variable t0= stopMSTimer(-2)
    MTFillWave(jack)
    Variable t1= stopMSTimer(-2)
    STFillWave(jack)
    Variable t2= stopMSTimer(-2)

    ttime= (stopMSTimer(-2) - ttime)*1e-6

    // Times are in microseconds
    printf "ST: %d, MT: %d; ",t2-t1,t1-t0
    printf "speed up factor: %.3g; tot time= %.3gs\r",(t2-t1)/(t1-t0),ttime
End
```

The empty loop above is necessary because of periodic pauses in execution to check for user aborts. If a pause was pending, we want to get it out of the way beforehand to avoid it affecting the first timing test.

After starting Igor Pro, there is initially some extra overhead associated with creating new threads. Consequently, in the test results to follow, the first test is run twice.

Results for Mac Mini 1.66 GHz Core Duo, OS X 10.4.6:

```
•ThreadTest(100)
  ST: 223, MT: 1192; speed up factor: 0.187; tot time= 0.00146s
•ThreadTest(100)
  ST: 211, MT: 884; speed up factor: 0.239; tot time= 0.0011s
•ThreadTest(1000)
  ST: 1991, MT: 1821; speed up factor: 1.09; tot time= 0.00381s
•ThreadTest(10000)
  ST: 19857, MT: 11921; speed up factor: 1.67; tot time= 0.0318s
•ThreadTest(100000)
  ST: 199174, MT: 113701; speed up factor: 1.75; tot time= 0.313s
•ThreadTest(1000000)
  ST: 2009948, MT: 1146113; speed up factor: 1.75; tot time= 3.16s
```

As you can see, when there is sufficient work to be done, the speed up factor approaches the theoretical maximum of 2 for dual processors.

Now on the same computer but booting into Windows XP Pro:

```
•ThreadTest(100)
  ST: 245, MT: 523; speed up factor: 0.468; tot time= 0.000776s
•ThreadTest(100)
  ST: 399, MT: 247; speed up factor: 1.61; tot time= 0.000655s
•ThreadTest(1000)
  ST: 3526, MT: 1148; speed up factor: 3.07; tot time= 0.00468s
•ThreadTest(10000)
  ST: 34830, MT: 10467; speed up factor: 3.33; tot time= 0.0453s
•ThreadTest(100000)
  ST: 350253, MT: 99298; speed up factor: 3.53; tot time= 0.45s
•ThreadTest(1000000)
  ST: 2837645, MT: 1057275; speed up factor: 2.68; tot time= 3.89s
```

So, what is happening here? The speed-up factors for Windows XP are greater than for Mac OS X, but mostly because the ST version is much slower. We do not known why the ST version runs more slowly — the Benchmark 2.01 example experiment shows similar values for OS X vs. XP on this same computer.

Input/Output Queues

In this example, we create data folders containing a data wave and a string variable, which specifies the task to be performed, and then post them to a thread group. We use a different data folder for output although you can also simply reuse the input data folder.

```
ThreadSafe Function MyWorkerFunc()
```

```
    do
        do
            String tdf= ThreadGroupGetDF(0,1000)
            if( strlen(tdf) == 0 )
                if( GetRTError(2) ) // New in 6.20 to allow this distinction:
                    Print "worker closing down due to group release"
                else
                    Print "worker thread still waiting for input queue"
                endif
            else
                break
            endif
        while(1)

        SetDataFolder tdf
        SVAR todo
        WAVE jack

        // To reuse the input data folder, simply remove the next two
        // statments as well as the KillDataFolder below.
        SetDataFolder ::

        NewDataFolder/S outDF

        Duplicate jack,outw // WARNING: outw must be cleared. See WAVEClear below
        String/G did= todo
        if( CmpStr(todo,"sin") )
            outw= sin(outw)
        else
            outw= cos(outw)
        endif

        // Needed if you change the code to reuse input data folder. Allows put.
        WAVEClear jack

        // Clear outw so Duplicate above does not try to use it and to allow put.
        WAVEClear outw

        ThreadGroupPutDF 0,:

        KillDataFolder tdf      // We are done with the input data folder
    while(1)

    return 0
End

Function TestThreadQueue()
    Variable i,ntries= 5,nthreads= 2

    variable/G tgID= ThreadGroupCreate(nthreads)

    for(i=0;i<nthreads;i+=1)
        ThreadStart tgID,i,MyWorkerFunc()
    endfor

    for(i=0;i<ntries;i+=1)
        NewDataFolder/S forThread
        String/G todo
        if( mod(i,3) == 0 )
            todo= "sin"
        else
            todo= "cos"
        endif
        Make/N= 5 jack= x + gnoise(0.1)

        WAVEClear jack

        ThreadGroupPutDF tgID,:
    endfor

    for(i=0;i<ntries;i+=1)
        do
            DFREF dfr= ThreadGroupGetDFR(tgID,1000) // Get results in free data folder
```

```
         if ( DatafolderRefStatus(dfr) == 0 )
            Print "Main still waiting for worker thread results."
         else
            break
         endif
      while(1)

      SVAR/SDFR=dfr did
      WAVE/SDFR=dfr outw

      Print "task= ",did,"results= ",outw

      // The next two statements are not really needed as the same action
      // will happen the next time through the loop or, for the last iteration,
      // when this function returns.
      WAVEClear outw
      KillDataFolder dfr
   endfor

   // This terminates the MyWorkerFunc by setting an abort flag
   Variable tstatus= ThreadGroupRelease(tgID)
   if( tstatus == -2 )
      Print "Thread would not quit normally, had to force kill it. Restart Igor."
   endif
End
```

Typical output:

```
•TestThreadQueue()
   task=   sin  results=
outw[0]= {0.994567,0.660904,-0.516692,-0.996884,-0.63106}
   task=   cos  results=
outw[0]= {0.0786631,0.709576,0.873524,0.0586175,-0.718122}
   task=   cos  results=
outw[0]= {-0.23686,0.848603,0.871922,0.0992451,-0.856209}
   task=   sin  results=
outw[0]= {0.999734,0.531563,-0.172071,-0.931296,-0.750942}
   task=   cos  results=
outw[0]= {-0.166893,0.767707,0.925874,0.114511,-0.662994}
   worker closing down due to group release
   worker closing down due to group release
```

Preemptive Background Task

In this example, we create a single worker thread that runs while the user can do other things. A normal cooperative named background task will retrieve results. Although the named task will sometimes be blocked (as described in **Background Tasks** on page IV-279) the preemptive worker thread will always be running or waiting for data.

We put the code for the background tasks in an independent module (see **The IndependentModule Pragma** on page IV-43) so that the user can recompile procedures, which is done automatically when a recreation macro is created.

One use for a preemptive background task is when you have lengthy computations but want to continue to do other things, such as creating graphics for publication. Although you can do anything you want while the task runs in the experiment, if you load a different experiment, the thread will be killed.

Our "lengthy computation" is simply creating a wave of sin values but which is prolonged by code delays of a few seconds before posting the results. The named background task checks the output queue every 10 ticks (when it is not blocked) and updates a graph with data retrieved from the queue.

Copy the following code to a new procedure window (not the main procedure window):

```
#pragma IndependentModule= PreemptiveExample

ThreadSafe Function MyWorkerFunc()
   do

      String tdf= ThreadGroupGetDF(0,inf)
      if( strlen(tdf) == 0 )
         return -1              // Thread is being killed
      endif
```

```
        SetDataFolder tdf
        WAVE Kenith                // Array of frequencies to calculate
        SetDataFolder ::

        Variable i, n= numpnts(Kenith)

        for(i=0;i<n;i+=1)

            NewDataFolder/S resultsDF
            Make jack= sin(Kenith[i]*x)

            Variable t0= ticks
            do
               // waste cpu for a few seconds
            while(ticks < (t0+120))

            WAVEClear jack      // Must have no references to allow put.

            ThreadGroupPutDF 0,:
        endfor

        KillDataFolder tdf      // We are done with the input data folder

    while(1)

    return 0
End

Function myResultsFunc(s)
    STRUCT WMBackgroundStruct &s

    String dfSav= GetDataFolder(1)

    SetDataFolder root:testdf
    NVAR tgID
    String tdf= ThreadGroupGetDF(tgID,0)
    if( strlen(tdf) != 0 )
        SetDataFolder tdf
        WAVE jack           // this is the output from the thread
        AppendToGraph/W=ThreadResultsGraph jack
    endif

    SetDataFolder dfSav
    return 0
End
```

And copy this function to the main procedure window:

```
Function TestThreadQueue()
    String dfSav= GetDataFolder(1)

    NewDataFolder/O/S root:testdf // thread group ID and result datafolders go here

    variable/G tgID= ThreadGroupCreate(1)

    ThreadStart tgID,0,PreemptiveExample#MyWorkerFunc()

    // MyWorkerFunc is now running and waiting for input data
    // now, let's give it something to do
    NewDataFolder/S tasks
    Make/N=5 Kenith= 1/(10+p/2+enoise(0.2))// array of frequencies to calculate
    WAVEClear Kenith

    ThreadGroupPutDF tgID,:// thread is now crunching away

    Display as "output"
    DoWindow/C ThreadResultsGraph     // results will be appended here...

    // ...by this named task
    CtrlNamedBackground myResultsTask,period=10,proc=PreemptiveExample#myResultsFunc,start

    SetDataFolder dfSav     // be a good citizen and restore current df
End

Function PostMoreFreqs()
    NVAR tgID= root:testdf:tgID

    NewDataFolder/S moretasks
    Make/N=50 Kenith= 1/(15+p/2+enoise(0.2))// array of frequencies to calculate
    WAVEClear Kenith
```

```
   ThreadGroupPutDF tgID,:       // thread continues crunching
End
```

Once the code is compiled, on the command line execute

```
TestThreadQueue()
```

After the action stops, send more tasks to the background thread by executing

```
PostMoreFreqs()
```

While this is running, experiment with creating graphs, using dialogs, creating functions, etc. Note that both tasks run indefinitely. If you want to start over, you will need to stop the threads and kill the graph.

Cursors — Moving Cursor Calls Function

Note: The following section "The Old Easy Way" is now outdated as of Igor Pro 5 (though it still works). Use the **SetWindow** operation (page V-569) hook and the cursormoved event instead. The window hook isolates handling the cursor to the graph window in which the cursor is moving, and is no more difficult to program than the old global CursorMovedHook which is called for cursors moving in any graph window.

The Old Easy Way

You can write a "hook function" — which must be named "CursorMovedHook" — and Igor will automatically call it with one string argument containing information about the graph, trace or image, and cursor in the following format:

```
GRAPH:graphName;CURSOR:<A - J>;TNAME:traceName; MODIFIERS:modifierNum;
ISFREE:freeNum;POINT:xPointNumber; [YPOINT:yPointNumber;]
```

The CursorMovedHook function is called whenever any cursor is moved in any graph, unless Option (*Macintosh*) or Alt (*Windows*) is held down.

The *traceName* value is the name of the graph trace or image to which it is attached or which supplies the x (and y) values.

The *modifierNum* value represents the state of some of the keyboard keys summed together:

1 If Command (*Macintosh*) or Ctrl (*Windows*) is pressed.

2 If Control (*Macintosh only*) is pressed.

4 If Shift is pressed.

8 If Caps Lock is pressed.

The Option key (*Macintosh*) or Alt key (*Windows*) is not represented because it prevents the hook from being called.

The YPOINT keyword and value are present only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot or when the cursor is free.

If cursor is free, POINT and YPOINT values are fractional relative positions (see description in **Cursor** operation on page V-84). If TNAME is empty, fields POINT, ISFREE and YPOINT are not present.

This example hook function simply prints the information in the history window:

```
Function CursorMovedHook(info)
   String info
   Print info
End
```

Whenever any cursor on any graph is moved, this CursorMovedHook function will print something like the following in the history area:

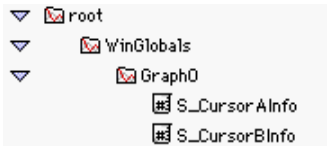
```
GRAPH:Graph0;CURSOR:A;TNAME:jack;MODIFIERS:0;ISFREE:0;POINT:6;
```

See **Example Cursor Global User Function** on page IV-296 for a more sophisticated use of this info string.

The Hard Way

It is also possible to use Igor's dependency mechanism to cause functions to execute automatically when the user moves cursors on a given graph. The advantage of this method is that the function(s) are specific to the given graph.

To do this, create a data folder named WinGlobals and within that create a data folder of the same name as the desired graph. Within that data folder create a string variable named S_CursorAInfo or S_CursorBInfo.



Cursor Globals

If these variables exist (and if Option (*Macintosh*) or Alt (*Windows*) is not held down), then when the user moves a cursor, Igor will set them to an informational string in the following format (all one line):

```
GRAPH:graphName;CURSOR:<A - J>;TNAME:traceName;MODIFIERS:modifierNum;
ISFREE:freeNum;POINT:xPointNumber;[YPOINT:yPointNumber;]
```

Moving cursor A, for example, will update S_CursorAInfo. If the cursor is being removed, traceName will be zero length.

Creating the Cursor Globals

Here is code that creates the necessary global variables for the top graph:

```
Function CursorGlobalsForGraph()
   String graphName= WinName(0,1)
   if( strlen(graphName) )
      String df= GetDataFolder(1);
      NewDataFolder/O root:WinGlobals
      NewDataFolder/O/S root:WinGlobals:$graphName
      String/G S_CursorAInfo, S_CursorBInfo
      SetDataFolder df
   endif
End
```

And code that deletes the globals:

```
Function RemoveCursorGlobals()
   String graphName= WinName(0,1)
   if( strlen(graphName) )
      KillDataFolder root:WinGlobals:$graphName
   endif
End
```

(You can arrange for RemoveCursorGlobals() to be called automatically when Graph0 is closed by setting the "window hook function" of Graph0. See the **SetWindow** operation.)

Establishing a Dependency Between Cursor Globals and a User Function

For a user-defined function to be automatically called when, for example, you move the A cursor for Graph0, you must establish a dependency involving the global WinGlobals:Graph0:S_CursorAInfo and the user-defined function.

This example establishes a dependency between additional variables and each of the cursor info globals involving the example user function shown in the next section (CursorMoved). This dependency updates WinGlobals:Graph0:dependentA by CursorMoved whenever S_CursorAInfo is changed due to cursor A being moved (and likewise for dependentB and S_CursorBInfo):

```
Function CursorDependencyForGraph()
   String graphName= WinName(0,1)
   if( strlen(graphName) )
      String df= GetDataFolder(1);
```

```
      NewDataFolder/O root:WinGlobals
      NewDataFolder/O/S root:WinGlobals:$graphName
      String/G S_CursorAInfo, S_CursorBInfo
      Variable/G dependentA
      SetFormula dependentA, "CursorMoved(S_CursorAInfo, 0)"
      Variable/G dependentB
      SetFormula dependentB,"CursorMoved(S_CursorBInfo, 1)"
      SetDataFolder df
   endif
End
```

Example Cursor Global User Function

The example user function takes two arguments. Yours must have at least one: the cursor info string that Igor automatically updates when the cursor is moved.

Inside the user function, you can parse the cursor info parameter with the **StringByKey** (page V-675) and **NumberByKey** (page V-458) functions. You can obtain additional information about the cursor using the usual routines such as hcsr and vcsr.

In almost all cases, the top graph will be the one referenced by the info string. However, it is possible to write a user function that moves the cursors and then brings a different graph to the top before your dependency fires. Therefore it is possible (though unlikely) that calling a routine like hcsr could generate an error if you don't first check that the top graph is the one referenced in the info string. (You can use `DoWindow/F graphName` to ensure that the graph is top-most.)

This simple example prints to the history area the value of a five-point average around the new cursor position whenever the cursor moves:

```
Function CursorMoved(info, isB)
   String info
   Variable isB            // 0 if A cursor, nonzero if B cursor

   Variable result= NaN    // error result
   // Check that the top graph is the one in the info string.
   String topGraph= WinName(0,1)
   String graphName= StringByKey("GRAPH", info)
   if( CmpStr(graphName, topGraph) == 0 )
      // If the cursor is being turned off
      // the trace name will be zero length.
      String tName= StringByKey("TNAME", info)
      if( strlen(tName) )  // cursor still on
         String cn
         Variable xVal
         if( isB )
            xVal= hcsr(B)
            cn= "Cursor B"
         else
            xVal= hcsr(A)
            cn= "Cursor A"
         endif
         // compute the local 5-point mean
         WAVE w= TraceNameToWaveRef(graphName, tName)
         Variable pointNum= NumberByKey("POINT",info)
         Variable x1= pnt2x(w,pointNum-2)
         Variable x2= pnt2x(w,pointNum+2)
         result= mean(w,x1,x2)
         Print cn+" on "+tName+" moved to x= ",xVal,"mean= ",result
      endif
   endif
   return result
End
```

The Result

Whenever either cursor on Graph0 is moved, the CursorMoved function will print something like the following in the history area:

```
Cursor A on wave0#1 moved to x=   33  mean=   0.0239056
```

Volume V Reference

Table of Contents

Igor Reference

This volume contains detailed information about Igor Pro's built-in operations, functions, and keywords. They are listed alphabetically after the category sections that follow.

External operations (XOPs) and external functions (XFUNCs) are not covered here. For information about them, use the Command Help tab of the Igor Help Browser.

Built-In Operations by Category

Note: some operations may appear in more than one category.

Alphabetic Listing of Functions, Operations and Keywords

This section alphabetically lists all built-in functions, operations and keywords. Much of this information is also accessible online in the Command Help tab of the Igor Help Browser.

External operations (XOPs) and external functions (XFUNCs) are not covered here. For information about them, use the Command Help tab of the Igor Help Browser and the XOP help file in the same folder as the XOP file.

Reference Syntax Guide

In the descriptions of functions and operations that follow, italics indicate parameters for which you can supply numeric or string expressions. Nonitalic parameters are to be entered literally as they appear. Commas, slashes, braces and parentheses in these descriptions are always literals. Bold brackets may also be literals; they are used to specify point ranges or indices (the description will make this clear).

Nonbold brackets surround optional flags or parameters.

Ellipses (…) indicate that the preceding element may be repeated a number of times. The exact number of repetitions varies, and should be found in the description.

Italicized parameters represent values you supply. Italic words ending with "*Name*" are names (wave names, for example), and those ending with "*Str*" (and the words "*string*" or "*str*") are strings. Some Igor functions can take an empty string ("", no space between the quotation marks) as a parameter. Italic words ending with "*Spec*" (meaning "specification") are usually further defined in the description. If none of these endings are employed, the italic word is a numeric expression, such as a literal number, the name of a variable or function, or some valid combination.

Strings and names are different, but you can use a string where a name is expected using "string substitution": precede a string expression with the $ operator. See **String Substitution Using $** on page IV-15.

A syntax description may span several lines, but the actual command you create must occupy a single line. Igor has no line continuation character like FORTRAN programs or Unix command shells.

Many operations have optional "flags". Flags that accept a value (such as the Make operation's /N=*n* flag) sometimes require additional parentheses. For example:

```
Make/N=1 aNewWave
```

is acceptable because here *n* is the literal "1". To use a numeric expression for *n*, parentheses are needed:

```
Make/N=(numberOfPoints) aNewWave              // error if no parentheses!
```

And, yes, the use of just one variable constitutes an "expression"!

Some operations have multiple forms. The syntax for each is shown on a separate line.

For more about using functions, operations and keywords, see Chapter IV-1, **Working with Commands**, Chapter IV-2, **Programming Overview**, and Chapter IV-10, **Advanced Programming**.

#define

#define *symbol*
The #define statement is a conditional compilation directive that defines a *symbol* for use only with #ifdef or #ifndef expressions. #undef removes the definition.

Details
The defined *symbol* exists only in the file where it is defined; the only exception is in the main procedure window where the scope covers all other procedures except independent modules. See **Conditional Compilation** on page IV-86 for information on defining a global *symbol*.

#define cannot be combined inline with other conditional compilation directives.

See Also
The #**undef**, #**ifdef-#endif**, and #**ifndef-#endif** statements.

Conditional Compilation on page IV-86.

#if-#elif-#endif

```
#if expression1
   <TRUE part 1>
#elif expression2
   <TRUE part 2>
[…]
[#else
   <FALSE part>]
#endif
```

In a #if-#elif-#endif conditional compilation statement, when an expression evaluates as TRUE (absolute value > 0.5), then only code corresponding to the TRUE part of that expression is compiled, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then *FALSE part* is compiled when present.

Details
Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

See Also
Conditional Compilation on page IV-86 for more usage details.

#if-#endif

```
#if expression
   <TRUE part>
[#else
   <FALSE part>]
#endif
```

A #if-#endif conditional compilation statement evaluates *expression*. If *expression* is TRUE (absolute value > 0.5) then the code in *TRUE part* is compiled, or if FALSE (zero) then the optional *FALSE part* is compiled.

Details
Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

See Also
Conditional Compilation on page IV-86 for more usage details.

#ifdef-#endif

```
#ifdef symbol
   <TRUE part>
[#else
   <FALSE part>]
#endif
```

A #ifdef-#endif conditional compilation statement evaluates *symbol*. When *symbol* is defined the code in *TRUE part* is compiled, or if undefined then the optional *FALSE part* is compiled.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

symbol must be defined before the conditional with #define.

See Also

The #**define** statement and **Conditional Compilation** on page IV-86 for more usage details.

#ifndef-#endif

```
#ifndef symbol
   <TRUE part>
[#else
   <FALSE part>]
#endif
```

An #ifndef-#endif conditional compilation statement evaluates *symbol*. When *symbol* is undefined the code in *TRUE part* is compiled, or if defined then the optional *FALSE part* is compiled.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

symbol must be defined before the conditional with #define.

See Also

The #**define** statement and **Conditional Compilation** on page IV-86 for more usage details.

#include

```
#include "file spec" or <file spec>
```

A #include statement in a procedure file automatically opens another procedure file. You should use #include in any procedure file that you write if it requires that another procedure file be open. A #include statement must always appear flush against the left margin in a procedure window.

Parameters

file spec is the procedure file name, which can incorporate a full or partial path. The form used depends of the procedure file location: <*file spec*> is in "Igor Pro Folder/WaveMetrics Procedures" and "*file spec*" is in "Igor Pro Folder/User Procedures" or "Igor Pro User Files/User Procedures".

See Also

The Include Statement on page IV-145 for usage details.

Igor Pro User Files on page II-46.

#pragma

```
#pragma [rtGlobals = 0, 1, or 2][IgorVersion = versNum]
        [version = versNum][ModuleName = name]
        [IndependentModule = name]
```

#pragma introduces a compiler directive, which is a message to the Igor procedure compiler. A #pragma statement must always appear flush against the left margin in a procedure window.

See Also

rtGlobals, **IndependentModule**, **ModuleName**, and **version** for details about these particular #pragma directives. Also see **Silent** and **Pragmas** on page IV-40.

#undef

```
#undef symbol
```

A #undef statement removes a nonglobal *symbol* created previously by #define. See **Conditional Compilation** on page IV-86 for information on undefining a global *symbol.*

See Also

The #**define** statement and **Conditional Compilation** on page IV-86 for more usage details.

Abort

Abort [*errorMessageStr*]

The Abort operation aborts procedure execution.

Parameters

The optional *errorMessageStr* is a string expression, which, if present, specifies the message to be displayed in the error alert.

Details

Abort provides a way for a procedure to abort execution when it runs into an error condition.

See Also

Aborting Functions on page IV-89 and **Aborting Macros** on page IV-103. The **DoAlert** operation.

AbortOnRTE

AbortOnRTE

The AbortOnRTE flow control keyword raises an abort with a runtime error. AbortOnRTE should be used after an operation that might give rise to a runtime error. It has very low overhead and should not significantly slow program execution.

Details

In terms of programming style, you should consider using AbortOnRTE (preceded by a semicolon) on the same line as the command that may give rise to an abort condition.

When using AbortOnRTE after a related sequence of commands, then it should be placed on its own line.

Example

Abort if the wave does not exist:

```
WAVE someWave; AbortOnRTE
```

See Also

Flow Control for Aborts on page IV-38 and **AbortOnRTE Keyword** on page IV-38 for further details.

The **try-catch-endtry** flow control statement.

AbortOnValue

AbortOnValue *abortCondition, abortCode*

The AbortOnValue flow control keyword will abort function execution when the *abortCondition* is nonzero and it will then return the numeric *abortCode*. No dialog will be displayed when such an abort occurs.

Parameters

abortCondition can be any valid numeric expression using comparison or logical operators.

abortCode is a nonzero numeric value returned to any abort or error handling code by AbortOnValue whenever it causes an abort.

See Also

Flow Control for Aborts on page IV-38 and **AbortOnValue Keyword** on page IV-38 for further details.

The **AbortOnRTE** keyword and the **try-catch-endtry** flow control statement.

abs

abs(*num*)

The abs function returns the absolute value of the real number *num*. To calculate the absolute value of a complex number, use the cabs function.

See Also

The **cabs** function.

acos

acos(*num*)

The acos function returns the inverse cosine of *num* in radians in the range [0,π].

In complex expressions, *num* is complex and acos returns a complex value.

acosh

acosh(*num*)

The acosh function returns the inverse hyperbolic cosine of *num*. In complex expressions, *num* is complex and acosh returns a complex value.

AddFIFOData

AddFIFOData *FIFOName, FIFO_channelExpr* [, *FIFO_channelExpr*]…

The AddFIFOData operation evaluates *FIFO_channelExpr* expressions as double precision floating point and places the resulting values into the named FIFO.

Details

There must be one *FIFO_channelExpr* for each channel in the FIFO.

See Also

FIFOs are used for data acquisition. See **FIFOs and Charts** on page IV-276.

Other operations used with FIFOs: **NewFIFO**, **NewFIFOChan**, **CtrlFIFO**, and **FIFOStatus**.

AddFIFOVectData

AddFIFOVectData *FIFOName, FIFO_channelKeyExpr* [, *FIFO_channelKeyExpr*]…

The AddFIFOVectData operation is similar to AddFIFOData except the expressions use a keyword to allow either a single numeric value for a normal channel or a wave containing the data for a special image vector channel.

Details

There must be one *FIFO_channelKeyExpr* for each channel in the FIFO.

A *FIFO_channelKeyExpr* may be one of:

```
num = numericExpression
vect = wave
```

For best results, the wave should have the same number of points as used to define the FIFO channel and the same number type. See the **NewFIFOChan** operation.

See Also

FIFOs and Charts on page IV-276.

AddListItem

AddListItem(*itemStr, listStr* [, *listSepStr* [, *itemNum*]])

The AddListItem function returns *listStr* after adding *itemStr* to it. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use AddListItem to add an item to a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or to a line from a delimited text file.

listSepStr and *itemNum* are optional; their defaults are ";" and 0, respectively.

Details

By default *itemStr* is added to the start of the list. Use the optional list index *itemNum* to add *itemStr* at a different location. The returned list will have *itemStr* at the index *itemNum* or at ItemsInList(*returnedListStr*)-1 when *itemNum* equals or exceeds ItemsInList(*listStr*).

itemNum can be any value from -infinity (`-Inf`) to infinity (`Inf`). Values from -infinity to 0 prepend *itemStr* to the list, and values from ItemsInList(*listStr*) to infinity append *itemStr* to the list.

itemStr may be `""`, in which case an empty item (consisting of only a separator) is added.

If *listSepStr* is `""`, then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case an empty string (`""`) is returned).

listStr is treated as if it ends with a *listSepStr* even if it doesn't.

Only the first character of *listSepStr* is used.

Examples

```
Print AddListItem("hello","kitty;cat;")        // prints "hello;kitty;cat;"
Print AddListItem("z", "b,c,", ",", 1)         // prints "b,z,c,"
Print AddListItem("z", "b,c,", ",", 999)       // prints "b,c,z,"
Print AddListItem("z", "b,c,", ",", Inf)       // prints "b,c,z,"
Print AddListItem("", "b-c-", "-")             // prints "-b-c-"
```

See Also

The **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveFromList**, **RemoveListItem**, **StringFromList**, **StringList**, **TraceNameList**, **VariableList**, and **WaveList** functions.

AddMovieAudio

AddMovieAudio *soundWave*

The AddMovieAudio operation adds audio samples to the audio track of the currently open movie.

Parameters

soundWave contains audio samples with an amplitude from -128 to +127 and with the same time scale as the prototype *soundWave* used to open the movie.

Details

You can create movies with 16-bit and stereo sound by providing a sound wave in the appropriate format. To specify 16-bit sound, the wave type must be signed 16-bit integer (/W flag in **Make** or **Redimension**). To specify stereo, use a wave with two columns (or any other number of channels as desired).

See Also

The **NewMovie** operation.

AddMovieFrame

AddMovieFrame [/PICT=*pictName*]

The AddMovieFrame operation adds the top graph or the specified picture to the currently open movie.

When you write a procedure to generate a movie, you need to call the **DoUpdate** operation after all modifications to the graph and before calling AddMovieFrame. This allows Igor to process any changes you have made to the graph.

If the /PICT flag is provided, then the specified picture from the picture collection (see **Pictures** on page III-421) is used in place of the top graph. This requires Igor Pro 6.12 or later.

See Also

The **NewMovie** operation.

airyA

airyA(*x* [, *accuracy*])

The airyA function returns the value of the Airy $Ai(x)$ function:

$Ai(x) = \frac{1}{\pi}\sqrt{\frac{x}{3}}K_{1/3}\left(\frac{2}{3}x^{3/2}\right)$ where K is the modified Bessel function.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyAD** and **airyB** functions.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

airyAD

airyAD(*x* [, *accuracy*])

The airyAD function returns the value of the derivative of the Airy function.

Details
See the **bessI** function for details on accuracy and speed of execution.

See Also
The **airyA** function.

airyB

airyB(*x* [, *accuracy*])
The airyB function returns the value of the Airy $Bi(x)$ function:

$$Bi(x) = \sqrt{\frac{x}{3}}\left[I_{-1/3}\left(\frac{2}{3}x^{3/2}\right) + I_{1/3}\left(\frac{2}{3}x^{3/2}\right)\right]$$ where I is the modified Bessel function.

Details
See the **bessI** function for details on accuracy and speed of execution.

See Also
The **airyBD** and **airyA** functions.

References
Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

airyBD

airyBD(*x* [, *accuracy*])
The airyBD function returns the value of the derivative $Bi'(x)$ of the Airy function.

Details
See the **bessI** function for details on accuracy and speed of execution.

See Also
The **airyB** function.

alog

alog(*num*)
The alog function returns 10^{num}.

AnnotationInfo

AnnotationInfo(*winNameStr*, *annotationNameStr* [, *options*])
The AnnotationInfo function returns a string containing a semicolon-separated list of information about the named annotation in the named graph or page layout window or subwindow.

The main purpose of AnnotationInfo is to use a tag or textbox as an input mechanism to a procedure. This is illustrated in the "Tags as Markers Demo" sample experiment, which includes handy utility functions (supplied by AnnotationInfo Procs.ipf).

Parameters
winNameStr can be "" to refer to the top graph or layout window or subwindow.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

options is an optional parameter that controls the text formatting in the annotation output. The default value is 0.

Omit *options* or use 0 for *options* to escape the returned annotation text, which is appropriate for printing the output to the history or for using the text in an Execute operation.

Use 1 for *options* to not escape the returned annotation text because you intend to extract the text for use in a subsequent command such as Textbox or Tag.

Details
The string contains thirteen pieces of information. The first twelve pieces are prefaced by a keyword and colon and terminated with a semicolon. The last piece is the annotation text, which is prefaced with a

keyword and a colon but is not terminated with a semicolon.

Keyword	Information Following Keyword
ABSX	X location, in points, of the anchor point of the annotation. For graphs, this is relative to the top-left corner of the graph window. For layouts, it is relative to the top-left corner of the page.
ABSY	Y location, in points, of the anchor point of the annotation. For graphs, this is relative to the top-left corner of the graph window. For layouts, it is relative to the top-left corner of the page.
ATTACHX	For tags, it is the X value of the wave at the point where the tag is attached, as specified with the Tag operation. For textboxes, color scales, and legends, this will be zero and has no meaning.
AXISX	X location of the anchor point of the annotation. For tags or color scales in graphs, it is in terms of the X axis against which the tagged wave is plotted. For textboxes and legends in graphs, it is in terms of the first X axis. For layouts, this has no meaning and is always zero.
AXISY	Y location of the anchor point of the annotation. For layouts, this has no meaning and is always zero. For tags or color scales in graphs, it is in terms of the Y axis against which the tagged wave is plotted. For textboxes and legends in graphs, it is in terms of the first Y axis.
AXISZ	Z value of the image or contour level trace to which the tag is attached or NaN if the trace is not a contour level trace or the annotation is not a tag.
COLORSCALE	Parameters used in a ColorScale operation to create the annotation.
FLAGS	Flags used in a Tag, Textbox, ColorScale, or Legend operation to create the annotation.
RECT	The outermost corners of the annotation (values are in points): RECT:*left*, *top*, *right*, *bottom*
TEXT	Text that defines the contents of the annotation or the main axis label of a color scale.
TYPE	Annotation type: “Tag”, “Textbox”, “ColorScale”, or “Legend”.
XWAVE	For tags, it is the name of the X wave in the XY pair to which the tag is attached. If the tag is attached to a single wave rather than an XY pair, this will be empty. For textboxes, color scales, and legends, this will be empty and has no meaning.
XWAVEDF	For tags, the full path to the data folder containing the X wave associated with the trace to which the tag is attached. For textboxes, color scales, and legends, this will be empty and has no meaning.
YWAVE	For tags, it is the name of the trace or image to which the tag is attached. See **ModifyGraph (traces)** and **Instance Notation** on page IV-16 for discussions of trace names and instance notation. For color scales, it is the name of the wave displayed in associated the contour plot, image plot, f(z) trace, or the name of the color scale’s cindex wave. For textboxes and legends, this will be empty and has no meaning.
YWAVEDF	Full path to the data folder containing the Y wave or blank if the annotation is not a tag or color scale.

AnnotationList

`AnnotationList(`*`winNameStr`*`)`

The AnnotationList function returns a semicolon-separated list of annotation names from the named graph or page layout window or subwindow.

Parameters

winNameStr can be `""` to refer to the top graph or layout window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

APMath

APMath [*flags*] *destStr = Expression*

The APMath operation provides arbitrary precision calculation of basic mathematical expressions. It converts the final result into the assigned string *destStr*, which can then be printed or used to represent a value (at the given precision) in another APMath operation.

Parameters

destStr Specifies a destination string for the assignment expression. If *destStr* is not an existing variable, it is created by the operation. When executing in a function, *destStr* will be a local variable if it does not already exist.

Expression Algebraic expression containing constants, local, global, and reference variables or strings, as well as wave elements together with the following operators:

Operator	Precedence
^	**Highest**
* /	
+ -	**Lowest**

Operators

Supported operators are:

+	Scalar addition.
-	Scalar subtraction.
*	Scalar multiplication.
/	Scalar division.
^	Exponentiation.

Functions

The following functions are supported:

sqrt(*x*)	Square root of *x*.
cbrt(*x*)	Cube root of *x*.
pi	Value of π (without parentheses).
sin(*x*)	Sine of *x*.
cos(*x*)	Cosine of *x*.
tan(*x*)	Tangent of *x*.
asin(*x*)	Inverse sine of *x*.
acos(*x*)	Inverse cosine of *x*.
atan(*x*)	Inverse tangent of *x*.
atan2(*y*,*x*)	Inverse tangent of *y*/*x*.
log(*x*)	Logarithm of *x*.
log10(*x*)	Logarithm based 10 of *x*.
exp(*x*)	Exponential function e^*x*.
pow(*x*,*n*)	*x* to the power *n* (*n* not necessarily integer).
sinh(*x*)	Hyperbolic sine of *x*.
cosh(*x*)	Hyperbolic cosine of *x*.
tanh(*x*)	Hyperbolic tangent of *x*.
asinh(*x*)	Inverse hyperbolic sine of *x*.
acosh(*x*)	Inverse hyperbolic cosine of *x*.
atanh(*x*)	Inverse hyperbolic tangent of *x*.
ceil(*x*)	Smallest integer larger than *x*.

`comp(x,y)`	Returns 0 for $x == y$, 1 if $x > y$ and -1 if $y > x$.
`factorial(n)`	Factorial of integer n.
`floor(x)`	Greatest integer smaller than x.
`gcd(x,y)`	Greatest common divisor of x and y.
`lcd(x,y)`	Lowest common denominator of x and y (given by $x*y$/gcd(x,y).
`sgn(x)`	Sign of x or zero if $x == 0$.

Flags

/EX=*exDigits*	Specifies the number of extra digits added to the precision digits (/N) for intermediate steps in the calculation.
/N=*numDigits*	Specifies the precision of the final result. To add digits to the intermediate computation steps, use /EX.
/V	Verbose mode; prints the result in the history in addition to performing the assignment.
/Z	No error reporting.

Details

By default, all arbitrary precision math calculations are performed with *numDigits*=50 and *exDigits*=6, which yields a final result using at least 56 decimal places. Because none of the built-in variable types can express numbers with such high accuracy, the arbitrary precision numbers must be stored as strings. The operation automatically converts between strings and constants. It evaluates all of the numerical functions listed above using the specified accuracy. If you need functions that are not supported by this operation, you may have to precompute them and store the results in a local variable.

The operation stores the result in *destStr*, which may or may not exist prior to execution. When you execute the operation from the command line, *destStr* becomes a global string in the current data folder if it does not already exist. If it exists, then the result of the operation overwrites its value (as with any normal string assignment). In a user function, *destStr* can be a local string, an SVAR, or a string passed by reference. If *destStr* is not one of these then the operation creates a local string by that name.

Arbitrary precision math calculations are much slower (by a factor of about 300) than equivalent floating point calculations. Execution time is a function of the number of digits, so you should use the /N flag to limit the evaluation to the minimum number of required digits.

Examples

Evaluate pi to 50 digits:

```
APMath/V aa=pi
```

Evaluate ratios of large factorials:

```
APMath/v aa=factorial(500)/factorial(499)
```

Evaluate ratios of large exponentials:

```
APMath/v aa=exp(-1000)/exp(-1001)
```

Division of mixed size values:

```
APMath/v aa=1-sgn(1-(1-0.00000000000000000001234)/(1-0.000000000000000000012345)))
```

you'll get a different result trying to evaluate this using double precision.

Difference between built-in pi and the arbitrary precision pi:

```
Variable/G biPi=pi
APMath/v aa=biPi-pi
```

Precision control:

```
Function test()
   APMath aa=pi                  // Assign 50 digit pi to the string aa.
   APMath/v bb=aa                // Create local string bb equal to aa.
   APMath/v bb=aa-pi             // Subtract arb. prec. pi from aa.
                                 // note the default exDigits=6.
   APMath/v/n=50/ex=0 bb=aa-pi   // setting exDigits=0.
End
```

Numerical recreation:

```
APMath/v/n=16 aa=111111111^2
```

Append

Append

The Append operation is interpreted as **AppendToGraph**, **AppendToTable**, or **AppendToLayout**, depending on the target window. This does not work when executing a user-defined function. Therefore we now recommend that you use **AppendToGraph**, **AppendToTable**, or **AppendLayoutObject** rather than Append.

AppendImage

AppendImage [**/G=*g*/W=*winName***][***axisFlags***] ***matrix*** [**vs** {***xwaveName*, *ywaveName***}]

The AppendImage operation appends the matrix as an image to the target or named graph. By default the image is plotted versus the left and bottom axes.

Parameters

matrix is either an NxM matrix for false color or indexed color images or can be a 3D NxMx3 wave containing a layer of data for red, a layer for green and a layer for blue. If matrix contains multiple planes other than three or if it contains 3 planes and multiple chunks, the **ModifyImage** plane keyword can be used to specify the desired subset to display.

If you provide *xwaveName* and *ywaveName*, *xwaveName* provides X coordinate values, and *ywaveName* provides Y coordinate values. This makes an image with uneven pixel sizes. In both cases, you can use * to specify calculated values. See **Details** if you use *xwaveName* or *ywaveName*.

Flags

axisFlags	Flags /L, /R, /B, and /T are the same as used by **AppendToGraph**.
/G=*g*	*g*=1: Suppresses the autodetection of three plane images as direct (RGB) color.
	g= 0: Same as no /G flag (default).
/W=*winName*	Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
	When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

When appending an image to a graph, you can supply optional X and Y waves to define the coordinates of the rectangle edges. *These waves need to contain one more data point than the X (row) or Y (column) dimension of the matrix to define the end of the last rectangle*.

For false color, the values in the matrix are linearly mapped into a color table. See the **ModifyImage ctab** keyword. For indexed color, the values in the matrix are interpreted as Z values to be looked up in a user-supplied 3 column matrix of colors. See the **ModifyImage cindex** keyword. Direct color NxMx3 waves contain the actual red, green, and blue values for each pixel. If the number type is unsigned bytes, then the range of intensity ranges from 0 to 255. For all other number types, the intensity ranges from 0 to 65535.

By default, nondirect color matrices are initially displayed as false color using the Grays color table and autoscale mode.

If the matrix is complex, the image is displayed in terms of the magnitude of the Z value, that is, $\text{sqrt}(\text{real}^2 + \text{imag}^2)$.

See Also

The **NewImage**, **ModifyImage**, and **RemoveImage** operations. For general information on image plots see Chapter II-15, **Image Plots**.

AppendLayoutObject

AppendLayoutObject [***flags***] ***objectType objectName***

The AppendLayoutObject operation appends a single object to the top layout or to the layout specified via the /W flag.

Unlike the AppendToLayout operation, AppendLayoutObject can be used in user-defined functions. Therefore, AppendLayoutObject should be used in new programming instead of AppendToLayout.

Parameters

objectType identifies the type of object to be appended. It is one of the following keywords: `graph`, `table`, `picture`.

objectName is the name of the graph, table or picture to be appended.

Use a space between *objectType* and *objectName*. A comma is not allowed.

Flags

/D=*fidelity*	Draws layout objects in low fidelity (*fidelity*=0) or high fidelity (*fidelity*=1; default). This affects drawing on the screen only, not exporting or printing. Low fidelity is somewhat faster but less accurate and should be used only for graphs that take a very long time to draw.
/F=*frame*	Specifies the type of frame enclosing the object. *frame* =0: None. *frame* =1: Single frame (default). *frame* =2: Double frame. *frame* =3: Triple frame. *frame* =4: Shadow frame.
/T=*trans*	Sets the transparency of the object background to opaque (*trans* =0; default) or transparent (*trans* =1). For transparency to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. PICTs may have been created transparent or opaque. Opaque PICTs cannot be made transparent.
/R=(*l*, *t*, *r*, *b*)	Sets the size and position of the object. If omitted, the object is placed with a default size and position. *l*, *t*, *r*, and *b* are the left, top, right, and bottom coordinates of the object, respectively. Coordinates are expressed in units of points, relative to the top/left corner of the paper.
/W=*winName*	Appends the object to the named page layout window. If /W is omitted or if *winName* is `$""`, the top page layout is used.

See Also

NewLayout, **ModifyLayout**, **RemoveLayoutObjects**, **TextBox**, and **Legend**.

AppendMatrixContour

AppendMatrixContour [***axisFlags***] [**/F=*formatStr* /W=*winName***] ***zWave***
[**vs** {***xWave, yWave***}]

The AppendMatrixContour operation appends to the target or named graph a contour plot of a matrix of z values with autoscaled contour levels, using the Rainbow color table.

Note: There is no DisplayContour operation. Use `Display; AppendMatrixContour`.

Parameters

zWave must be a matrix (2D wave).

To contour a set of XYZ triplets, use **AppendXYZContour**.

If you provide the *xWave* and *yWave* specification, *xWave* provides X values for the rows, and *yWave* provides Y values for the columns. This results in an "uneven grid" of Z values.

If you omit the *xWave* and *yWave* specification, Igor uses the *zWave*'s X and Y scaled indices as the X and Y values. Igor also uses the *zWave*'s scaled indices if you use * (asterisk symbol) in place of *xWave* or *yWave*.

In a procedure, to modify the appearance of contour levels before the contour is calculated and displayed with the default values, append "`;DelayUpdate`" and immediately follow the AppendMatrixContour command with the appropriate **ModifyContour** commands. All but the last ModifyContour command should also have `;DelayUpdate` appended.

On the command line, the Display command and following AppendMatrixContour and ModifyContour commands can be typed all on one line with semicolons between:

```
Display; AppendMatrixContour MyMatrix; ModifyContour …
```

Flags

axisFlags	Flags /L, /R, /B, /T are the same as used by **AppendToGraph**.
/F=*formatStr*	Determines the names assigned to the contour level traces. See **Details**.
/W=*winName*	Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

AppendMatrixContour creates and displays contour level traces. You can modify these all together using the Modify Contour Appearance dialog or individually using the Modify Trace Appearance dialog. In most cases, you will not need to modify the individual traces.

By default, Contour level traces are automatically named with names that show the *zWave* and the contour level, for example, "zWave=1.5". You will see these trace names in the Modify Trace Appearance dialog and in Legends. In most cases, the default trace names will be just fine.

If you want to control the names of the contour level traces (which you might want to do for names in a Legend), use the /F=*formatStr* flag. This flag uses a format string as described for the **printf** operation. The default format string is `"%.17s=%g"`, resulting in trace names such as "zWave=1.5". *formatStr* must contain at least `%f` or `%g` (used to insert the contour level) or `%d` (used to insert the zero-based index of the contour level). Include `%s`, to insert the *zWave* name.

Here are some examples of format strings.

formatStr	Examples of Resulting Name	Format
`"%g"`	"100", "1e6", "-2.05e-2"	(<level>)
`"z=%g"`	"z=100", "z=1e6", "z=-2.05e-2"	(z=<level>)
`"%s %f"`	"zWave 100.000000"	(<wave>, space, <level>)
`"[%d]=%g"`	"[0]=100", "[1]=1e6"	([<index>]=<level>)

Examples

```
Make/O/N=(25,25) w2D                    // Make a matrix
SetScale x -1, 1, w2D                   // Set row scaling
SetScale y -1, 1, w2D                   // Set column scaling
w2D = sin(x) * cos(y)                   // Store values in the matrix
Display; AppendMatrixContour w2D; DelayUpdate
ModifyContour w2D autoLevels={*,*,9}    // roughly 9 automatic levels
```

See also

AppendToGraph for details about other axis flags. The **AppendXYZContour**, **ModifyContour**, and **RemoveContour** operations. For general information on contour plots, see Chapter II-14, **Contour Plots**.

AppendText

AppendText [**/W=*winName*/N/NOCR** [**=*n***]] ***textStr***

The AppendText operation appends a carriage return and *textStr* to the most recently created or changed annotation, or to the named annotation in the target or graph or layout window. Annotations include tags, textboxes, color scales, and legends.

Parameters

textStr can contain escape codes to control font, font size and other stylistic variations.

Flags

/N=*name*	Appends *textStr* to the named tag or textbox.
/NOCR[=*n*]	Omits the initial appending of a carriage return (allows a long line to be created with multiple AppendText commands). /NOCR=0 is the same as no /NOCR, and /NOCR=1 is the same as just /NOCR.
/W=*winName*	Appends to an annotation in the named graph, layout window, or subwindow. Without /W, AppendText appends to an annotation in the topmost graph or layout

window or subwindow. This must be the first flag specified when AppendText is used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

A textbox, tag, or legend can contain at most 100 lines. A color scale can have at most one line, and this line is the color scale's main axis label.

See Also

The **Tag**, **TextBox**, **ColorScale**, **ReplaceText**, and **Legend** operations.

AppendToGraph

AppendToGraph [***flags***] ***waveName*** [**,** ***waveName***]…[**vs** ***xwaveName***]

The AppendToGraph operation appends the named waves to the target or named graph. By default the waves are plotted versus the left and bottom axes.

Parameters

The *waveName*s parameters are the names of existing waves.

vs *xwaveName* plots the data values of *waveName*s against the data values of *xwaveName*.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-288.

You can provide a custom name for a trace by appending /TN=traceName to the waveName specification. This may be useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-71 for more information. This feature was added in Igor Pro 6.20.

Flags

/B [=*axisName*]	Plots X coordinates versus the standard or named bottom axis.
/C=(*r*,*g*,*b*)	*r*, *g*, and *b* specify the amount of red, green, and blue in the color of the appended waves as an integer from 0 to 65535.
/L [=*axisName*]	Plots Y coordinates versus the standard or named left axis.
/NCAT	Causes trace to be plotted normally on what otherwise is a category plot. X values are just category numbers but can be fractional. Category numbers start from zero. This can be used to overlay the original data points for a box plot.
/Q	Uses a special, quick update mode when appending to a pair of existing axes. A side effect of this mode is that waves that are appended are marked as not modified. This will prevent other graphs containing these waves, if any, from being updated properly.
/R [=*axisName*]	Plots Y coordinates versus the standard or named right axis.
/T [=*axisName*]	Plots X coordinates versus the standard or named top axis.
/VERT	Plots data vertically. Similar to SwapXY (**ModifyGraph (axes)**) but on a trace-by-trace basis.
/W=*winName*	Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

See Also

The **Display** operation.

AppendToLayout

AppendToLayout [***flags***] ***objectSpec*** [**,** ***objectSpec***]…

The AppendToLayout operation appends the specified objects to the top layout.

The AppendToLayout operation can not be used in user-defined functions. Use the AppendLayoutObject operation instead.

Parameters

The optional *objectSpec* parameters identify a graph, table, textbox or PICT to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See the **Layout** operation for details.

Flags

/G=*g*	Specifies grout, the spacing between tiled objects. Units are points unless /I, /M, or /R are specified.
/I	*objectSpec* coordinates are in inches.
/M	*objectSpec* coordinates are in centimeters.
/R	*objectSpec* coordinates are in percent of printing part of the page.
/S	Stacks objects.
/T	Tiles objects.

See Also

The **Layout** and **AppendLayoutObject** operations for use with user-defined functions.

AppendToTable

AppendToTable [**/W=*winName***] ***columnSpec*** [**, *columnSpec***]…

The AppendToTable operation appends the specified columns to the top table. *columnSpec*s are the same as for the **Edit** operation; usually they are just the names of waves.

Flags

/W=*winName*	Appends columns to the named table window or subwindow. When omitted, action will affect the active window or subwindow. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

See Also

Edit for details about *columnSpec*s, and **RemoveFromTable**.

AppendXYZContour

AppendXYZContour [**/W=*winName* /F=*formatStr***][***axisFlags***] ***zWave*** [**vs** {***xWave, yWave***}]

The AppendXYZContour operation appends to the target or named graph a contour of a 2D wave consisting of XYZ triples with autoscaled contour levels and using the Rainbow color table.

To contour a matrix of Z values, use **AppendMatrixContour**.

Note: There is no DisplayContour operation. Use `Display; AppendXYZContour`.

Parameters

If you provide the *xWave* and *yWave* specification, *xWave* provides X values for the rows, and *yWave* provides Y values for the columns, *zWave* provides Z values and all three waves must be 1D. All must have at least four rows and must have the same number of rows.

If you omit the *xWave* and *yWave* specification, *zWave* must be a 2D wave with 4 or more rows and 3 or more columns. The first column is X, the second is Y, and the third is Z. Any additional columns are ignored.

If any of X, Y, or Z in a row is blank, (NaN), that row is ignored.

To modify the appearance of contour levels before the contour is calculated and displayed with the default values, append "`;DelayUpdate`" and immediately follow the AppendXYZContour command with the appropriate **ModifyContour** commands. All but the last **ModifyContour** command should also have `;DelayUpdate` appended

On the command line, the **Display** command and subsequent AppendXYZContour commands and any **ModifyContour** commands can be typed all on one line with semicolons between:

```
Display; AppendXYZContour MyMatrix; ModifyContour …
```

Flags

axisFlags	Flags /L, /R, /B, and /T are the same as used by **AppendToGraph**.
/F=*formatStr*	Determines names assigned to the contour level traces. This is the same as for **AppendMatrixContour**.
/W=*winName*	Appends to the named graph window or subwindow. When omitted, action affects the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

AppendXYZContour creates and displays contour level traces. You can modify these as a group using the Modify Contour Appearance dialog or individually using the Modify Trace Appearance dialog. In most cases, you will have no need to modify the traces individually.

See **AppendMatrixContour** for a discussion of how the contour level traces are named.

Examples

```
Make/O/N=(100) xW, yW, zW               // Make X, Y, and Z waves
xW = sawtooth(2*PI*p/10)                // Generate X values
yW = trunc(p/10)/10                     // Generate Y values
zW = sin(2*PI*xW)*cos(2*PI*yW)          // Generate Z values
Display; AppendXYZContour zW vs {xW, yW}; DelayUpdate
ModifyContour zW autoLevels={*,*,9}     // roughly 9 automatic levels
```

area

area(*waveName* [, *x1*, *x2*])

The area function returns the signed area between the named wave and the line y=0 from x=*x1* to x=*x2* using trapezoidal integration, accounting for the wave's X scaling. If your data are in the form of an XY pair of waves, see **areaXY**.

Details

If *x1* and *x2* are not specified, they default to -∞ and +∞, respectively.

If *x1* or *x2* are not within the X range of *waveName*, area limits them to the nearest X range limit of *waveName*.

If any values in the X range are NaN, area returns NaN.

Reversing the order of *x1* and *x2* changes the sign of the returned area.

The area operation is intended to work on 1D waves only.

Examples

```
Make/O/N=100 data;SetScale/I x 0,Pi,data
data=sin(x)
Print area(data,0,Pi)          // the entire X range, and no more
Print area(data)               // same as -infinity to +infinity
Print area(data,Inf,-Inf)      // +infinity to -infinity
```

The following is printed to the history area:

```
•Print area(data,0,Pi)         // the entire X range, and no more
  1.99983
•Print Print area(data)        // same as -infinity to +infinity
  1.99983
•Print area(data,Inf,-Inf)     // +infinity to -infinity
  -1.99983
```

The `-Inf` value was limited to 0 and `Inf` was limited to `Pi` to keep them within the X range of data.

See Also

The figure "Comparison of area, faverage and mean functions over interval (12.75,13.32)", in the **Details** section of the **faverage** function.

The **Integrate** operation.

For XY data, see **areaXY**.

areaXY

areaXY(*XWaveName, YWaveName* [, *x1, x2*])

The areaXY function returns the signed area between the named *YWaveName* and the line y=0 from x=*x1* to x=*x2* using trapezoidal integration with X values supplied by *XWaveName*.

This function is identical to the **area** function except that it works on an XY wave pair.

Details

If *x1* and *x2* are not specified, they default to -∞ and +∞, respectively.

If *x1* or *x2* are outside the X range of *XWaveName*, areaXY limits them to the nearest X range limit of *XWaveName*.

If any Y values in the specified X range are NaN, areaXY returns NaN.

Reversing the order of *x1* and *x2* changes the sign of the returned area.

If *x1* or *x2* are not found in *XWaveName*, a Y value is found by linear interpolation based on the two bracketing X values and the corresponding values from *YWaveName*.

The values in *XWaveName* may be increasing or decreasing. AreaXY assumes that the values in *XWaveName* are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any X values are NaN, the result is NaN.

See the figure "Comparison of area, faverage and mean functions over interval (12.75,13.32)", in the **Details** section of the **faverage** function.

The areaXY operation is intended to work on 1D waves only.

Examples

```
Make/O/N=101 Xdata, Ydata
Xdata = x*pi/100
Ydata = sin(Xdata[p])
Print areaXY(Xdata, Ydata,0,Pi)         // the entire X range, and no more
Print areaXY(Xdata, Ydata)              // same as -infinity to +infinity
Print areaXY(Xdata, Ydata,Inf,-Inf)     // +infinity to -infinity
```

The following is printed to the history area:

```
•Print areaXY(Xdata, Ydata,0,Pi)        // the entire X range, and no more
  1.99984
•Print areaXY(Xdata, Ydata)             // same as -infinity to +infinity
  1.99984
•Print areaXY(Xdata, Ydata,Inf,-Inf)    // +infinity to -infinity
  -1.99984
```

The `-Inf` value was limited to `0`, and `Inf` was limited to `Pi` to stay within the X range of data.

See Also

The **Integrate** operation and the **area**, **faverage**, **faverageXY**, and **PolygonArea** functions.

asin

asin(*num*)

The asin function returns the inverse sine of num in radians in the range [-π/2,π/2].

In complex expressions, *num* is complex, and asin returns a complex value.

asinh

asinh(*num*)

The asinh function returns the inverse hyperbolic sine of *num*. In complex expressions, *num* is complex, and asinh returns a complex value.

atan

atan(*num*)

The atan function returns the inverse tangent of *num* in radians. In complex expressions, *num* is complex, and atan returns a complex value. Results are in the range -π/2 to π/2.

atan2

atan2(*y1, x1*)

The atan2 function returns the angle in radians whose tangent is *y1*/*x1*. Results are in the range -π to π.

atanh

atanh(*num*)

The atanh function returns the inverse hyperbolic tangent of *num*. In complex expressions, *num* is complex, and atanh returns a complex value.

AutoPositionWindow

AutoPositionWindow [**/E/M=*m*/R=*relWindow***] [***windowName***]

The AutoPositionWindow operation positions the window specified by *windowName* relative to the next lower window of the same kind or relative to the window given by the /R flag. If *windowName* is not specified, AutoPositionWindow acts on the target window.

Flags

/E — Uses entire area of the monitor. Otherwise, it takes into account the command window.

/M=*m* — Specifies the window positioning method.

- *m*=0: Positions *windowName* to the right of the other window, if possible. If there is no room, then it positions *windowName* just below the other window but at the left edge of the display area. If that is not possible, then the position is not affected.
- *m*=1: Positions *windowName* just under the other window lined up on the left edge, if possible. If there is no room, then it positions *windowName* just to the right of the other window lined up on the bottom edges. If neither are possible then it positions *windowName* as far to the bottom and right as it will go.

/R=*relWindow* — Positions *windowName* relative to *relWindow*.

AxisInfo

AxisInfo(*graphNameStr, axisNameStr*)

The AxisInfo function returns a string containing a semicolon-separated list of information about the named axis in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

axisNameStr is the name of the graph axis.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are:

Keyword	Information Following Keyword
AXFLAG	Flag used to select the axis in any of the operations that display waves (Display, AppendMatrixContour, AppendImage, etc.).
AXTYPE	Axis type, such as “left”, “right”, “top”, or “bottom”.
CATWAVE	Wave supplying the categories for the axis if this is a category plot.
CATWAVEDF	Full path to data folder containing category wave.
CWAVE	Name of wave controlling named axis.
CWAVEDF	Full path to data folder containing controlling wave.
HOOK	Name set by ModifyFreeAxis with hook keyword.
ISCAT	Truth that this is a category axis (used in a category plot).

Keyword	Information Following Keyword
ISTFREE	Truth that this is truly free axis (created via NewFreeAxis).
MASTERAXIS	Name set by ModifyFreeAxis with master keyword.
RECREATION	List of keyword commands as used by ModifyGraph command. The format of these keyword commands is: *keyword*(x)=*modifyParameters*;
SETAXISCMD	Full SetAxis command.
SETAXISFLAGS	Flags that would be used with the SetAxis function to set the particular auto-scaling behavior that the axis uses. If the axis uses a manual axis range, SETAXISFLAGS is blank.
UNITS	Axis units, if any.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword up to the ";", prepend "ModifyGraph", replace the "x" with the name of an actual axis and then **Execute** the resultant string as a command.

Examples

```
Make/O data=x;Display data
Print StringByKey("CWAVE", AxisInfo("","left"))      // prints data
```

See Also

The **StringByKey** and **NumberByKey** functions.

The **GetAxis** and **SetAxis** operations.

The #include <Readback ModifyStr> procedures are useful for parsing strings returned by AxisInfo.

AxisList

AxisList(*graphNameStr*)

The AxisList function returns a semicolon-separated list of axis names from the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Examples

```
Make/O data=x;Display/L/T data
Print AxisList("")               // prints left;top;
```

AxisValFromPixel

AxisValFromPixel(*graphNameStr, axNameStr, pixel*)

The AxisValFromPixel function returns an axis value corresponding to the local graph pixel coordinate in the graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

If the specified axis is not found and if the name is "left" or "bottom" then the first vertical or horizontal axis will be used. Sources for *pixel* value may be the GetWindow operation or a user window hook with the mousemoved and mousedown event messages (see the **SetWindow** operation).

If *graphNameStr* references a subwindow, *pixel* is relative to top left corner of base window, not the subwindow.

See Also
The **PixelFromAxisVal** and **TraceFromPixel** functions; the **GetWindow** and **SetWindow** operations.

BackgroundInfo

BackgroundInfo

The BackgroundInfo operation returns information about the current unnamed background task.

BackgroundInfo works only with the unnamed background task. New code should used named background tasks instead. See **Background Tasks** on page IV-279 for details.

Details

Information is returned via the following variables:

V_flag	0:	No background task is defined.
	1:	Background task is defined, but not running (is idle).
	2:	Background task is defined and is running.
V_period	DeltaTicks value set by CtrlBackground. This is how often the background task runs.	
V_nextRun	Ticks value when the task will run again. 0 if the task is not scheduled to run again.	
S_value	Text of the numeric expression that the background task executes, as set by SetBackground.	

See Also

The **SetBackground**, **CtrlBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and the **ticks** function. See **Background Tasks** on page IV-279 for usage details.

Beep

Beep

The Beep operation plays the current alert sound (*Macintosh*) or the system beep sound (*Windows*).

Besseli

Besseli(*n*,*z*)

The Besseli function returns the modified Bessel function of the first kind, I*n*(*z*), of order *n* and argument *z*. Replaces the bessI function, which is supported for backwards compatibility only.

If *z* is real, Besseli returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders *n*, as well as real or complex arguments *z*.

See Also

The **Besselj**, **Besselk**, and **Bessely** functions.

Besselj

Besselj(*n*,*z*)

The Besselj function returns the Bessel function of the first kind, J*n* (*z*), of order *n* and argument *z*. Replaces the bessJ function, which is supported for backwards compatibility only.

If *z* is real, Besselj returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders *n*, as well as real or complex arguments *z*.

See Also

The **Besseli**, **Besselk**, and **Bessely** functions.

Besselk

Besselk(*n*,*z*)

The Besselk function returns the modified Bessel function of the second kind, K*n*(*z*), of order *n* and argument *z*. Replaces the bessK function, which is supported for backwards compatibility only.

If *z* is real, Besselk returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional orders *n*, as well as real or complex arguments *z*.

See Also

The **Besseli**, **Besselj**, and **Bessely** functions.

Bessely

Bessely(*n*,*z*)

The Bessely function returns the Bessel function of the second kind, Y*n*(*z*), of order *n* and argument *z*. Replaces the bessY function, which is supported for backwards compatibility only.

If *z* is real, Bessely returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders *n*, as well as real or complex arguments *z*.

See Also

The **Besseli**, **Besselj**, and **Besselk** functions.

bessI

bessI(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Besseli**.

The bessI function returns the modified Bessel function of the first kind, I*n*(*x*) of order *n* and argument *x*.

For real *x*, the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order *n* is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If *x* is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order *n* can be fractional, and must be real.

Details

The *algorithm* parameter has three options, each selecting a different calculation method:

Algorithm	What You Get
0 (default)	Uses a calculation method that has fractional accuracy better than 10^{-6} everywhere and is generally better than 10^{-8}. This method does not handle fractional order *n*; the order is truncated to an integer before the calculation is performed. Algorithm 0 is fastest by a large margin.
1	Allows fractional order. The calculation is performed using methods described in *Numerical Recipes in C*, 2nd edition, pp. 240-245. Using algorithm 1, *accuracy* specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 1e-7 (that is, 10^{-7}), that means that you wish that the absolute value of $(f_{actual} - f_{returned})/f_{actual}$ be better than 10^{-7}. Asking for less accuracy gives some increase in speed.

Algorithm	What You Get
	You pay a heavy price for higher accuracy or fractional order. When *algorithm* is nonzero, calculation time is increased by an order of magnitude for small *x*; at larger *x* the penalty is even greater. If accuracy is greater than 10^{-8} and *n* is an integer, algorithm 0 is used. The algorithm calculates bessI and bessK simultaneously. Both values are stored, and if a call to bessI is followed by a call to bessK (or bessK is followed by bessI) with the same *n*, *x*, and *accuracy* the previously-stored value is returned, making the second call very fast.
2	Fractional order is allowed. The calculation is performed using code from the SLATEC library. The accuracy achievable is often better than algorithm 1, but not always. Algorithm 2 is 1.5 to 3 times faster than algorithm 1, but still slower than algorithm 0. The accuracy parameter is ignored.

The achievable accuracy of algorithms 1 and 2 is a complicated function *n* and *x*. To see a summary of achievable accuracies choose File→Example Experiments→Testing and Misc→Bessel Accuracy menu item.

bessJ

bessJ(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Besselj**.

The bessJ function returns the Bessel function of the first kind, J*n*(*x*) of order *n* and argument *x*.

For real *x*, the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order *n* is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If *x* is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order *n* can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for bessJ and bessY are calculated simultaneously. The values are stored, and a subsequent call to bessY after a call to bessJ (or vice versa) with the same *n*, *x*, and *accuracy* will be very fast.

bessK

bessK(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Besselk**.

The bessK function returns the modified Bessel function of the second kind, K*n*(*x*) of order *n* and argument *x*.

For real *x*, the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order *n* is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If *x* is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order *n* can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for bessJ and bessY are calculated simultaneously. The values are stored, and a subsequent call to bessY after a call to bessJ (or vice versa) with the same *n*, *x*, and *accuracy* will be very fast.

bessY

bessY(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Bessely**.

The bessY function returns the Bessel function of the second kind, Y*n*(*x*) of order *n* and argument *x*.

For real *x*, the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order *n* is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If *x* is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order *n* can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for bessJ and bessY are calculated simultaneously. The values are stored, and a subsequent call to bessY after a call to bessJ (or vice versa) with the same *n*, *x*, and *accuracy* will be very fast.

beta

beta(*a*, *b*)

The beta function returns for real or complex arguments Gamma(*a*)Gamma(*b*)/Gamma(*a* + *b*) with *Re*(*a*), *Re*(*b*)>0.

See Also

The **gamma** function.

betai

betai(*a*, *b*, *x* [, *accuracy*])

The betai function returns the regularized incomplete beta function I*x*(*a*,*b*), where *a*,*b* > 0, and 0 ≤ *x* ≤ 1. Optionally, *accuracy* can be used to specify the desired fractional accuracy.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7}, that means that you wish that the absolute value of $(f_{actual} - f_{returned})/f_{actual}$ be less than 10^{-7}.

Larger values of *accuracy* (poorer accuracy) result in evaluation of fewer terms of a series, which means the function executes somewhat faster.

A single-precision level of accuracy is about $3x10^{-7}$, double-precision is about $2x10^{-16}$. The betai function will return full double-precision accuracy for small values of *a* and *b*. Achievable accuracy declines as *a* and *b* increase:

a	*b*	*x*	betai	Accuracy Achievable
1	1.5	0.5	0.646447	$2x10^{-16}$ (full double precision)
8	10	0.5	0.685470	$6x10^{-16}$
20	21	0.5	0.562685	$2x10^{-15}$
20	21	0.1	$1.87186x10^{-10}$	$5x10^{-15}$

BinarySearch

BinarySearch(*waveName*, *val*)

The BinarySearch function performs a binary search of the one-dimensional *waveName* for the value *val*. BinarySearch returns an integer point number p such that *waveName*[p] and *waveName*[p+1] bracket *val*. If *val* is in *waveName*, then *waveName*[p]==*val*.

Details

BinarySearch is useful for finding the point in an XY pair that corresponds to a particular X coordinate.

WaveName must contain monotonically increasing or decreasing values.

BinarySearch returns -1 if *val* is not within the range of values in the wave, but would numerically be placed before the first value in the wave.

BinarySearch returns -2 if *val* is not within the range of values in the wave, but would fall after the last value in the wave.

BinarySearch returns -3 if the wave has zero points.

Examples

```
Make/O data = {1, 2, 3.3, 4.9}       // Monotonic increasing
Print BinarySearch(data,3)           // Prints 1
// BinarySearch returns 1 because data[1] <= 3 < data[2].
Make/O data = {9, 4, 3, -6}          // Monotonic decreasing
Print BinarySearch(data,2.5)         // Prints 2
// BinarySearch returns 2 because data[2] >= 2.5 > data[3].
Print BinarySearch(data,10)          // Prints -1, precedes first value
Print BinarySearch(data,-99)         // Prints -2, beyond last value
```

See Also

The **BinarySearchInterp** and **FindLevel** operations. See **Indexing and Subranges** on page II-95.

BinarySearchInterp

BinarySearchInterp(*waveName, val*)

The BinarySearchInterp function performs a binary interpolated search of the named wave for the value *val*. The returned value, pt, is a floating-point point index into the named wave such that *waveName*[pt] == *val*.

Details

BinarySearchInterp is useful for finding the point in an XY pair that corresponds to a particular X coordinate.

WaveName must contain monotonically increasing or decreasing values.

When the named wave does not actually contain the value *val*, BinarySearchInterp locates a value below *val* and a value above *val* and uses reverse linear interpolation to figure out where *val* would fall if a straight line were drawn between them. It includes that fractional amount in the resulting point index.

BinarySearchInterp returns NaN if *val* is not within the range of values in the wave.

Examples

```
Make/O data = {1, 2, 3.3, 4.9}          // Monotonic increasing
Print BinarySearchInterp(data,3)        // Prints 1.76923
Print data[1.76923]                     // Prints 3
Make/O data = {9, 4, 3, 1}              // Monotonic decreasing
Print BinarySearchInterp(data,2.5)      // Prints 2.25
Print data[2.25]                        // Prints 2.5
```

See Also

The **BinarySearch** and **FindLevel** operations. See **Indexing and Subranges** on page II-95.

binomial

binomial(*n, k*)

The binomial function returns the ratio:

$$\frac{n!}{k!(n-k)!}.$$

It is assumed that n and k are integers and $0 \le k \le n$ and ! denotes the factorial function.

Note that although the binomial function is an integer-valued function, a double-precision number has 53 bits for the mantissa. This means that numbers over 2^{52} (about 4.5×10^{15}) will be accurate to about one part in 2×10^{16}.

binomialln

binomialln(*a, b*)

The binomialln function returns the natural log of the binomial coefficient for *a* and *b*.

$$\text{binomialln}(a,b) = \ln(a!) - \ln(b!) - \ln((a-b)!)$$

See Also

Chapter III-12, **Statistics** for an overview of the various functions and operations; **binomial**, **StatsBinomialPDF**, **StatsBinomialCDF**, and **StatsInvBinomialCDF**.

binomialNoise

binomialNoise(*n, p*)

The binomialNoise function returns a pseudo-random value from the binomial distribution

$$f(x) = \binom{n}{x} p^x (1-p)^{n-x}, \qquad \begin{matrix} 0 \le p \le 1 \\ x = 1,2,...n \end{matrix}$$

whose mean is *np* and variance is *np*(1-*p*).

When *n* is large such that p^n is zero to machine accuracy the function returns NaN. When *n* is large such that *np*(1-*p*)>5 and 0.1<*p*<0.9 you can replace the binomial variate with a normal variate with mean *np* and standard deviation sqrt(*n***p**(1-*p*)).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat the same sequence. For repeatable "random" numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

The **SetRandomSeed** operation.

Noise Functions on page III-332.

Chapter III-12, **Statistics** for an overview of the various functions and operations.

boundingBall

boundingBall [/F/Z] *tripletWave*

The boundingBall operation calculates a bounding sphere for a set of X, Y, Z triplets. This operation accepts waves that have three or more columns; data in any additional columns are ignored.

Parameters

tripletWave is a three-column two-dimensional wave with X coordinates in column 0, Y in column 1, and Z in column 2.

Flags

/F Uses the algorithm from "An Efficient Bounding Sphere" by Jack Ritter in *Graphics Gems*. This algorithm is less accurate but it produces a ball that is sufficiently large to contain all the points.

/Z No error reporting.

Details

The center and radius of the bounding sphere are stored in the variables: V_CenterX, V_CenterY, V_CenterZ, and V_Radius.

If you are not using the /F flag, the operation also accepts a 2 column wave consisting of X, Y pairs for calculating the center and radius of a bounding circle in the plane.

References

Glassner, Andrew S., (Ed.), *Graphics Gems*, 833 pp., Academic Press, San Diego, 1990.

break

break

The break flow control keyword immediately terminates execution of a loop, switch, or strswitch. Execution then continues with code following the loop, switch, or strswitch.

See Also

Break Statement on page IV-37, **Switch Statements** on page IV-34, and **Loops** on page IV-36 for usage details.

BrowseURL

BrowseURL [**/Z**] ***urlStr***

The BrowseURL operation opens the Web browser or FTP browser on your computer and asks it to display a particular Web page or to connect to an FTP server.

BrowseURL sets a variable named V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if an error occurs.

Parameters

urlStr specifies a Web page or FTP server directory to be browsed. It is constructed of a naming scheme (e.g., "http://" or "ftp://"), a computer name (e.g., "www.wavemetrics.com" or "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/Test/TestFile1.txt"). See **Examples** for sample usage.

Flags

/Z Errors are not fatal. Will not abort procedure execution if the URL is bad or if the server is down. Your procedure can inspect the V_flag variable to see if the transfer succeeded. V_flag will be zero if it succeeded or nonzero if it failed.

Syntactic errors, such as omitting the URL altogether or omitting quotes, are still fatal.

Examples

```
// Browse a Web page.
    String url = "http://www.wavemetrics.com/News/index.html"
    BrowseURL url

// Browse an FTP server.
    String url = "ftp://ftp.wavemetrics.com/pub/test"
    BrowseURL url
```

BuildMenu

BuildMenu ***menuNameStr***

The BuildMenu operation rebuilds the user-defined menu items in the specified menu the next time the user clicks in the menu bar.

Parameters

menuNameStr is a string expression containing a menu name or "All".

Details

Call BuildMenu when you've defined a custom menu using string variables for the menu items. After you change the string variables, call BuildMenu to update the menu.

In Igor 6.22 or later, BuildMenu "All" rebuilds all the menu items and titles and updates the menu bar. In earlier versions of Igor it just rebuilds all user-defined menu items.

Under the current implementation, if menuNameStr is not "All", Igor will rebuild *all* user-defined menu items if BuildMenu is called for *any* user-defined menu.

See Also

Dynamic Menu Items on page IV-109.

Button

Button [**/Z**] ***ctrlName*** [***keyword = value*** [**,** ***keyword = value*** …]]

The Button operation creates or modifies the named button control.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

name is the name of the Button control to be created or changed.

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind=default:Appearance determined by **DefaultGUIControls**.

kind=native:Creates standard-looking controls for the current computer platform.

kind=os9:Igor Pro 5 appearance (quasi-Macintosh OS 9 controls that look the same on Macintosh and Windows).

platform=Mac:Changes the appearance of controls only on Macintosh; affects the experiment whenever it is used on Macintosh.

platform=Win:Changes the appearance of controls only on Windows; affects the experiment whenever it is used on Windows.

platform=All:Changes the appearance on both Macintosh and Windows computers.

disable=*d*

Sets the state of the control. *d* is a bit field: bit 0 (the least significant bit) is set when the control is hidden. Bit 1 is set when the control is disabled:

d=0: Normal (visible), enabled.

d=1: Hidden.

d=2: Visible and disabled. Drawn in grayed state, also disables action procedure.

d=3: Hidden and disabled.

See the **ModifyControl** example for setting the bits individually.

fColor=(*r*,*g*,*b*)

Sets color of the button. *r*, *g*, and *b* are integers from 0 to 65535. To set the color of the title text, use escape sequences as described below for title. fColor defaults to black (0,0,0). To set the color of the title text, see valueColor.

font="*fontName*"

Sets button font, e.g., `font="Helvetica"`.

fsize=*s*

Sets font size.

fstyle=*fs*

Specifies the font style. *fs* is a binary coded number with each bit controlling one aspect of the font style:

bit 0: Sold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

help={*helpStr*}

Specifies the help for the control. Help text is limited to a total of 255 characters. On Macintosh, help appears if you turn Igor Tips on. On Windows, help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "`\r`" in a quoted string.

noproc

No procedure is executed when clicking the button.

picture= *pict*

Draws the button using the named picture. The picture is taken to be three side-by-side frames that show the control appearance in the normal state, when the mouse is down, and in the disabled state. The picture may be either a global (imported) picture or a Proc Picture (see **Proc Pictures** on page IV-43). The size keyword is ignored when a picture is used.

pos={*left*,*top*}

Sets the position of the button in pixels.

pos+={*dx*,*dy*}

Offsets the position of the button in pixels.

proc=*procName*

Names the procedure to execute when clicking the button.

rename=*newName*

Gives the button a new name.

size={*width*,*height*}

Sets *width* and *height* of button in pixels.

title=*titleStr*

Sets title of button (text that appears in the button) to the specified string expression. If not given then title will be "New". If you use `""` the button will contain no text.

titleStr can contain formatting escape codes in order to create fancy, styled results. The escape codes are the same as used by the **TextBox** operation. The easiest way to generate fancy text is to create a dummy TextBox, set up the text as desired, click the To Cmd Line button, and then edit the TextBox command for use with the control.

userdata(*UDName*)=*UDStr*

Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

userdata(*UDName*)+=*UDStr*
: Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

valueColor=(*r*,*g*,*b*)
: Sets initial color of the button's text (title). *r*, *g*, and *b* range from 0 to 65535. valueColor defaults to black (0,0,0). To further change the color of the title text, use escape sequences as described for title=*titleStr*.

win=*winName*
: Specifies which window or subwindow contains the named button control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The action procedure, which may be a function *or* a macro, has the format:

```
Function procName(ctrlName) : ButtonControl
   String ctrlName
   …
End
```

The "`: ButtonControl`" designation tells Igor to include this procedure in the Procedure pop-up menu in the Button Control dialog.

The action procedure for a Button control can also use a predefined structure `WMButtonAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a Button control, otherwise it will use the old-style method.

A Button action procedure using a structure has the format:

```
Function newActionProcName(B_Struct) : ButtonControl
   STRUCT WMButtonAction &B_Struct
   …
End
```

For a Button control, the `WMButtonAction` structure has members as follows:

`WMButtonAction` Structure Members

Member	Description
`char ctrlName[MAX_OBJ_NAME+1]`	Control name.
`char win[MAX_WIN_PATH+1]`	Host (sub)window.
`STRUCT Rect winRect`	Local coordinates of host window.
`STRUCT Rect ctrlRect`	Enclosing rectangle of the control.
`STRUCT Point mouseLoc`	Mouse location.
`Int32 eventCode`	Event that executed the procedure.

`eventCode`	Event
-1	Control being killed
1	Mouse down
2	Mouse up
3	Mouse up outside control
4	Mouse moved
5	Mouse enter
6	Mouse leave

Events 2 and 3 only happen after event 1. Events 4, 5, and 6 happen only when mouse is over the control but happen regardless of the mouse button state.

WMButtonAction Structure Members

Member	Description
`Int32 eventMod`	Bitfield of modifiers. See **Control Structure eventMod Field** on page III-385.
`String userData`	Primary (unnamed) user data. If this changes, it is written back automatically.
`Int32 blockReentry`	Prevents reentry of control action procedure. See **Control Structure blockReentry Field** on page III-386.

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

ButtonControl

ButtonControl

ButtonControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined button control. See **Procedure Subtypes** on page IV-179 for details. See **Button** for details on creating a button control.

cabs

cabs(*z*)

The cabs function returns the real-valued absolute value of complex number *z*.

See Also

The **magsqr** function.

CaptureHistory

CaptureHistory(*refnum, stopCapturing*)

The CaptureHistory function returns a string containing text from the History window since a matching call to the **CaptureHistoryStart** function.

Parameters

refnum is a number returned from a call to CaptureHistoryStart. It identifies the starting point in the history for the returned string.

Set *stopCapturing* to nonzero to indicate that no more history should be captured for the given refnum. Subsequent calls to CaptureHistory with the same *refnum* will result in an error.

Set *stopCapturing* to zero to retrieve history text captured so far. Further calls to CaptureHistory with the same reference number will return this text, plus any additional history text added subsequently.

Details

You can have multiple captures active at one time. Each call to CaptureHistoryStart will return a unique reference number identifying a start point in the history. The capture corresponding to each reference number can be terminated at any time, regardless of the order of the CaptureHistoryStart calls.

CaptureHistoryStart

CaptureHistoryStart()

The CaptureHistoryStart function returns a reference number to identify a starting point in the History window text. Subsequently, the CaptureHistory function can be used to retrieve captured history text. See **CaptureHistory** for details.

catch

catch

The catch flow control keyword defines the beginning of code in a try-catch-entry flow control construct for handling any abort conditions.

See Also

The **try-catch-endtry** flow control statement for details.

cd

cd *dataFolderSpec*

The cd operation sets the current data folder to the specified data folder. It is identical to the longer-named SetDataFolder operation.

cd is named after the UNIX "change directory" command.

See Also

SetDataFolder, **pwd**, **Dir**, **Data Folders** on page II-121

ceil

ceil(*num*)

The ceil function returns the closest integer greater than or equal to *num*.

See Also

The **round**, **floor**, and **trunc** functions.

cequal

cequal(*z1, z2*)

The cequal function determines the equality of two complex numbers *z1* and *z2*. It returns 1 if they are equal, or 0 if not.

This is in contrast to the == operator, which compares only the real components of *z1* and *z2*, ignoring the imaginary components.

Examples

```
Function TestComplexEqualities()
   Variable/C z1= cmplx(1,2), z2= cmplx(1,-2)
   // This test compares only the real parts of z1 and z2:
   if( z1 == z2 )
      Print "== match"
   else
      Print "no == match"
   endif
   // This test compares both real and imaginary parts of z1 and z2:
   if( cequal(z1,z2) )
      Print "cequal match"
   else
      Print "no cequal match"
   endif
End
```

```
•TestComplexEqualities()
  == match
  no cequal match
```

See Also

The **imag**, **real**, and **cmplx** functions.

char2num

char2num(*str*)

The char2num function returns a number which is the numeric representation of the first byte in the string expression *str*.

The char2num function treats *str* as a string of signed bytes. Consequently it returns a negative number for bytes that have bit 7 set. You can obtain the byte value as a positive number by ANDing with 0xFF.

Examples

```
Print char2num("A")           // Prints 65
Print char2num("ABC")         // Prints 65
Print char2num("•")           // Prints character code as negative number
Print char2num("•") & 0xFF    // Prints character code as positive number
Printf "%02X\r", char2num("•") & 0xFF   // Prints as hexadecimal
```

See Also

The **num2char**, **str2num** and **num2str** functions.

Chart

Chart [**/Z**] ***ctrlName*** [***keyword = value*** [**,** ***keyword = value*** **…**]]

The Chart operation creates or modifies a chart control. Charts are generally used in conjunction with data acquisition. Charts do not have to be connected to a FIFO, but they are not useful until they are.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the Chart control to be created or changed.

The following keyword=value parameters are supported:

chans={*ch#*, *ch#*,…} List of FIFO channel numbers that Chart is to monitor.

color(*ch#*)=(*r*,*g*,*b*) Sets the color of the specified trace. *r*, *g*, and *b* specify the amount of red, green, and blue in the color as an integer from 0 to 65535.

ctab=*colortableName* When a channel is connected to an image strip FIFO channel, the data is displayed as an image using this built-in color table. Valid names are the same as used in images. Invalid name will result in the default Grays color table being used.

disable=*d* Sets user editability of the control.

- *d*=0: Normal.
- *d*=1: Hide.
- *d*=2: Disable user input. Charts do not change appearance because they are read-only. When disabled, the hand cursor is not shown.

fbkRGB=(*r*,*g*,*b*) Sets frame background color. *r*, *g* and *b* are integers from 0 to 65535.

fgRGB=(*r*,*g*,*b*) Sets foreground color (text, etc.). *r*, *g* and *b* are integers from 0 to 65535

fifo=*FIFOName* Sets which named FIFO the chart will monitor. See the **NewFIFO** operation.

font="*fontName*" Sets the font used in the chart, e.g., `font="Helvetica"`.

fsize=*s* Sets font size for chart.

fstyle=*fs* Specifies the font style. *fs* is a binary coded number with each bit controlling one aspect of the font style as follows:

- bit 0: Bold.
- bit 1: Italic.
- bit 2: Underline.
- bit 3: Outline (*Macintosh only*).
- bit 4: Shadow (*Macintosh only*).

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

gain(*ch#*)=*g* Sets the display gain *g* of the specified channel relative to nominal. Values greater than unity expand the display.

gridRGB=(*r*,*g*,*b*) Sets grid color. *r*, *g*, and *b* are integers from 0 to 65535.

help={*helpStr*} Specifies help for the control. Help text is limited to a total of 255 characters. On Macintosh, help appears if you turn Igor Tips on. On Windows, help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.

jumpTo=*p* Jumps to point number *p*. This works in review mode only.

lineMode(*ch#*)=*lm* Sets the display line mode for the given channel.

lm=0: Dots mode. Draws values as dots. However, if the number of dots in a strip exceeds maxDots then Igor draws a vertical line from the min to the max of the values packed into the strip.

lm=1: Lines mode. Draws a vertical line encompassing the min and the max of the points in a given strip along with the last point of the preceding strip. Since which strip is the preceding strip depends on the direction of motion then the appearance may slightly shift depending on which direction the chart is moving.

lm=2: Sticks to zero mode. Draws a vertical line encompassing the min and the max of the points in a given strip along with a value of zero.

mass=*m* Sets the "feel" of the chart paper when you move it with the mouse. The larger the mass *m*, the slower the chart responds. Odd values cause the movement of the paper to stop the instant the mouse is clicked while even values continue with the illusion of mass.

maxDots=*md* Controls whether points in a given vertical strip of the chart are displayed as dots or as a solid line. See lineMode above. Default is 20.

offset(*ch#*)=*o* Sets the display offset of the specified channel. The offset value *o* is subtracted from the data before the gain is applied.

oMode=*om* Chart operation mode.

om=0: Live mode.

om=1: Review mode.

pbkRGB=(*r*,*g*,*b*) Sets plot area background color. *r*, *g*, and *b* are integers from 0 to 65535.

ppStrip=*pps* Number of data points packed into each vertical strip of the chart.

rSize(*ch#*)=*rs* Sets the relative vertical size allocated to the given channel. Nominal is unity. If the value of *rs* is zero then this channel shares space with the previous channel.

sMode=*sm* Status line mode.

sm=0: Turns off fancy status line and positioning bar.

sm=1: Normal mode.

sm=2: Uses alternate style for bar.

sRate=*sr* Sets the scroll rate (vertical strips/second). If the chart control is in review mode negative numbers scroll in reverse.

title=*titleStr* Specifies the chart title. Use "" for no title.

uMode=*um* Selects the update mode.

um=1: Fast update with no bells and whistles.

um=2: Status line and positioning bar.

um=3: Status line, positioning bar, and animated pens.

win=*winName* Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The action of some of the Chart keywords depends on whether or not data acquisition is taking place. If the chart is in review mode then all keywords cause the chart to be redrawn. If data acquisition is taking place and the chart is in live mode then some keywords affect new data but do not attempt to update the part of the "paper" that has already been drawn. The following keywords affect only new data during live mode:

```
ppStrip  maxDots  gain  offset  color  lineMode
```

See Also

Charts on page III-360 and **FIFOs and Charts** on page IV-276.

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

chebyshev

chebyshev(*n*, *x*)

The chebyshev function returns the Chebyshev polynomial of the first kind and of degree *n*.

The Chebyshev polynomials satisfy the recurrence relation:

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x) \text{ with: } T_0(x) = 1 \quad .$$
$$T_1(x) = x$$
$$T_2(x) = 2x^2 - 1$$

The orthogonality of the polynomial is expressed by the integral:

$$\int_{-1}^{1} \frac{T_n(x)T_m(x)}{\sqrt{1-x^2}}dx = \begin{cases} 0 & m \neq n \\ \pi/2 & m = n \neq 0 \\ \pi & m = n = 0 \end{cases} .$$

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

See Also

chebyshevU.

chebyshevU

chebyshevU(*n*, *x*)

The chebyshevU function returns the Chebyshev polynomial of the second kind, degree *n* and argument *x*.

The Chebyshev polynomial of the second kind satisfies the recurrence relation

```
U(n+1,x)=2xU(n,x)-U(n-1,x)
```

which is also the recurrence relation of the Chebyshev polynomials of the first kind.

The first 10 polynomials of the second kind are:

```
U(0,x)=1
U(1,x)=2x
U(2,x)=4x^2-1
U(3,x)=8x^3-4x
U(4,x)=16x^4-12x^2+1
U(5,x)=32x^5-32x^3+6x
U(6,x)=64x^6-80x^4+24x-1
U(7,x)=128x^7-192x^5+80x^3-8x
U(8,x)=256x^8-448x^6+240x^4-40x^2+1
U(9,x)512x^9-1024x^^7+672x^5-160x^3+10x
```

See Also

The **chebyshev** function.

CheckBox

CheckBox [**/Z**] ***ctrlName*** [***keyword = value*** [**,** ***keyword = value*** **…**]]

The CheckBox operation creates or modifies a checkbox, radio button or disclosure triangle in the target or named window, which must be a graph or control panel.

ctrlName is the name of the checkbox.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the CheckBox control to be created or changed.

The following keyword=value parameters are supported:

appearance={*kind* [, *platform*]}
: Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

  kind can be one of `default`, `native`, or `os9`.

  platform can be one of `Mac`, `Win`, or *All*.

  See **Button** and **DefaultGUIControls** for more appearance details.

disable=*d*
: Sets user editability of the control.

  d=0: Normal.

  d=1: Hide.

  d=2: Disable user input.

fsize=*s*
: Sets font size for checkbox.

fColor=(*r*,*g*,*b*)
: Sets the initial color of the title. *r*, *g*, and *b* range from 0 to 65535. fColor defaults to black (0,0,0). To further change the color of the title text, use escape sequences as described for title=*titleStr*.

help={*helpStr*}
: Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "`\r`" in a quoted string.

mode=*m*
: Specifies checkbox appearance.

  m=0: Default checkbox appearance.

  m=1: Display as a radio button control.

  m=2: Display as a disclosure triangle (*Macintosh*) or treeview expansion node (*Windows*).

noproc
: Specifies that no procedure is to execute when clicking the checkbox.

picture= *pict*
: Draws the checkbox using the named picture. The picture is taken to be six side-by-side frames which show the control appearance in the normal state, when the mouse is down, and in the disabled state. The first three frames are used when the checked state is false and the next three show the true state. The picture may be either a global (imported) picture or a Proc Picture (see **Proc Pictures** on page IV-43).

pos={*left*,*top*}
: Sets the position of the checkbox in pixels.

pos+={*dx*,*dy*}
: Offsets the position of the checkbox in pixels.

proc=*procName*
: Specifies the procedure to execute when the checkbox is clicked.

rename=*newName*
: Renames the checkbox to *newName*.

side=s
: s =0: Checkbox is on the left, title is on the right (default).

  s =1: Checkbox is on the right, title is on the left.

size={*width*,*height*}
: Sets checkbox size in pixels.

title=*titleStr*
: Sets title of checkbox to the specified string expression. The title is the text that appears in the checkbox. If not given or if `""` then the title will be "New".

  titleStr can contain formatting escape codes in order to create fancy, styled results. The escape codes are the same as used by the **TextBox** operation. The easiest way to

generate fancy text is to make selections from the Insert popup in the Checkbox Control dialog.

userdata(*UDName*)=*UDStr*
: Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

userdata(*UDName*)+=*UDStr*
: Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

value=*v*
: Specifies whether the checkbox is selected (*v*=1) or not (*v*=0).

variable= *varName*
: Specifies a global numeric variable to be set to the current state of a checkbox whenever it is clicked or when it is set by the value parameter. The variable is two-way: setting the variable also changes the state of the checkbox.

win=*winName*
: Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

  When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The action procedure, which may be a function *or* a macro, has the format:

```
Function procName(ctrlName,checked) : CheckBoxControl
   String ctrlName
   Variable checked       // 1 if selected, 0 if not
   …
End
```

The "`: CheckboxControl`" designation tells Igor to include this procedure in the Procedure pop-up menu in the Checkbox Control dialog.

The action procedure for a CheckBox control can also use a predefined structure `WMCheckboxAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a CheckBox control, otherwise it will use the old-style method.

A CheckBox action procedure using a structure has the format:

```
Function newActionProcName(CB_Struct) : CheckBoxControl
   STRUCT WMCheckboxAction &CB_Struct
   …
End
```

For a CheckBox control, the `WMCheckboxAction` structure has members as described in the following table:

`WMCheckboxAction` Structure Members

Member	Description
`char ctrlName[MAX_OBJ_NAME+1]`	Control name.
`char win[MAX_WIN_PATH+1]`	Host (sub)window.
`STRUCT Rect winRect`	Local coordinates of host window.
`STRUCT Rect ctrlRect`	Enclosing rectangle of the control.
`STRUCT Point mouseLoc`	Mouse location.
`Int32 eventCode`	Event that executed the procedure.

`eventCode`	Event
-1	Control being killed
2	Mouse up

WMCheckboxAction Structure Members

Member	Description
Int32 eventMod	Bitfield of modifiers. See **Control Structure eventMod Field** on page III-385.
String userData	Primary (unnamed) user data. If this changes, it is written back automatically.
Int32 blockReentry	Prevents reentry of control action procedure. See **Control Structure blockReentry Field** on page III-386.
Int32 checked	Checkbox state.

Action functions should respond only to documented eventCode values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

When using radio button controls, it is the responsibility of the Igor programmer to turn off other radio buttons when one of a group of radio buttons is pressed.

Examples

The following code is an example of how to program such a group. (Copy the following code into the procedure window of a new experiment and then bring up the panel.)

```
Window Panel0() : Panel
   PauseUpdate; Silent 1          // building window …
   NewPanel /W=(150,50,353,212)
   Variable/G gRadioVal= 1
   CheckBox check0,pos={52,25},size={78,15},title="Radio 1"
   CheckBox check0,value=1,mode=1,proc=MyCheckProc
   CheckBox check1,pos={52,45},size={78,15},title="Radio 2"
   CheckBox check1,value=0,mode=1,proc=MyCheckProc
   CheckBox check2,pos={52,65},size={78,15},title="Radio 3"
   CheckBox check2,value= 0,mode=1,proc=MyCheckProc
EndMacro

Function MyCheckProc(name,value)
   String name
   Variable value

   NVAR gRadioVal= root:gRadioVal

   strswitch (name)
      case "check0":
         gRadioVal= 1
         break
      case "check1":
         gRadioVal= 2
         break
      case "check2":
         gRadioVal= 3
         break
   endswitch
   CheckBox check0,value= gRadioVal==1
   CheckBox check1,value= gRadioVal==2
   CheckBox check2,value= gRadioVal==3
End
```

See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

CheckBoxControl

CheckBoxControl

CheckBoxControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined checkbox control. See **Procedure Subtypes** on page IV-179 for details. See **CheckBox** for details on creating a checkbox control.

CheckDisplayed

CheckDisplayed [/A/W] *waveName* [, *waveName*]…

The CheckDisplayed operation determines if named waves are displayed in a host window or subwindow.

Flags

/A	Checks all graph and table windows
/W=*winName*	Checks only the named graph or table window When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

If neither /A nor /W are used, CheckDisplayed checks only the top graph or table.

CheckDisplayed sets a bit in the variable V_flag for each wave that is displayed.

Examples

```
CheckDisplayed/W=Graph0 aWave,bWave,cWave
```

Checks Graph0 to see if aWave, bWave, and cWave are displayed in it. If aWave is displayed, CheckDisplayed sets bit 0 of V_flag (V_flag=1). If bWave is displayed, sets bit 1 (V_flag=2). If cWave is displayed, sets bit 2 (V_flag=4). If all three waves are displayed, V_flag=7.

See Also

Setting Bit Parameters on page IV-12 for information about bit settings.

CheckName

CheckName(*nameStr*, *objectType* [, *windowNameStr*])

The CheckName function returns a number which indicates if the specified name is legal and unique among objects in the namespace of the specified object type.

Waves, global numeric variables, and global string variables are all in the same namespace and need to be unique only within the data folder containing them. However, they also need to be distinct from names of Igor operations and functions and from names of user-defined procedures.

Data folders are in their own namespace and need to be unique only among other data folders at the same level of the data folder hierarchy.

windowNameStr is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of *objectType*.

Details

A result of zero indicates that the name is legal and unique within its namespace. Any nonzero result indicates that the name is illegal or not unique. You can use the **CleanupName** and **UniqueName** functions to guarantee legality and uniqueness.

nameStr should contain an unquoted name (i.e., no single quotes for liberal names), such as you might receive from the user through a dialog or control panel.

objectType is one of the following:

1: Wave.
2: Reserved.
3: Global numeric variable.
4: Global string variable.
5: XOP target window (e.g., surface plot).
6: Graph window.
7: Table window.
8: Layout window.
9: Control panel window.
10: Notebook window.
11: Data folder.
12: Symbolic path.
13: Picture.
14: Annotation in the named or topmost graph or layout.
15: Control in the named topmost graph or panel.
16: Notebook action character in the named or topmost notebook.

The *windowNameStr* argument is used only with *objectTypes* 14, 15, and 16. The *nameStr* is checked for uniqueness only within the named window (other windows might have objects with the given name). If a named window is given but does not exist, any valid *nameStr* is permitted

Examples

```
Variable waveNameIsOK = CheckName(proposedWaveName, 1) == 0
Variable annotationNameIsOK = CheckName("text0", 14, "Graph0")
```

See Also

CleanupName and **UniqueName** functions.

ChildWindowList

ChildWindowList(*hostNameStr*)

The ChildWindowList function returns a string containing a semicolon-separated list of immediate subwindow window names of the specified host window or subwindow.

Parameters

hostNameStr is a string or string expression containing the name of an existing host window or subwindow.

When identifying a subwindow with *hostNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

Error if the host does not exist or if it is not an allowed host type.

See Also

WinList and **WinType** functions.

ChooseColor

ChooseColor [**/C=(*r*,*g*,*b*)**]

The ChooseColor operation displays a dialog for choosing a color.

The color initially shown is black unless you specify a different color with /C.

Flags

/C=(*r*,*g*,*b*) *r*, *g*, and *b* specify the amount of red, green, and blue in the color initially displayed in the dialog as an integer from 0 to 65535.

Details

ChooseColor sets the variable V_flag to 1 if the user clicks OK in the dialog or to 0 otherwise.

If V_flag is 1 then V_Red, V_Green, and V_Blue are set to the selected color as integers from 0 to 65535.

See Also

ImageTransform rgb2hsl and **hsl2rgb**.

CleanupName

CleanupName(*nameStr, beLiberal*)

The CleanupName function returns the input name string, possibly altered to make it a legal object name.

Details

nameStr should contain an unquoted (i.e., no single quotes for liberal names) name, such as you might receive from the user through a dialog or control panel.

beLiberal is 0 to use strict name rules or 1 to use liberal name rules. Strict rules allow only letters, digits and the underscore character. Liberal rules allow other characters such as spaces and dots. Liberal rules were introduced with Igor Pro 3.0 and are allowed for names of waves and data folders only.

Note that a cleaned up name is not necessarily unique. Call **CheckName** to check for uniqueness or **UniqueName** to ensure uniqueness.

Examples

```
String cleanStrVarName = CleanupName(proposedStrVarName, 0)
```

See Also

CheckName and **UniqueName** functions.

Close

Close [/A] *fileRefNum*

The Close operation closes a file previously opened by the **Open** operation or closes all such files if /A is used.

Parameters

fileRefNum is the file reference number of the file to close. This number comes from the Open operation. If /A is used, *fileRefNum* should be omitted.

Flags

/A Closes all files. Mainly useful for cleaning up after an error during procedure execution occurs so that the normal Close operation is never executed.

CloseMovie

CloseMovie

The CloseMovie operation closes the currently open movie. You must close a movie before you can play it.

See Also

The **NewMovie** operation.

CloseProc

CloseProc /NAME=*procNameStr* [*flags*]

CloseProc /FILE=*fileNameStr* [*flags*]

The CloseProc operation closes a procedure window. You cannot call CloseProc on the main Procedure window.

CloseProc provides a way to programmatically create and alter procedure files. You might do this in order to make a user-defined menu-bar menu with contents that change.

Note: CloseProc alters procedure windows so it cannot be called while functions or macros are running. If you want to call it from a function or macro, use **Execute/P**.

Warning: If you close a procedure window that has no source file or without specifying a destination file, the window contents will be permanently lost.

Flags

/COMP[=*compile*] Specifies whether procedures should be compiled after closing the procedure window.

compile=1: Compiles procedures (same as /COMP only).

compile=0: Leaves procedures in an uncompiled state.

/D[=*delete*] Specifies whether the procedure file should be deleted after closing the procedure window.

delete=1: Deletes procedure file (same as /D only). **Warning**: You cannot recover any file deleted this way.

delete=0: Leaves any associated file unaffected.

/FILE=*fileNameStr* Identifies the procedure window to close using the file name and path to the file given by *fileNameStr*. The string can be just the file name if /P is used to specify a symbolic path name of the enclosing folder. It can be a partial path if /P points to a folder enclosing the start of the partial path. It can also be a full path the file.

/NAME=*procNameStr*

Identifies the procedure window to close with the string expression *procNameStr*. This is the same text that appears in the window title. If the procedure window is associated with a file, it will be the file name and extension.

/P=*pathname* Specifies the folder to look in for the file specified by /FILE. *pathName* is the name of an existing symbolic path.

/SAVE[=*savePathStr*]

Saves the procedure before closing the window. If the flag is used with no argument, it saves any changes to the procedure window to its source file before closing it. If *savePathStr* is present, it must be a full path naming a file in which to save the procedure window contents. The /P flag is not used with *savePathStr* so it must be a full path.

Details

Specify which window to close using either the /NAME or /FILE flag. You must use one or the other. Usually you would use /NAME, as it is usually more convenient. If by some chance two procedures have the same name, /FILE can be used to distinguish between them.

You cannot call CloseProc on a nonmain procedure window that someone has had the bad taste to call "Procedure".

See Also

Chapter III-13, **Procedure Windows**.

The **Execute/P** operation.

cmplx

cmplx(*realPart*, *imagPart*)

The cmplx function returns a complex number whose real component is *realPart* and whose imaginary component is *imagPart*.

Use this to assign a value to a complex variable or complex wave.

Examples

Assume wave1 is complex. Then:

```
wave1(0) = cmplx(1,2)
```

sets the Y value of wave1 at x=0 such that its real component is 1 and its imaginary component is 2.

Assuming wave2 and wave3 are real, then:

```
wave1 = cmplx(wave2,wave3)
```

sets the real component of wave1 equal to the contents of wave2 and the imaginary component of wave1 equal to the contents of wave3.

You may get unexpected results if the number of points in wave2 or wave3 differs from the number of points in wave1. If wave2 or wave3 are shorter than wave1, the last element of the short wave is copied repeatedly to fill wave1.

See Also

conj, **imag**, **magsqr**, **p2rect**, **r2polar**, and **real** functions.

cmpstr

cmpstr(*str1*, *str2* [, *flags*])

The cmpstr function returns -1, 0 or 1 depending on how string *str1* compares alphabetically to string *str2*.

Details

cmpstr returns the following values:

-1:	*str1* is alphabetically before *str2*.
0:	*str1* and *str2* are equal.
1:	*str1* is alphabetically after *str2*.

If *flags* is not present, or if *flags* is zero, case (upper or lower) is not significant. Set *flags* to 1 for a case-sensitive comparison.

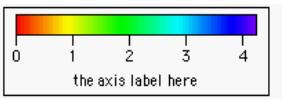
See Also

The **ReplaceString** function.

ColorScale

ColorScale [*flags*] [, *keyword = value*, …] [*axisLabelStr*]

The ColorScale operation puts a color scale (or "color legend") annotation on the top graph or page layout.



The ColorScale operation can be executed with no flags and no parameters.

When a graph is the top window the color scale represents the colors and values associated with the first image plot that was added to the graph.

If there is no image plot in the graph, the color scale represents the first contour plot or first f(z) trace added to the graph, one of which must exist for the command to execute without error when executed without parameters.

Executing ColorScale (with no parameters) when a layout is the top window displays a color bar as if the `ctab={0,100,Rainbow}` parameters had been specified.

Flags

Use the /W=*winName* flag to specify a specific graph or layout window. When used on the command line or in a Macro or Proc, /W must precede all other flags.

To change a color scale, use the /C/N=*name* flags. Annotations are automatically named "text0", "text1", etc. if no name is specified when it is created, and you must use that name to modify an existing annotation or else a new one will be created.

For explanations of all flags see the **TextBox** operation.

Parameters

The following keyword-value pairs are the important parameters to the ColorScale operation, because they specify what object the color scale is representing.

Note: For use with page layouts, the keyword ={*graphName*,…} form is required.

For graphs it is simpler to use the image=*imageInstanceName* form (omitting graphName), though you can use `$""` to mean the top graph, or specify the name of another graph with the long form. See the **Examples**.

axisLabelStr Contains the text printed beside the color scale's main axis. This text is interpreted the same way as for the **Label** operation. It may contain escape codes to alter the text color or display subscripts, for example. You can use **AppendText** or **ReplaceText** to modify this axis label string. The default value for axisLabelStr is `""`.

cindex=*cindexMatrixWave*

The colors shown are those in the named color index wave with axis values derived from the wave's X (row) scaling and units.

The image colors are determined by doing a lookup in the specified matrix wave. See the **ModifyImage cindex** keyword.

contour=*contourInstanceName*
contour={*graphName*,*contourInstanceName*}

The colors show the named contour plot's colors and associated contour (Z) values and contour data units. All of the image plot's characteristics are represented, including color table, cindex, and fixed colors.

ctab={*zMin*,*zMax*,*ctName*, *mode*}

The color table specified by *ctName* is drawn in the color legend. *ctName* can be any of those returned by the **CTabList** function, such as Grays or Rainbow. Also see **Color Tables** on page II-349.

The color table name can be omitted if you want to leave it unchanged. *zMin* and *zMax* set the range of Z values to map. Set parameter *mode* to 1 to reverse the color table; zero or missing value does not reverse the color table.

image=*imageInstanceName*
image={*graphName*,*imageInstanceName*}

The colors show the named image plot's colors and associated image (Z) values and image data units. All of the image plot's characteristics are represented, including color table, cindex, lookup wave, eval colors, and NaN transparency. **Note**: only false-color image plots can be used with ColorScale (see **Indexed Color Details** on page II-356).

lookup= *waveName* Specifies an optional 1D wave used to modify the mapping of scaled Z values into the color table specified with the ctab keyword. Values should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the image. Used to apply gamma correction to grayscale images or for special effects. Use `lookup=$""` to remove option.

This keyword is not needed with the image keyword, even if the image plot uses a lookup wave. The image plot's lookup wave is used instead of the ColorScale lookup wave.

trace=*traceInstanceName*
trace={*graphName*,*traceInstanceName*}

The colors show the color(s) of the named trace. This is useful when the trace has its

color set by a "Z wave" using the `ModifyGraph zColor(traceName)=...` feature. In the Modify Trace Appearance dialog this is selected in the "Set as f(z)" subdialog. The color scale's main axis shows the range of values in the Z wave, and displays any data units the wave may have.

Size Parameters

The following keyword-value parameters modify the size of the color scale annotation. These keywords are similar to those used by the **Slider** control. The size of the annotation is indirectly controlled by setting the size of the "color bar" and the various axis parameters. The annotation sizes itself to accommodate the color bar, tick labels, and axis label(s).

height=*h*
: Sets the height of the color bar in points, overriding any heightPct setting. The default height is 75% of the plot area height if the color scale is vertical, or a constant of 15 points if the color scale is horizontal. The default is restored by specifying `height=0`. Specifying a heightPct value resets height to this default.

heightPct=*hpct*
: Sets height as a percentage of the graph's plot area, overriding any height setting. The default height is 75% of the plot area height if the color scale is vertical, or a constant of 15 points if the color scale is horizontal. The default height is restored by setting heightPct=0. Specifying a height value resets heightPct to this default.

side=*s*
: Selects on which axis to draw main axis ticks.

  s=1: Right of the color bar if vert=1, or below if vert=0.

  s=2: Left of the color bar if vert=1, or above if vert=0.

vert=*v*
: Specifies color scale orientation.

  v=0: Horizontal.

  v=1: Vertical (default).

width=*w*
: Sets the width of the color bar in points, overriding any widthPct setting. The default width is a constant 15 points if the color scale is vertical, or 75% of the plot area width if the color scale is horizontal. The default is restored by specifying `width=0`. Specifying a widthPct value resets width to this default.

widthPct=*wpct*
: Sets width as a percentage of the graph's plot area, overriding any width setting. The default width is a constant 15 points if the color scale is vertical, or 75% of the plot area width if the color scale is horizontal. The default is restored by setting `widthPct=0`. Specifying a width value resets widthPct to this default.

Color Bar Parameters

The following keyword-value parameters modify the appearance of the color scale color bar.

colorBoxesFrame=*on*
: Draws frames surrounding up to 99 swatches of colors in the color bar (*on*=1).

  When specifying more than 99 colors in the color bar (such as the Rainbow color table, which has 100 colors), the boxes aren't framed. Framing color boxes is effective only for small numbers of colors. Set the width of the frame with the frame keyword.

  Use *on*=0 to turn off color box frames.

frame=*f*
: Specifies the thickness of the frame drawn around the color bar in points (*f* can range from 0 to 5 points). The default is 1 point. Fractional values are permitted.

  Turn frames off with *f*=0. Values less that 0.5 do not display on screen, but the thin frame will print.

frameRGB=(*r*, *g*, *b*) or 0
: Sets the color of the frame around the color bar. *r*, *g*, and *b* specify the amount of red, green, and blue as an integer from 0 to 65535. The frame includes the individual color bar colors when colorBoxesFrame=1.

  The frame will use the colorscale foreground color, as set by the /G flag, when frameRGB=0.

Axis Parameters

The following keyword-value parameters modify the appearance of the color scale axes. These keywords are based on the **ModifyGraph** Axis keywords because they modify the main or secondary color scale axes.

axisRange={*zMin*, *zMax*}
Sets the color bar axis range to values specified by *zMin* and *zMax*. Use * to use the default axis range for either or both values.

Omit *zMin* or *zMax* to leave that end of the range unchanged. For example, use {*zMin*, } to change *zMin* and leave *zMax* alone, or use { ,*} to set only the axis maximum value to the default value.

dateInfo={*sd*,*tm*,*dt*} Controls formatting of date/time axes.

sd=0: Show date in the date&time format.

sd=1: Suppress date.

tm=0: 12 hour (AM/PM) time.

tm=1: 24 hour (military) time.

tm=2: Elapsed time.

dt=0: Short dates (2/22/90).

dt=1: Long dates (Thursday, February 22, 1990).

dt=2: Abbreviated dates (Thurs, Feb 22, 1990).

These have no effect unless the axis is controlled by a wave with 'dat' data units.

For an f(z) color scale:

```
SetScale d, 0,0, "dat", fOfZWave
```

For a contour plot or image plot color scale:

```
SetScale d, 0,0, "dat", ZorXYZorImageWave
```

See **Date/Time Axes** on page II-276 and **Date, Time, and Date&Time Units** on page II-85 for details on how date/time axes work.

font=*fontNameStr* Name of font as string expression. If the font does not exist, the default font is used. Specifying "default" has the same effect. Unlike ModifyGraph, the *fontNameStr* is evaluated at runtime, and its absence from the system is not an error.

fsize=*s* Sets the font size in points.

s=0: Use the graph font size for tick labels and axis labels (default).

fstyle=*fs* Sets the font style. *fs* is a binary coded number with each bit controlling one aspect of the font style for the tick mark labels:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

bit 5: Condensed (*Macintosh only*).

bit 6: Extended (*Macintosh only*).

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

highTrip=*h* If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation. The default highTrip is 100,000.

lblLatPos=*p* Sets a lateral offset for the main axis label. This is an offset parallel to the axis. *p* is in points. Positive is down for vertical axes and to the right for horizontal axes. The default is 0.

lblMargin=*m* Moves the main axis label by *m* points (default is 0) from the normal position. The default value is -5, which brings the axis label closer to the axis. Use more positive values to move the axis label away from the axis.

lblRot=*r* Rotates the axis label by *r* degrees. *r* is a value from -360 to 360. Rotation is counterclockwise and starts from the label's normal orientation.

log=*l* Specifies the axis type.

l=0: Linear (default).

l=1: Log base 10.

l=2: Log base 2.

logHTrip=*h* Same as highTrip but for log axes. The default is 10,000.

logLTrip=*l* Same as lowTrip but for log axes. The default is 0.0001.

logTicks=*t* Specifies the maximum number of decades in log axis before minor ticks are suppressed.

lowTrip=*l* If the axis extrema are between its lowTrip and its highTrip, then tick mark labels use fixed point notation. Otherwise, they use exponential (scientific or engineering) notation. The default lowTrip is 0.1.

minor=*m*
- *m*=0: Disables minor ticks (default).
- *m*=1: Enables minor ticks.

notation=*n*
- *n*=0: Engineering notation (default).
- *n*=1: Scientific notation.

nticks=*n* Specifies the approximate number of ticks to be distributed along the main axis. Ticks are labelled using the same automatic algorithm used for graph axes. The default is 5.
- *n*=0: No ticks.

prescaleExp=*exp* Multiplies axis range by 10*exp* for tick labeling and *exp* is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. The default is 0 (no modification). See the discussion in the **ModifyGraph (axes) Details** section.

tickExp=*te*
- *te*=1: Forces tick labels to exponential notation when labels have units with a prefix.
- *te*=0: Turns off exponential notation.

tickLen=*t* Sets the length of the ticks. *t* is the major tick mark length in points. This value must be between -100 and 50.
- *t*=0 to 50: Draws tick marks between the tick labels and the colors box.
- *t*=-1: Default; auto tick length, equal to 70% of the tick label font size. Draws tick marks between the tick labels and the colors box.
- *t*=-2 to -50: Draws tick marks crossing the edge of the colors box nearest the tick labels. The actual total tick mark length is -*t*.
- *t*=-100 to -51: Draws tick marks inside the edge of the colors box nearest the tick labels. Actual tick mark length is -(*t*+50). For example, -58 makes in an inside tick mark that is 8 points long.

tickThick=*t* Sets the tick mark thickness in points (from 0 to 5 points). The default is 1 point. Fractional values are permitted.
- *t*=0: Turns tick marks off, but not the tick labels.

tickUnit=*tu* Turns on (*tu*=0) or off (*tu*=1) units labels attached to tick marks.

userTicks={*tvWave*,*tlblWave*}
Supplies user defined tick positions and labels for the main axis. *tvWave* contains the numeric tick positions while text wave *tlblWave* contains the corresponding labels.

The tick mark labels can be multiline and use styled text. For more details, see **Fancy Tick Mark Labels** on page II-312. Overrides normal ticking specified by nticks.

ZisZ=*z* *z* =1 labels the zero tick mark (if any) with the single digit "0" regardless of the number of digits used for other labels. Default is *z*=0.

Secondary Axis Parameters

axisLabel2=*axisLabelString2*
Axis label for the secondary axis. This axis label is drawn only if userTicks2 is in effect. Text after any `\r` character is ignored, as is the `\r` character. The default is `""`.

lblLatPos2=*p* Sets lateral offset for secondary axis labels. This is an offset parallel to the axis. *p* is in points. Positive is down for vertical axes and to the right for horizontal axes. The default is 0.

lblMargin2=*m* Specifies the distance in points (default 0) to move the secondary axis label from the position that would be normal for a graph. The default is value is -5, which brings the axis label closer to the axis. Use more positive values to move the axis label away from the axis.

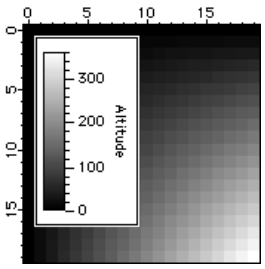
lblRot2=*r* Rotates the secondary axis label by *r* degrees counterclockwise starting from the normal label orientation. r is a value from -360 to 360.

userTicks2={*tvWave*,*tlblWave*}
Supplies user defined tick positions and labels for a second axis which is always on the

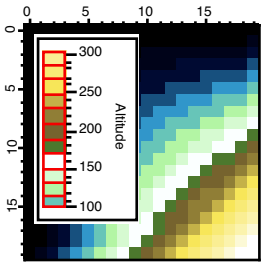
opposite side of the color bar from the main axis. The tick mark labels can be multiline and use styled text. For more details, see **Fancy Tick Mark Labels** on page II-312. This is the only way to draw a second axis.

Examples

```
Make/O/N=(20,20) img=p*q; NewImage img      // Make and display an image
ColorScale                                  // Create default color scale
// First annotation is text0
ColorScale/C/N=text0 nticks=3,minor=1,"Altitude"
```



```
ModifyImage img ctab= {*,*,Relief19,0}          // 19-color color table
ColorScale/C/N=text0 axisRange={100,300}        // Detail for 100-300 range
ColorScale/C/N=text0 colorBoxesFrame=1          // Frame the color boxes
ColorScale/C/N=text0 frameRGB=(65535,0,0)       // Red frame
```



See Also

For all other flags see the **TextBox** and **AppendText** operations.

ColorTab2Wave

ColorTab2Wave ***colorTableName***

The ColorTab2Wave operation extracts colors from the built-in color table and places them in an Nx3 matrix of red, green, and blue columns named M_colors. Values are unsigned 16-bit integers and range from 0 to 65535.

N will typically be 100 but may be as little as 9 and as large as 476. Use

```
Variable N= DimSize(M_colors,0)
```

to determine the actual number of colors.

The wave M_colors is created in the current data folder. Red is in column 0, green is in column 1, and blue in column 2.

Parameters

colorTableName can be any of those returned by **CTabList**, such as Grays or Rainbow.

colorTableName can also be `Igor` or `IgorRecent`, to return either the 128 standard or 0-32 user-selected colors from Igor's color menu.

Details

See **Color Tables** on page II-349.

Concatenate

Concatenate [***type flags***][***flags***] ***waveListStr, destWave***

Concatenate [***type flags***][***flags***] **{*wave1, wave2, wave3,…*}, *destWave***

The Concatenate operation combines data from the source waves into *destWave*, which is created if it does not already exist. If *destWave* does exists and overwrite is not specified, the source waves' data is concatenated with the existing data in the destination wave.

By default the concatenation increases the dimensionality of the destination wave if possible. For example, if you concatenate two 1D waves of the same length you get a 2D wave with two columns. The destination wave is said to be "promoted" to a higher dimensionality.

If you use the /NP (no promotion) flag, the dimensionality of the destination wave is not changed. For example, if you concatenate two 1D waves of the same length using /NP you get a 1D wave whose length is the sum of the lengths of the source waves.

If the source waves are of different lengths, no promotion is done whether /NP is used or not.

Parameters

waveListStr is a string expression containing a list of wave names separated by semicolons. The list must be terminated with a semicolon. The alternate syntax using {*wave1*, *wave2*, …} is limited to 100 waves or less, but there is no limit when using *waveListStr*.

destWave is the name of a new or existing wave that will contain the concatenation result.

Flags

/DL	Sets dimension labels. For promotion, it uses source wave names as new dimension labels otherwise it uses existing labels.
/KILL	Kills source waves.
/NP	Prevents promotion to higher dimension.
/NP=*dim*	Prevents promotion and appends data along the specified dimension (0= rows, 1= columns, 2=layers, 3=chunks). All dimensions other than the one specified by *dim* must be the same in all waves. Requires Igor Pro 6.12 or later.
/O	Overwrites *destWave*.

Type Flags *(used only in functions)*

Concatenate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-58 and **WAVE Reference Type Flags** on page IV-58 for a complete list of type flags and further details.

Details

If *destWave* does not already exist or, if the /O flag is used, *destWave* is created by duplication of the first source wave. Waves are concatenated in order through the list of source waves. If *destWave* exists and the /O flag is not used, then the concatenation starts with *destWave*.

destWave cannot be used in the source wave list.

Source waves must be either all numeric or all text.

If promotion is allowed, the number of low-order dimensions that all waves share in common determines the dimensionality of *destWave* so that the dimensionality of *destWave* will then be one greater. The default behaviors will vary according to the source wave sizes. Concatenating 1D waves that are all the same length will produce a 2D wave, whereas concatenating 1D waves of differing lengths will produce a 1D wave. Similarly, concatenating 2D waves of the same size will produce a 3D wave; but if the 2D source waves have differing numbers of columns then *destWave* will be a 2D wave, or if the 2D waves have differing numbers of rows then *destWave* will be a 1D wave. Concatenating 1D and 2D waves that have the same number of rows will produce a 2D wave, but when the number of rows differs, *destWave* will be a 1D wave. See the examples.

Use the /NP flag to suppress dimension promotion and keep the dimensionality of *destWave* the same as the input waves.

Examples

```
// Given the following waves:
Make/N=10 w1,w2,w3
Make/N=11 w4
Make/N=(10,7) m1,m2,m3
Make/N=(10,8) m4
Make/N=(9,8) m5

// Concatenate 1D waves
Concatenate/O {w1,w2,w3},wdest          // wdest is a 10x3 matrix
Concatenate {w1,w2,w3},wdest            // wdest is a 10x6 matrix
Concatenate/NP/O {w1,w2,w3},wdest       // wdest is a 30-point 1D wave
Concatenate/O {w1,w2,w3,w4},wdest       // wdest is a 41-point 1D wave

// Concatenate 2D waves
Concatenate/O {m1,m2,m3},wdest          // wdest is a 10x7x3 volume
Concatenate/NP/O {m1,m2,m3},wdest       // wdest is a 10x21 matrix
Concatenate/O {m1,m2,m3,m4},wdest       // wdest is a 10x29 matrix
Concatenate/O {m4,m5},wdest             // wdest is a 152-point 1D wave
Concatenate/O/NP=0 {m4,m5},wdest        // wdest is a 19x8 matrix

// Concatenate 1D and 2D waves
Concatenate/O {w1,m1},wdest             // wdest is a 10x8 matrix
Concatenate/O {w4,m1},wdest             // wdest is a 81-point 1D wave

// Append rows to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=0 {m6}, m7               // m7 is a 6x2 matrix

// Append columns to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=1 {m6}, m7               // m7 is a 3x4 matrix

// Append layer to 2D wave
Make/O/N=(3,2) m6, m7
Concatenate/NP=2 {m6}, m7               // m7 is a 3x2x2 volume
// The last command has the same effect as:
// Concatenate {m6}, m7
// Both versions extend add a third dimension to m7
```

conj

conj(*z*)

The conj function returns the complex conjugate of the complex value *z*.

See Also

cmplx, **imag**, **magsqr**, **p2rect**, **r2polar**, and **real** functions.

Constant

Constant *kName = literalNumber*

The Constant declaration defines the number *literalNumber* under the name *kName* for use by other code, such as in a switch construct.

See Also

The **Strconstant** keyword for string types, **Constants** on page IV-40 and **Switch Statements** on page IV-34.

continue

continue

The continue flow control keyword returns execution to the beginning of a loop, bypassing the remainder of the loop's code.

See Also

Continue Statement on page IV-38 and **Loops** on page IV-36 for usage details.

ContourInfo

ContourInfo(*graphNameStr, contourWaveNameStr, instanceNumber*)

The ContourInfo function returns a string containing a semicolon-separated list of information about the specified contour plot in the named graph.

Parameters

graphNameStr can be "" to refer to the top graph.

contourWaveNameStr is a string containing either the name of a wave displayed as a contour plot in the named graph, or a contour instance name (wave name with "#n" appended to distinguish the nth contour plot of the wave in the graph). You might get a contour instance name from the **ContourNameList** function.

If *contourWaveNameStr* contains a wave name, *instanceNumber* identifies which instance you want information about. *instanceNumber* is usually 0 because there is normally only one instance of a wave displayed as a contour plot in a graph. Set *instanceNumber* to 1 for information about the second contour plot of the wave, etc. If *contourWaveNameStr* is "", then information is returned on the *instanceNumber*th contour plot in the graph.

If *contourWaveNameStr* contains an instance name, and *instanceNumber* is zero, the instance is taken from *contourWaveNameStr*. If *instanceNumber* is greater than zero, the wave name is extracted from *contourWaveNameStr*, and information is returned concerning the *instanceNumber*th instance of the wave.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
DATAFORMAT	Either XYZ or Matrix.
LEVELS	A comma-separated list of the contour levels, including the final automatic levels, (or manual or from-wave levels), and the "more levels", all sorted into ascending Z order.
RECREATION	List of keyword commands as used by **ModifyContour** command. The format of these keyword commands is: ***keyword (x)=modifyParameters;***
TRACESFORMAT	The format string used to name the contour traces (see **AppendMatrixContour** or **AppendXYZContour**).
XAXIS	X axis name.
XWAVE	X wave name if any, else blank.
XWAVEDF	Full path to the data folder containing the X wave or blank if there is no X wave.
YAXIS	Y axis name.
YWAVE	Y wave name if any, else blank.
YWAVEDF	Full path to the data folder containing the Y wave or blank if there is no Y wave.
ZWAVE	Name of wave containing Z data from which the contour plot was calculated.
ZWAVEDF	Full path to the data folder containing the Z data wave.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the ";", prepend "ModifyContour", replace the "x" with the name of a contour plot ("data#1" for instance) and then **Execute** the resultant string as a command.

Examples

The following command lines create a very unlikely contour display. If you did this, you would most likely want to put each contour plot on different axes, and arrange the axes such that they don't overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack
Display;AppendMatrixContour jack
AppendMatrixContour/T/R jack         // Second instance of jack
```

This example accesses the contour information for the second contour plot of the wave "jack" (which has an instance number of 1) displayed in the top graph:

```
Print StringByKey("ZWAVE", ContourInfo("","jack",1))     // prints jack
```

See Also

The **Execute** and **ModifyContour** operations.

ContourNameList

ContourNameList(*graphNameStr, separatorStr*)

The ContourNameList function returns a string containing a list of contours in the graph window or subwindow identified by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

The parameter *separatorStr* should contain a single character such as "," or ";" to separate the names.

A contour name is defined as the name of the wave containing the data from which a contour plot is calculated, with an optional #n suffix that distinguishes between two or more contour plots in the same graph window that have the same wave name. Since the contour name has to be parsed, it is quoted if necessary.

Examples

The following command lines create a very unlikely contour display. If you did this, you would most likely want to put each contour plot on different axes, and arrange the axes such that they don't overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack,'jack # 2';
Display;AppendMatrixContour jack
AppendMatrixContour/T/R jack
AppendMatrixContour 'jack # 2'
AppendMatrixContour/T/R 'jack # 2'
Print ContourNameList("",";")
```

prints `jack;jack#1;'jack # 2';'jack # 2'#1;`

See Also

Another command related to contour plots and waves: **ContourNameToWaveRef**.

For commands referencing other waves in a graph: **TraceNameList**, **WaveRefIndexed**, **XWaveRefFromTrace**, **TraceNameToWaveRef**, **CsrWaveRef**, **CsrXWaveRef**, **ImageNameList**, and **ImageNameToWaveRef**.

ContourNameToWaveRef

ContourNameToWaveRef(*graphNameStr, contourNameStr*)

Returns a wave reference to the wave corresponding to the given contour name in the graph window or subwindow named by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

The contour name is identified by the string in *contourNameStr*, which could be a string determined using ContourNameList. Note that the same contour name can refer to different waves in different graphs, if the waves are in different data folders.

See Also

The **ContourNameList** function.

For a discussion of wave reference functions, see **Wave Reference Functions** on page IV-173.

ContourZ

ContourZ(*graphNameStr, contourInstanceNameStr, x, y* [,*pointFindingTolerance*])

The ContourZ function returns the interpolated Z value of the named contour plot data displayed in the named graph.

For gridded contour data, ContourZ returns the bilinear interpolation of the four surrounding XYZ values.

For XYZ triplet contour data, ContourZ returns the value interpolated from the three surrounding XYZ values identified by the Delaunay triangulation.

Parameters

graphNameStr can be "" to specify the topmost graph.

contourNameStr is a string containing either the name of the wave displayed as a contour plot in the named graph, or a contour instance name (wave name with "#n" appended to distinguish the nth contour plot of the wave in the graph). You might get a contour instance name from the **ContourNameList** function.

If *contourNameStr* contains a wave name, *instance* identifies which contour plot of *contourNameStr* you want information about. *instance* is usually 0 because there is normally only one instance of a wave displayed as a contour plot in a graph. Set *instance* to 1 for information about the second contour plot of *contourNameStr*, etc. If *contourNameStr* is "", then information is returned on the *instance*th contour plot in the graph.

If *contourNameStr* contains an instance name, and *instance* is zero, the instance is taken from *contourNameStr*. If *instance* is greater than zero, the wave name is extracted from *contourNameStr*, and information is returned concerning the *instance*th instance of the wave.

x and *y* specify the X and Y coordinates of the value to be returned. This may or may not be the location of a data point in the wave selected by *contourNameStr* and *instance*.

Set *pointFindingTolerance* =1e-5 to overcome the effects of perturbation (see the perturbation keyword of the **ModifyContour** operation).

The default value is 1e-15 to account for rounding errors created by the triangulation scaling (see ModifyContour's equalVoronoiDistances keyword), which works well ModifyContour perturbation=0.

A value of 0 would require an exact match between the scaled x/y coordinate and the scaled and possibly perturbed coordinates to return the original z value; that is an unlikely outcome.

Details

For gridded contour data, ContourZ returns NaN if *x* or *y* falls outside the XY domain of the contour data. If *x* and *y* fall on the contour data grid, the corresponding Z value is returned.

For XYZ triplet contour data, ContourZ returns the null value if *x* or *y* falls outside the XY domain of the contour data. You can set the null value to *v* with this command:

```
ModifyContour contourName nullValue=v
```

If *x* and *y* match one of the XYZ triplet values, the corresponding Z value from the triplet usually won't be returned because Igor uses the Watson contouring algorithm which perturbs the x and y values by a small random amount. This also means that normally x and y coordinates on the boundary will return a null value about half the time if perturbation is on and *pointFindingTolerance* is greater than 1e-5.

Examples

Because ContourZ can interpolate the Z value of the contour data at any X and Y coordinates, you can use ContourZ to convert XYZ triplet data into gridded data:

```
// Make example XYZ triplet contour data
Make/O/N=50 wx,wy,wz
wx= enoise(2)           // x = -2 to 2
wy= enoise(2)           // y = -2 to 2
wz= exp(-(wx[p]*wx[p] + wy[p]*wy[p]))      // XY gaussian, z= 0 to 1
```

```
// ContourZ requires a displayed contour data set
Display; AppendXYZContour wz vs {wx,wy};DelayUpdate
ModifyContour wz autolevels={*,*,0}         // no contour levels are needed
ModifyContour wz xymarkers=1                // show the X and Y locations

// Set the null (out-of-XY domain) value
ModifyContour wz nullValue=NaN              // default is min(wz) - 1

// Convert to grid: Make matrix that spans X and Y
Make/O/N=(30,30) matrix
SetScale/I x, -2, 2, "", matrix
SetScale/I y, -2, 2, "", matrix
matrix= ContourZ("","wz",0,x,y)             // or = ContourZ("","",0,x,y)
AppendImage matrix
```

Watson, David F., *Contouring: A Guide To The Analysis and Display of Spatial Data*, Pergamon, 1992.

ControlBar

ControlBar [***flags***] ***barHeight***

The ControlBar operation sets the height and location of the control bar in a graph.

Parameters

barHeight is in pixels. Setting *barHeight* to zero removes the control bar.

Flags

/L/R/B/T	Designates whether to use the Left, Right, Bottom, or Top (default) window edge, respectively, for the control bar location.
/W=*graphName*	Specifies the name of a particular graph containing a control bar.

Details

The control bar is an area at the top of graphs reserved for controls such as buttons, checkboxes and pop-up menus. A line is drawn between this area and the graph area. The control bar may be assigned a separate background color by pressing Control (*Macintosh*) or Ctrl (*Windows*) and clicking in the area, by right-clicking it (*Windows*), or with the **ModifyGraph** operation. You can not use draw tools in this area.

For graphs with no controls you do not need to use this operation.

Examples

```
Display myData
ControlBar 35       // 35 pixels high

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

ControlInfo

ControlInfo [**/W=*winName***] ***controlName***

The ControlInfo operation returns information about the state or status of the named control in a graph or control panel window or subwindow.

Flags

/G [=*doGlobal*]	If *doGlobal* is non-zero or absent, the position returned via V_top and V_left is in global screen coordinates rather relative to the window containing the control.
/W=*winName*	Looks for the control in the named graph or panel window or subwindow. If /W is omitted, ControlInfo looks in the top graph or panel window or subwindow. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Parameters

controlName is the name of the control in *winName* or in the top graph or panel window. *controlName* may also be the keyword kwBackgroundColor to set V_Red, V_Green, and V_Blue, the keyword kwControlBar to set V_Height, or the keyword kwSelectedControl to set S_value and V_flag.

Details

Information for all controls is returned via the following string and numeric variables:

S_recreation Commands to recreate the named control.

V_disable Disable state of control:

- 0: Normal (enabled, visible).
- 1: Hidden.
- 2: Disabled, visible.

V_Height, V_Width, V_top, V_left
Dimensions and position of the named control in pixels.

The kind of control is returned in V_flag as a positive or negative integer. A negative value indicates the control is incomplete or not active. If V_flag is zero, then the named control does not exist. Information returned for specific control types is as follows:

Button
- V_flag: 1
- V_value: Tick count of last mouse up.
- S_UserData: Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
- S_recreation, V_disable, V_Height, V_Width, V_top, V_left: See descriptions of these at the beginning of this section.

Chart
- V_flag: 6 or -6
- V_value: Current point number.
- S_value: Keyword-packed information string. See **S_value for Chart Details** for more keyword information.
- S_recreation, V_disable, V_Height, V_Width, V_top, V_left: See descriptions of these at the beginning of this section.

CheckBox
- V_flag: 2
- V_value: 0 if it is deselected or 1 if it is selected.
- S_UserData: Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
- S_recreation, V_disable, V_Height, V_Width, V_top, V_left: See descriptions of these at the beginning of this section.

CustomControl
- V_flag: 12
- V_value: Tick count of last mouse up.
- S_UserData: Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
- S_value: Name of the picture used to define the control appearance.
- S_recreation, V_disable, V_Height, V_Width, V_top, V_left: See descriptions of these at the beginning of this section.

GroupBox
- V_flag: 9
- S_value: Title text.
- S_recreation, V_disable, V_Height, V_Width, V_top, V_left: See descriptions of these at the beginning of this section.

ListBox
- V_flag: 11
- V_value: Currently selected row (valid for mode 1 or 2 or modes 5 and 6 when no selWave is used). If no list row is selected, then it is set to -1.

	V_selCol	Currently selected column (valid for modes 5 and 6 when no selWave is used).
	V_horizScroll	Number of pixels the list has been scrolled horizontally to the right.
	V_vertScroll	Number of pixels the list has been scrolled vertically downwards.
	V_rowHeight	Height of a row in pixels.
	V_startRow	The current top visible row.
	S_columnWidths	A comma-separated list of column widths in pixels.
	S_dataFolder	Full path to listWave (if any).
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
	S_value	Name of listWave (if any).
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
PopupMenu	V_flag	3 or -3
	V_Red, V_Green, V_Blue	For color array pop-up menus, these are the encoded color values.
	V_value	Current item number (counting from one).
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
	S_value	Text of the current item. If PopupMenu is a color array then it contains color values encoded as (*r*,*g*,*b*) where *r*, *g*, and *b* are integers from 0 to 65535.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
SetVariable	V_flag	5 or -5
	V_value	Value of the variable. If the SetVariable is used with a string variable, then it is the interpretation of the string as a number, which will be NaN if conversion fails.
	S_dataFolder	Full path to the variable.
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
	S_value	Name of the variable or, if the value was set using _STR: syntax, the string value itself.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
Slider	V_flag	7
	V_value	Numeric value of the variable.
	S_dataFolder	Full path to the variable.
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
	S_value	Name of the variable.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
TabControl	V_flag	8
	V_value	Number of the current tab.
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the **GetUserData** operation.
	S_value	Tab text.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.

TitleBox
V_flag 10
S_dataFolder Full path if text is from a string variable.
S_value Name if text is from a string variable.
S_recreation, V_disable, V_Height, V_Width, V_top, V_left
See descriptions of these at the beginning of this section.

ValDisplay
V_flag 4 or -4
V_value Displayed value.
S_value Text of expression that ValDisplay evaluates.
S_recreation, V_disable, V_Height, V_Width, V_top, V_left
See descriptions of these at the beginning of this section.

kwBackgroundColor
V_Red, V_Green, V_Blue
If *controlName* is kwBackgroundColor then this is the color of the control panel background. This color is usually the default user interface background color, as set by the Appearance control panel on the Macintosh or by the Appearance tab of the Display Properties on Windows, until changed by `ModifyPanel cbRGB`.

kwControlBar
V_Height If *controlName* is kwControlBar then this is the height (in pixels) of the control bar area in a graph or of an entire panel.

kwSelectedControl
V_flag If *controlName* is kwSelectedControl then V_flag is 1 if a control is selected or 0 if not. (**SetVariable** and **ListBox** controls can be selected, most other controls cannot.)
S_value Name of selected control (if any) or `""`.

S_value for Chart Details

The following applies *only* to the keyword-packed information string returned in S_value for a chart. S_value will consist of a sequence of sections with the format: "*keyword***:***value***;**" You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions. Here are the S_value keywords:

Keyword	Type	Meaning
FNAME	string	Name of the FIFO chart is monitoring.
LHSAMP	number	Left hand sample number.
NCHANS	number	Number of channels displayed in chart.
PPSTRIP	number	The chart's points per strip value.
RHSAMP	number	Right hand sample number (same as V_value).

In addition, ControlInfo writes fields to S_value for each channel in the chart. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named "Pressure" then the following would appear in the S_value string: "CHNAME4:Pressure". In the following table, the channel's number is represented by #:

Keyword	Type	Meaning
CHCTAB#	number	Channel's color table value as set by Chart ctab keyword.
CHGAIN#	number	Channel's gain value as set by Chart gain keyword.
CHNAME#	string	Name of channel defined by FIFO.
CHOFFSET#	number	Channel's offset value as set by Chart offset keyword.

Examples

```
ControlInfo myChart; Print S_value
```

Prints the following to the history area:

```
FNAME:myFIFO;NCHANS:1;PPSTRIP:1100;RHSAMP:271;LHSAMP:-126229;
```

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

ControlNameList

ControlNameList(*winNameStr* [, *listSepStr* [, *matchStr*]])

The ControlNameList function returns a string containing a list of control names in the graph or panel window or subwindow identified by *winNameStr*.

Parameters

winNameStr can be "" to refer to the top graph or panel window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

The optional parameter *listSepStr* should contain a single character such as "," or ";" to separate the names; the default value is ";".

The optional parameter *matchStr* is some combination of normal characters and the asterisk wildcard character that matches anything. To use *matchStr*, *listSepStr* must also be used. See **stringmatch** for wildcard details.

Only control names that satisfy the match expression are returned. For example, "*_tab0" matches all control names that end with "_tab0". The default is "*", which matches all control names.

Examples

```
NewPanel
Button myButton
Checkbox myCheck
Print ControlNameList("")                   // prints "myButton;myCheck;"
Print ControlNameList("", ";", "*Check")    // prints "myCheck;"
```

ControlUpdate

ControlUpdate [**/A/W=*winName***][***controlName***]

The ControlUpdate operation updates the named control or all controls in a window, which can be the top graph or control panel or the named graph or control panel if you use /W.

Flags

/A	Updates all controls in the window. You must omit *controlName*.
/W=*winName*	Specifies the window or subwindow containing the control. If you omit *winName* it will use the top graph or control panel window or subwindow. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

ControlUpdate is useful for forcing a pop-up menu to rebuild, to update a ValDisplay control, or to forcibly accept a SetVariable's currently-being-edited value.

Normally, a pop-up menu rebuilds only when the user clicks on it. If you set up a pop-up menu so that its contents depend on a global string variable, on a user-defined string function or on an Igor function (e.g., **WaveList**), you may want to force the pop-up menu to be updated at your command.

Usually, a ValDisplay control displays the value of a global variable or of an expression involving a global variable. If the global variable changes, the ValDisplay will automatically update. However, you can create a ValDisplay that displays a value that does not depend on a global variable. For example, it might display

the result of an external function. In a case like this, the ValDisplay will not automatically update. You can update it by calling ControlUpdate.

When a SetVariable control is being edited, the text the user types isn't "accepted" (or processed) until the user presses Return or Enter. ControlUpdate effectively causes the named control to act as though the user has pressed one of those keys. If /A is specified, the currently active SetVariable control (if any) is affected this way. The motivation here is that the user may have typed a new value without having yet pressed return, and then may click a button in a different panel which runs a routine that uses the SetVariable value as input. The user expected the typed value to have been accepted but the variable has not yet been set. Calling ControlUpdate/A on the first panel will read the typed value in the variable, avoiding a discrepancy between the visible value of the SetVariable control and the actual value of the variable.

Examples

```
NewPanel;DoWindow/C PanelX
String/G popupList="First;Second;Third"
PopupMenu oneOfThree value=popupList        // popup shows "First"
popupList="1;2;3"                           // popup is unchanged
ControlUpdate/W=PanelX oneOfThree           // popup shows "1"
```

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **ValDisplay** and **WaveList** operations.

ConvexHull

convexHull [***flags***]***xwave, ywave***

convexHull [***flags***] ***tripletWave***

The ConvexHull operation calculates the convex hull in either 2 or 3 dimensions. The dimensionality is deduced from the input wave(s). If the input consists of two 1D waves of the same length, the number of dimensions is assumed to be 2. If the input consists of a single triplet wave (a wave of 3 columns), then the number of dimensions is 3.

In 2D cases the operation calculates the convex hull and produces the result in a pair of x and y waves, W_XHull and W_YHull.

In 3D cases the operation calculates the convex hull and stores it in a triplet wave M_Hull that describes ordered facets of the convex hull.

ConvexHull returns an error if the input waves have fewer than 3 data points.

Flags

/C	(2D convex hull only) adds the first point to the end of the W_XHull and W_YHull waves so that the first and the last points are the same.
/E	(3D case only) if you use this flag the operation also creates a wave that lists the indices of the vertices which are not part of the convex hull, i.e., vertices which are interior to the hull. The output is in the wave W_HullExcluded.
/I	(3D convex hull only) use this flag to get the corresponding index of the vertex as the fourth column in the M_Hull wave.
/S	(3D convex hull only) use this flag if you want the resulting M_Hull to have NaN lines separating each triangle.
/T=*tolerance*	(3D case only) default tolerance for measuring if a point is inside or outside the convex hull is 1.0×10^{-20}. You can use any other positive value.
/V	(3D case only) if you use this flag the operation also creates a wave containing the output in a list of vertex indices. The wave M_HullVertices contains a row per triangle where each entry on a row corresponds to the index of the input vertex.
/Z	No error reporting.

Examples

```
Make/O/N=33 xxx=gnoise(5),yyy=gnoise(7)
Convexhull/c xxx,yyy
Display W_Yhull vs W_Xhull
Appendtograph yyy vs xxx
ModifyGraph mode(yyy)=3,marker(yyy)=8,rgb(W_YHull)=(0,15872,65280)
```

Convolve

Convolve [**/A/C**] ***srcWaveName, destWaveName*** [**, *destWaveName***]…

The Convolve operation convolves *srcWaveName* with each destination wave, putting the result of each convolution in the corresponding destination wave.

Convolve is not multidimensional aware. Some multidimensional convolutions are covered by the **MatrixConvolve**, **MatrixFilter**, and **MatrixOp** operations

Flags

/A	Acausal linear convolution.
/C	Circular convolution.

Details

Convolve performs linear convolution unless the /C or /A flag is used. See the diagrams in the examples below.

Depending on the type of convolution, the destination waves' lengths may increase. *srcWaveName* is not altered unless it also appears as a destination wave.

If *srcWaveName* is real-valued, each destination wave must be real-valued, and if *srcWaveName* is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; calculations are performed in the higher precision.

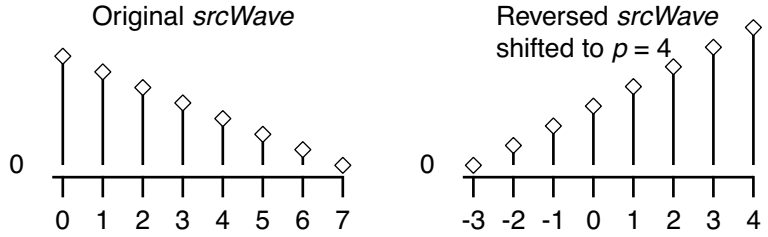
The linear convolution equation is:

$$destWaveOut[p] = \sum_{m=0}^{N-1} destWaveIn[m] \cdot srcWave[p-m]$$

where *N* is the number of points in the longer of *destWaveIn* and *srcWave*. For circular convolution, the index [*p -m*] is wrapped around when it exceeds the range of [0,numpnts(*srcWave*)-1]. For acausal convolution, when [*p -m*] exceeds the range a zero value is substituted for *srcWave* [*p -m*]. Similar operations are applied to *destWaveIn* [*m*].

Another way of looking at this equation is that, for all *p*, *destWaveOut*[*p*] equals the sum of the point-by-point products from 0 to *p* of the destination wave and an end-to-end reversed copy of the source wave that has been shifted to the right by *p*.

The following diagram shows the reversed/shifted *srcWave* that would be combined with *destWaveIn*. The points numbered 0 through 4 of the reversed *srcWave* would be multiplied with *destWaveIn*[0…4] and summed to produce *destWaveOut*[4]:



For linear and acausal convolution, the destination wave is first zero-padded by one less than the length of the source wave. This prevents the "wrap-around" effect that occurs in circular convolution. The zero-padded points are removed after acausal convolution, and retained after linear convolution. The X scaling of the waves is ignored.

The convolutions are performed by transforming the source and destination waves with the Fast Fourier Transform, multiplying them in the frequency domain, and then inverse-transforming them into the destination wave(s).

The convolution is performed in segments if the resulting wave has more than 256 points and the destination wave has twice as many points as the source wave. For acausal convolution, the length of the resulting wave is considered to be (numpnts(*srcWaveName*) +numpnts(*destWaveName*)-1) for this calculation.

Applications

The usual application of convolution is to compute the response of a linear system defined by its impulse response to an input signal. *srcWaveName* would contain the impulse response, and the destination wave would initially contain the input signal. After the Convolve operation has completed, the destination wave contains the output signal.

Use linear convolution when the source wave contains an impulse response (or filter coefficients) where the first point of *srcWave* corresponds to no delay ($t = 0$).

Use circular convolution for the case where the data in *srcWaveName* and *destWaveName* are considered to endlessly repeat (or "wrap around" from the end back to the start), which means no zero padding is needed.

Use acausal convolution when the source wave contains an impulse response where the middle point of *srcWave* corresponds to no delay ($t = 0$).

See Also

Convolution on page III-249 for illustrated examples. **MatrixOp**.

References

A very complete explanation of circular and linear convolution can be found in sections 2.23 and 2.24 of Rabiner and Gold, *Theory and Application of Digital Signal Processing*, Prentice Hall, 1975.

CopyFile

CopyFile [***flags***][***srcFileStr***] [**as** ***destFileOrFolderStr***]

The CopyFile operation copies a file on disk.

Parameters

srcFileStr can be a full path to the file to be copied (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the source file from *srcFileStr* and *pathName*, it displays a dialog allowing you to specify the source file.

destFileOrFolderStr is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with pathName.

If /D is specified, the source file is copied inside the folder using the source file's name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-398 for details on forming the path.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

Flags

/D — Interprets *destFileOrFolderStr* as the name of (or path to) an existing folder (or "directory"). Without /D, *destFileOrFolderStr* is interpreted as the name of (or path to) a file.

If *destFileOrFolderStr* is not a full path to a folder, it is relative to the folder associated with pathName.

/I [=*i*] — Specifies the level of user interactivity.

- /I=0: Interactive only if one or *srcFileStr* or *destFileOrFolderStr* is not specified or if the source file is missing. (Same as if /I was not specified.)
- /I=1: Interactive even if *srcFileStr* is specified and the source file exists.
- /I=2: Interactive even if *destFileOrFolderStr* is specified.
- /I=3: Interactive even if *srcFileStr* is specified, the source file exists, and *destFileOrFolderStr* is specified. Same as /I only.

/M=*messageStr*	Specifies the prompt message in the Open File dialog. If /S is not used, then *messageStr* will be used for both Open File and for Save File dialogs.
/O	Overwrites any existing destination file.
/P=*pathName*	Specifies the folder to look in for the source file, and the folder into which the file is copied. *pathName* is the name of an existing symbolic path. Using /P means that both *srcFileStr* and *destFileOrFolderStr* must be either simple file or folder names, or paths relative to the folder specified by *pathName*.
/S=*saveMessageStr*	Specifies the prompt message in the Save File dialog.
/Z [=*z*]	Prevents procedure execution from aborting if it attempts to copy a file that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution. /Z=0: Same as no /Z. /Z=1: Copies a file only if it exists. /Z alone has the same effect as /Z=1. /Z=2: Copies a file if it exists or displays a dialog if it does not exist.

Variables

The CopyFile operation returns information in the following variables:

`V_flag`	Set to zero if the file was copied, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
`S_fileName`	Stores the full path to the file that was copied. If an error occurred or if the user cancelled, it is set to an empty string.
`S_path`	Stores the full path to the file copy. If an error occurred or if the user cancelled, it is set to an empty string.

Examples

Copy a file within the same folder using a new name:

```
CopyFile/P=myPath "afile.txt" as "destFile.txt"
```

Copy a file into subfolder using the original name (using /P):

```
CopyFile/D/P=myPath "afile.txt" as ":subfolder"
Print S_Path     // prints "Macintosh HD:folder:subfolder:afile.txt"
```

Copy file into subfolder using the original name (using full paths):

```
CopyFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"
```

Copy a file from one folder to another, assigning the copy a new name:

```
CopyFile "Macintosh HD:folder:afile.txt" as "Server:archive:destFile.txt"
```

Copy user-selected file in any folder as destFile.txt in myPath folder (prompt to save even if destFile.txt doesn't exist):

```
CopyFile/I=2/P=myPath as "destFile.txt"
```

Copy user-selected file in any folder as destFile.txt in any folder:

```
CopyFile as "destFile.txt"
```

CopyFolder

`CopyFolder` `[`***`flags`***`]`[***`srcFolderStr`***`]` `[`**`as`** ***`destFolderStr`***`]`

The CopyFolder operation copies a folder (and its contents) on disk.

Warning: *The CopyFolder command can destroy data* by overwriting another folder and contents!

When overwriting an existing folder on disk, CopyFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category. For further details see **Misc Settings** on page III-414.

If permission is denied, the folder will not be copied and V_Flag will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the /Z flag is specified.

Parameters

srcFolderStr can be a full path to the folder to be copied (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a folder inside the folder associated with *pathName*.

If Igor can not determine the location of the folder from *srcFolderStr* and *pathName*, it displays a dialog allowing you to specify the source folder.

If /P=*pathName* is given, but *srcFolderStr* is not, then the folder associated with *pathName* is copied.

destFolderStr can be a full path to the output (destination) folder (in which case /P is not needed), or a partial path relative to the folder associated with *pathName*.

An error is returned if the destination folder would be inside the source folder.

If Igor can not determine the location of the destination folder from *destFolderStr* and *pathName*, it displays a dialog allowing you to specify or create the destination folder.

If you use a full or partial path for either folder, see **Path Separators** on page III-398 for details on forming the path.

Flags

/D — Interprets *destFolderStr* as the name of (or path to) an existing folder (or directory) to copy the source folder into. Without /D, *destFolderStr* is interpreted as the name of (or path to) the copied folder.

If *destFolderStr* is not a full path to a folder, it is relative to the folder associated with *pathName*.

/I [=*i*] — Specifies the level of user interactivity.

- /I=0: Interactive only if the source or destination folder is not specified or if the source folder is missing. (Same as if /I was not specified.)
- /I=1: Interactive even if the source folder is specified and it exists.
- /I=2: Interactive even if *destFolderStr* is specified.
- /I=3: Interactive even if the source folder is specified, the source file exists, and *destFolderStr* is specified. Same as /I only.

/M=*messageStr* — Specifies the prompt message in the Select (source) Folder dialog. If /S is not used, then *messageStr* will be used for the Select Folder dialog and for the Create Folder dialog.

/O — Overwrite existing destination folder, if any.

On Macintosh, a Macintosh-style overwrite-move is performed in which the source folder completely replaces the destination folder.

On Windows, a Windows-style mix-in move is performed in which the contents of the source folder are moved into the destination folder, replacing any same-named files but leaving other files in place.

/P=*pathName* — Specifies the folder to look in for the source folder. *pathName* is the name of an existing symbolic path.

If *srcFolderStr* is not specified, the folder associated with *pathName* is copied.

Using /P means that *srcFolderStr* (if specified) and *destFolderStr* must be either simple folder names or paths relative to the folder specified by *pathName*.

/S=*saveMessageStr* — Specifies the prompt message in the Create Folder dialog.

/Z [=*z*] — Prevents procedure execution from aborting if it attempts to copy a file that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution.

- /Z=0: Same as no /Z.
- /Z=1: Copies a folder only if it exists. /Z alone has the same effect as /Z=1.
- /Z=2: Copies a folder if it exists or displays a dialog if it does not exist.

Variables

The CopyFolder operation returns information in the following variables:

V_flag	Set to zero if the folder was copied, to -1 if the user cancelled either the Select Folder or Create Folder dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
S_fileName	Stores the full path to the folder that was copied, with a trailing semicolon. If an error occurred or if the user cancelled, it is set to an empty string.
S_path	Stores the full path to the folder copy, with a trailing semicolon. If an error occurred or if the user cancelled, it is set to an empty string.

Details

You can use only /P=*pathName* (without *srcFolderStr*) to specify the source folder to be copied.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

Examples

Copy the folder that the current experiment is stored in:

```
CopyFile/P=home as "HD:Copy Of Folder Experiment Is In"
```

Copy the Igor Extensions Folder to the Windows desktop:

```
CopyFile/D/P=Igor ":Igor Extensions" as "C:WINDOWS:Desktop"
```

Ask the user to select a folder, starting with the Igor folder, and then make a copy of that folder in the Igor Pro folder:

```
CopyFile/I=2/P=Igor as "::Folder Copy"
```

Copy an entire disk inside a folder:

```
CopyFolder/O/D "Floppy" as "HD:Desktop Folder:Copy Into Here"
```

Open, **MoveFile**, **DeleteFile**, **MoveFolder**, **NewPath**, and **IndexedDir** operations, and **Symbolic Paths** on page II-34.

CopyScales

CopyScales [**/I/P**] ***srcWaveName, waveName*** [**, *waveName***]…

The CopyScales operation copies the x, y, z, and t scaling, x, y, z, and t units, the data Full Scale and data units from *srcWaveName* to the other waves.

Flags

/I	Copies the x, y, z, and t scaling in inclusive format.
/P	Copies the x, y, z, and t scaling in slope/intercept format (x0, dx format).

Details

Normally the x, y, z, and t (dimension) scaling is copied in min/max format. However, if you use /P, the dimension scaling is copied in slope/intercept format so that if *srcWaveName* and the other waves have differing dimension size (number of points if the wave is a 1D wave), then their dimension values will still match for the points they have in common. Similarly, /I uses the inclusive variant of the min/max format. See **SetScale** for a discussion of these dimension scaling formats.

If a wave has only one point, /I mode reverts to /P mode.

CopyScales copies scales only for those dimensions that *srcWaveName* and *waveName* have in common.

See Also

x, **y**, **z**, and **t** scaling functions.

Correlate

Correlate [**/AUTO/C/NODC**] ***srcWaveName, destWaveName*** [**, *destWaveName***]…

The Correlate operation correlates *srcWaveName* with each destination wave, putting the result of each correlation in the corresponding destination wave.

Flags

/AUTO	Auto-correlation scaling. This forces the X scaling of the destination wave's center point to be x=0, and divides the destination wave by the center point's value so that the center value is exactly 1.0.

If srcWaveName and destWaveName do not have the same number of points, this flag is ignored.

/AUTO is not compatible with /C.

/C Circular correlation. (See **Compatibility Note**.)

/NODC Removes the mean from the source and destination waves before computing the correlations. Removing the mean results in the un-normalized auto- or cross-covariance.

"DC" is an abbrevation of "direct current", an electronics term for the non-varying average value component of a signal.

Details

Note: To compute a single-value correlation number use the **StatsCorrelation** function which returns the Pearson's correlation coefficient of two same-length waves.

Correlate performs linear correlation unless the /C flag is used.

Depending on the type of correlation, the length of the destination may increase. *srcWaveName* is not altered unless it also appears as a destination wave.

If the source wave is real-valued, each destination wave must be real-valued and if the source wave is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; calculations are performed in the higher precision.

The linear correlation equation is:

$$destWaveOut[p] = \sum_{m=0}^{N-1} srcWave[m] \cdot destWaveIn[p+m]$$

where N is the number of points in the longer of *destWaveIn* and *srcWave*.

For circular correlation, the index [$p+m$] is wrapped around when it exceeds the range of `[0,numpnts(destWaveIn)-1]`. For linear correlation, when [$p+m$] exceeds the range a zero value is substituted for *destWaveIn*[$p+m$]. When m exceeds `numpnts(srcWave)-1`, 0 is used instead of *srcWave*[m].

Comparing this with the **Convolve** operation, which is the linear convolution:

$$destWaveOut[p] = \sum_{m=0}^{N-1} destWaveIn[m] \cdot srcWave[p-m]$$

you can see that the only difference is that for correlation the source wave is *not* reversed before shifting and combining with the destination wave.

The Correlate operation is not multidimensional aware. For details, see **Analysis on Multidimensional Waves** on page II-110 and in particular **Analysis on Multidimensional Waves** on page II-110.

Compatibility Note

Prior to Igor Pro 5, Correlate/C scaled and rotated the results improperly (the result was often rotated left by one and the X scaling was entirely negative).

Now the destination wave's X scaling is unaltered and it does not rotate the result. You can force the old behavior for compatibility with old procedures that depend on the old behavior by setting `root:V_oldCorrelationScaling=1`.

A better way to get identical Correlate/C results with all versions of Igor Pro is to use this code, which rotates the result so that x=0 is always the first point in *destWave*, no matter which Igor Pro version runs this code (currently, it doesn't change anything and runs extremely quickly because it does no rotation):

```
Correlate/C srcWave, destWave
Variable pointAtXEqualZero= x2pnt(destWave,0)     // 0 for Igor Pro 5
Rotate -pointAtXEqualZero,destWave
SetScale/P x, 0, DimDelta(destWave,0), "", destWave
```

Applications

A common application of correlation is to measure the similarity of two input signals as they are shifted by one another.

Often it is desirable to normalize the correlation result to 1.0 at the maximum value where the two inputs are most similar. To normalize *destWaveOut*, compute the RMS values of the input waves and the number of points in each wave:

```
WaveStats/Q srcWave
Variable srcRMS = V_rms
Variable srcLen = numpnts(srcWave)

WaveStats/Q destWave
Variable destRMS = V_rms
Variable destLen = numpnts(destWave)

Correlate srcWave, destWave                // overwrites destWave

// now normalize to max of 1.0
destWave /= (srcRMS * sqrt(srcLen) * destRMS * sqrt(destLen))
```

Another common application is using autocorrelation (where *srcWaveName* and *destWaveName* are the same) to determine Power Spectral Density. In this case it better to use the **DSPPeriodogram** operation which provides more options.

See Also

Convolution on page III-249 and **Correlation** on page III-251 for illustrated examples. See the **Convolve** operation for algorithm implementation details, which are identical except for the lack of source wave reversal, and the lack of the /A (acausal) flag.

The **MatrixOp**, **StatsCorrelation**, **StatsCircularCorrelationTest**, **StatsLinearCorrelationTest**, and **DSPPeriodogram** operations.

References

An explanation of autocorrelation and Power Spectral Density (PSD) can be found in Chapter 12 of Press, William H., *et al*., *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

WaveMetrics provides Igor Technical Note 006, "DSP Support Macros" that computes the PSD with options such as windowing and segmenting. See the Technical Notes folder. Some of the techniques discussed there are available as Igor procedure files in the "WaveMetrics Procedures:Analysis:" folder.

Wikipedia: http://en.wikipedia.org/wiki/Correlation

Wikipedia: http://en.wikipedia.org/wiki/Cross_covariance

Wikipedia: http://en.wikipedia.org/wiki/Autocorrelation_function

cos

cos(*angle*)

The cos function returns the cosine of *angle* which is in radians.

In complex expressions, *angle* is complex, and `cos(`*angle*`)` returns a complex value:

$$\cos(x+iy) = \cos(x)\cosh(y) - i\sin(x)\sinh(y).$$

See Also

sin, **tan**, **sec**, **csc**, **cot**

cosh

cosh(*num*)

The cosh function returns the hyperbolic cosine of *num*:

$$\cosh(x) = \frac{e^x + e^{-x}}{2}.$$

In complex expressions, *num* is complex, and `cosh(`*num*`)` returns a complex value.

See Also

sinh, **tanh**, **coth**

cot

cot(*angle*)

The cot function returns the cotangent of *angle* which is in radians.

In complex expressions, *angle* is complex, and cot(*angle*) returns a complex value.

See Also

sin, **cos**, **tan**, **sec**, **csc**

coth

coth(*num*)

The coth function returns the hyperbolic cotangent of *num*:

$$\coth(x) = \frac{e^x + e^{-x}}{e^x - e^{-x}}.$$

In complex expressions, *num* is complex, and coth(*num*) returns a complex value.

See Also

sinh, **cosh**, **tanh**

CountObjects

CountObjects(*sourceFolderStr, objectType*)

The CountObjects function returns the number of objects of the specified type in the data folder specified by the string expression.

For Igor Pro 6.1 or later, **CountObjectsDFR** is preferred.

Parameters

sourceFolderStr can be either ":" or "" to specify the current data folder. You can also use a full or partial data folder path. *objectType* should be one of the following values:

objectType	**What CountObjects Counts**
1	Waves
2	Numeric variables
3	String variables
4	Data folders

See Also

Chapter II-8, **Data Folders**, and the **GetIndexedObjName** function.

CountObjectsDFR

CountObjectsDFR(*dfr,objectType*)

The CountObjectsDFR function returns the number of objects of the specified type in the data folder specified by the data folder reference *dfr*.

Requires Igor Pro 6.1 or later.

CountObjectsDFR is the same as CountObjects except the first parameter, *dfr*, is a data folder reference instead of a string containing a path.

Parameters

objectType is one of the following values:

objectType	What CountObjectsDFR Counts
1	Waves
2	Numeric variables
3	String variables
4	Data folders

See Also

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-61.

GetIndexedObjNameDFR

cpowi

cpowi(*num, ipow*)

This function is obsolete as the exponentiation operator ^ handles complex expressions with any combination of real, integer and complex arguments. See **Operators** on page IV-5. The cpowi function returns a complex number resulting from raising complex *num* to integer-valued power *ipow*. *ipow* can be positive or negative, but if it is not an integer cpowi returns (NaN, NaN).

CreateAliasShortcut

CreateAliasShortcut [*flags*][*targetFileDirStr*] [as *aliasFileStr*]

The CreateAliasShortcut operation creates an alias (*Macintosh*) or shortcut (*Windows*) file on disk. The alias can point to either a file or a folder. The file or folder pointed to is called the "target" of the alias or shortcut.

Parameters

targetFileDirStr can be a full path to the file or folder to make an alias or shortcut for, a partial path relative to the folder associated with /P=*pathName*, or the name of a file or folder in the folder associated with *pathName*.

If Igor can not determine the location of the file or folder from *targetFileDirStr* and *pathName*, it displays a dialog allowing you to specify a target file. Use /D to select a folder as the alias target, instead.

aliasFileStr can be a full path to the created alias file, a partial path relative to the folder associated with *pathName* if specified, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the alias or shortcut file from *aliasFileStr* and *pathName*, it displays a File Save dialog allowing you to create the file.

If you use a full or partial path for either *targetFileDirStr* or *aliasFileStr*, see **Path Separators** on page III-398 for details on forming the path.

Folder paths should not end with single path separators. See the **MoveFolder Details** section.

Flags

/D — Uses the Select Folder dialog rather than Open File dialog when *targetFileDirStr* is not fully specified.

/I [=*i*] — Specifies the level of user interactivity.

- *i*=0: Interactive only if one or *targetFileDirStr* or *aliasFileStr* is not specified or if the target file is missing. (Same as if /I was not specified.)
- *i*=1: Interactive even if *targetFileDirStr* is fully specified and the target file exists.
- *i*=2: Interactive even if *targetFileDirStr* is specified.
- *i*=3: Interactive even if *targetFileDirStr* is specified and the target file exists. Same as /I only.

/M=*messageStr* — Specifies the prompt message in the Open File or Select Folder dialog. If /S is not specified, then *messageStr* will be used for Open File (or Select Folder) and for Save File dialogs.

/O — Overwrites any existing file with the alias or shortcut file.

/P=*pathName* — Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.

/S=*saveMessageStr* Specifies the prompt message in the Save File dialog when creating the alias or shortcut file.

/Z[=*z*] Prevents procedure execution from aborting if the procedure tries to copy a file that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution.

- /Z=0: Same as no /Z.
- /Z=1: Creates an alias to a file or folder only if it exists. /Z alone has the same effect as /Z=1.
- /Z=2: Creates an alias to a file or folder only if it exists and displaying a dialog if it does not exist.

Variables

The CreateAliasShortcut operation returns information in the following variables:

`V_flag`
- 0: Created an alias or shortcut file.
- -1: User cancelled any of the Open File, Select Folder, or Save File dialogs.
- Other: An error occurred, such as the target file does not exist.

`S_path` Full path to the target file or folder. If an error occurred or if the user cancelled, it is an empty string.

`S_fileName` Full path to the created alias or shortcut file. If an error occurred or if the user cancelled, it is an empty string.

Examples

Create a shortcut (*Windows*) to the current experiment, on the desktop:

```
String target= Igorinfo(1)+".pxp" // experiments are usually .pxp on Windows
CreateAliasShortcut/O/P=home target as "C:WINDOWS:Desktop:"+target
```

Create an alias (*Macintosh*) to the VDT XOP in the Igor Extensions folder:

```
String target= ":More Extensions:Data Acquisition:VDT"
CreateAliasShortcut/O/P=Igor target as ":Igor Extensions:VDT alias"
```

Create an alias to the "HD 2" disk. Put the alias on the desktop:

```
CreateAliasShortcut/D/O "HD 2" as "HD:Desktop Folder:Alias to HD 2"
```

See Also

Symbolic Paths on page II-34.

The **Open**, **MoveFile**, **DeleteFile**, and **GetFileFolderInfo** operations. The **IgorInfo** and **ParseFilePath** functions.

CreationDate

`CreationDate(`*`waveName`*`)`

Returns creation date of wave as an Igor date/time value, which is the number of seconds from 1/1/1904.

The returned value is valid for waves created with Igor Pro 3.0 or later. For waves created in earlier versions, it returns 0.

See Also

modDate.

Cross

`Cross [/T/Z] `*`vectorA, vectorB`*` [, `*`vectorC`*`]`

The Cross operation computes the cross products *vectorA* x *vectorB* and *vectorA* x (*vectorB* x *vectorC*). Each vector is a 1D real wave containing 3 rows. Stores the result in the wave W_Cross in the current data folder.

Flags

/T Stores output in a row instead of a column in W_Cross.

/Z Generates no errors for any unsuitable inputs.

csc

csc(*angle*)

The csc function returns the cosecant of *angle* which is in radians.

$$\csc(x) = \frac{1}{\sin(x)}.$$

In complex expressions, *angle* is complex, and csc(*angle*) returns a complex value.

See Also

sin, **cos**, **tan**, **sec**, **cot**

CsrInfo

CsrInfo(*cursorName* [, *graphNameStr*])

The CsrInfo function returns a keyword-value pair list of information about the specified cursor (*cursorName* is A through J) in the top graph or graph specified by *graphNameStr*. It returns "" if the cursor is not in the graph.

Details

The returned string contains information about the cursor in the following format:

```
TNAME:traceName; ISFREE:freeNum;POINT:xPointNumber;[YPOINT:yPointNumber;]
RECREATION:command;
```

The *traceName* value is the name of the graph trace or image to which it is attached or which supplies the x (and y) values even if the cursor isn't attached to it.

If TNAME is empty, fields POINT, ISFREE, and YPOINT are not present.

The *freeNum* value is 1 if the cursor is not attached to anything, 0 if attached to a trace or image.

The POINT value is the same value **pcsr** returns.

The YPOINT keyword and value are present only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot or when the cursor is free. It's value is the same as returned by **qcsr**.

If cursor is free, POINT and YPOINT values are fractional relative positions (see description in the **Cursor** command).

The RECREATION keyword contains the Cursor commands (including /W) necessary to regenerate the current settings.

Examples

```
Variable aExists= strlen(CsrInfo(A)) > 0   // A is a name, not a string
Variable bIsFree= NumberByKey("ISFREE",CsrInfo(B,"Graph0"))
```

See Also

The **Cursor** operation and the **hcsr**, **pcsr**, **qcsr**, **vcsr**, **xcsr**, and **zcsr** functions. **Cursors — Moving Cursor Calls Function** on page IV-294.

CsrWave

CsrWave(*cursorName* [, *graphNameStr* [, *wantTraceName*]])

The CsrWave function returns a string containing the name of the wave the specified cursor (A through J) is on in the top (or named) graph. If the optional *wantTraceName* is nonzero, the trace name is returned. A trace name is the wave name with optional instance notation (see **ModifyGraph (traces)**).

Details

The name of a wave by itself is not sufficient to identify the wave because it does not specify what data folder contains the wave. Thus, if you are calling CsrWave for the purpose of passing the wave name to other procedures, you should use the **CsrWaveRef** function instead. Use CsrWave if you want the name of the wave to use in an annotation or a notebook.

Examples

```
String waveCursorAIsOn = CsrWave(A)            // not CsrWave("A")
String waveCursorBIsOn = CsrWave(B,"Graph0")   // in specified graph
String traceCursorBIsOn = CsrWave(B,"",1)      // trace name in top graph
```

CsrWaveRef

CsrWaveRef(*cursorName* [, *graphNameStr*])

The CsrWaveRef function returns a wave reference to the wave the specified cursor (A through J) is on in the top (or named) graph.

Details

The wave reference can be used anywhere Igor is expecting the name of a wave (not a string containing the name of a wave).

CsrWaveRef should be used in place of the CsrWave() string function to work properly with data folders.

Examples

```
Print CsrWaveRef(A)[50]                 // not CsrWaveRef("A")
Print CsrWaveRef(B,"Graph0")[50]        // in specified graph
```

See Also

See **Wave Reference Functions** on page IV-173.

CsrXWave

CsrXWave(*cursorName* [, *graphNameStr*])

The CsrXWave function returns a string containing the name of the wave supplying the X coordinates for an XY plot of the Y wave the specified cursor (A through J) is attached to in the top (or named) graph.

Details

CsrXWave returns an empty string ("") if the wave the cursor is on is not plotted versus another wave providing the X coordinates (that is, if the wave was not plotted with a command such as `Display theWave vs anotherWave`).

The name of a wave by itself is not sufficient to identify the wave because it does not specify what data folder contains the wave. Thus, if you are calling CsrXWave for the purpose of passing the wave name to other Igor procedures, you should use the **CsrXWaveRef** function instead. Use CsrXWave if you want the name of the wave to use in an annotation or a notebook.

Examples

```
Display ywave vs xwave
```

ywave supplies the Y coordinates and xwave supplies the X coordinates for this XY plot.

```
Cursor A ywave,0
Print CsrXWave(A)       // prints xwave
```

CsrXWaveRef

CsrXWaveRef(*cursorName* [, *graphNameStr*])

The CsrXWaveRef function returns a wave reference to the wave supplying the X coordinates for an XY plot of the Y wave the specified cursor (A through J) is attached to in the top (or named) graph.

Details

The wave reference can be used anywhere Igor is expecting the name of a wave (not a string containing the name of a wave).

CsrXWaveRef returns a null reference (see **WaveExists**) if the wave the cursor is on is not plotted versus another wave providing the X coordinates (that is, if the wave was not plotted with a command such as `Display theWave vs anotherWave`). CsrXWaveRef should be used in place of the CsrXWave string function to work properly with data folders.

Examples

```
Display ywave vs xwave
```

ywave supplies the Y coordinates and xwave supplies the X coordinates for this XY plot.

```
Cursor A ywave,0
Print CsrXWaveRef(A)[50]      // prints value of xwave at point #50
```

See Also

See **Wave Reference Functions** on page IV-173.

CTabList

CTabList()

The CTabList string function returns a semicolon-separated list of the names of built-in color tables. This can be useful when creating pop-up menus in control panels.

Color tables available through version 4:

Grays	Rainbow	YellowHot	BlueHot	BlueRedGreen
RedWhiteBlue	PlanetEarth	Terrain		

Additional color tables added for version 5:

Grays256	Rainbow256	YellowHot256	BlueHot256	BlueRedGreen256
RedWhiteBlue256	PlanetEarth256	Terrain256	Grays16	Rainbow16
Red	Green	Blue	Cyan	Magenta
Yellow	Copper	Gold	CyanMagenta	RedWhiteGreen
BlueBlackRed	Geo	Geo32	LandAndSea	LandAndSea8
Relief	Relief19	PastelsMap	PastelsMap20	Bathymetry9
BlackBody	Spectrum	SpectrumBlack	Cycles	Fiddle
Pastels				

Additional color tables added for version 6:

RainbowCycle	Rainbow4Cycles	GreenMagenta16	dBZ14	dBZ21
Web216	BlueGreenOrange	BrownViolet	ColdWarm	Mocha
VioletOrangeYellow	SeaLandAndFire			

Additional color tables added for version 6.2:

Mud	Classification

See Also

See **Color Tables** on page II-349 and **ColorTab2Wave**.

CtrlBackground

CtrlBackground [***key*** [**= *value***]]…

The CtrlBackground operation controls the unnamed background task.

CtrlBackground works only with the unnamed background task. New code should used named background tasks instead. See **Background Tasks** on page IV-279 for details.

Parameters

dialogsOK=1 *or* 0	If 1, your task will be allowed to run while an Igor dialog is present. This can potentially cause crashes unless your task is well-behaved.
noBurst=1 *or* 0	Normally (or noBurst=0), your task will be called at maximum rate if a delay causes normal run times to be missed. Using noBurst=1, will suppress this burst catch up mode.
period=*deltaTicks*	Sets the minimum number of ticks that must pass between invocations of the background task.
start[=*startTicks*]	Starts the background task (designated by SetBackground) when the tick count reaches *startTicks*. If you omit *startTicks* the task starts immediately.
stop	Stops the background task.

See Also

The **BackgroundInfo**, **SetBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and **Background Tasks** on page IV-279.

CtrlNamedBackground

CtrlNamedBackground *taskName*, *keyword* = *value* [, *keyword* = *value* …]

The CtrlNamedBackground operation creates and controls named background tasks.

We recommend that you see **Background Tasks** on page IV-279 for an orientation before working with background tasks.

Important: Unlike the unnamed background task, by default named tasks run when a dialog window is active. This can cause a crash if the background task does things the dialog does not expect. See **Background Tasks and Dialogs** on page IV-281 for details.

Parameters

taskName	*taskName* is the name of the background task or _all_ to control all named background tasks. You can use any valid standard Igor object name as the background task name.
burst [= *b*]	Enable burst catch up mode (off by default, *b*=0). When on (*b*=1), the task is called at the maximum rate if a delay misses normal run times.
dialogsOK [= *d*]	Use dialogsOK=0 to prevent the background task from running when a dialog window is active. By default, dialogsOK=1 is in effect. See **Background Tasks and Dialogs** on page IV-281 for details.
kill [= *k*]	Stops and releases task memory for reuse (*k*=1; default) or continues (*k*=0).
period=*deltaTicks*	Sets the minimum number of ticks (*deltaTicks*) that must pass between background task invocations. *deltaTicks* is truncated to an integer and clipped to a value greater than zero. See **Background Task Period** on page IV-280 for details.
proc=*funcName*	Specifies name of a background user function (see **Details**).
start [=*startTicks*]	Starts when the tick count reaches *startTicks*. A task starts immediately without *startTicks*.
status	Returns background task information in the S_info string variable.
stop [= *s*]	Stops the background task (*s*=1; default) or continues (*s*=0).

Details

The user function you specify via the proc keyword must have the following format:

```
Function myFunc(s)
   STRUCT WMBackgroundStruct &s
   …
```

The members of the `WMBackgroundStruct` are:

Base `WMBackgroundStruct` Structure Members

Member	Description
`char name[MAX_OBJ_NAME+1]`	Background task name.
`uint32 curRunTicks`	Tick count when task was called.
`int32 started`	TRUE when CtrlNamedBackground start is issued. You may clear or set to desired value.
`uint32 nextRunTicks`	Precomputed value for next run but user functions may change this.

You may also specify a user function that takes a user-defined STRUCT as long as the first elements of the structure match the `WMBackgroundStruct` or, preferably, if the first element is an instance of `WMBackgroundStruct`. Use the started field to determine when to initialize the additional fields. Your structure may not include any String, WAVE, NVAR, DFREF or other fields that reference memory that is not part of the structure itself.

If you specify a user-defined structure that matches the first fields rather than containing an instance of `WMBackgroundStruct`, then your function will fail if, in the future, the size of the built-in structure changes. The value of `MAX_OBJ_NAME` is 31 but this may also change.

Your function should return zero unless it wants to stop in which case it should return 1.

You can call CtrlNamedBackground within your background function. You can even switch to a different function if desired.

Use the status keyword to obtain background task information via the S_info variable, which has the format:

`NAME:`*`name`*`;PROC:`*`fname`*`;RUN:`*`r`*`;PERIOD:`*`p`*`;NEXT:`*`n`*`;QUIT:`*`q`*`;FUNCERR:`*`e`*`;`

When parsing S_info, do not rely on the number of key-value pairs or their order. RUN, QUIT, and FUNCERR values are 1 or 0, NEXT is the tick count for the next firing of the task. QUIT is set to 1 when your function returns a nonzero value and FUNCERR is set to 1 if your function could not be used for some reason.

See Also

See **Background Tasks** on page IV-279 for examples.

Also see the Background Task Demo experiment (choose File→Example Experiments→Programming→Background Task Demo).

CtrlFIFO

`CtrlFIFO` ***`FIFOName`*** `[,` ***`key = value`***`]…`

The CtrlFIFO operation controls various aspects of the named FIFO.

Parameters

close	Closes the FIFO's output or review file (if any).
deltaT=*dt*	Documents the data acquisition rate.
doffset=*dataOffset*	Used only with rdfile. Offset to data. If not provided offset is zero.
dsize=*dataSize*	Used only with rdfile. Size of data in bytes. If not provided, then data size is assumed to be the remainder of file. If this assumption is not valid then unexpected results may be observed.
flush	New data in FIFO is flushed to disk immediately.
file=*oRefNum*	File reference number for the FIFO's output file. You obtain this reference number from the **Open** operation used to create the file.
note=*noteStr*	Stores the note string in the file header. It is limited to 255 characters.
rdfile=*rRefNum*	Like rfile but for review of raw data (use Open/R command). Channel data must match raw data in file. Offset from start of file to start of data can be provided using doffset given in same command. If data does not extend all the way to the end of the file, then the number of bytes of data can be provided using dsize in the same command.
rfile=*rRefNum*	File reference number for the FIFO's review file. Use a review file when you are using a FIFO to review existing data. Obtain the reference number from the Open/R operation used to open the file. File may be either unified header/data or a split format where the header contains the name of a file containing the raw data.
size=*s*	Sets number of chunks in the FIFO. The default is 10000. A chunk of data consists of a single data point from each of the FIFO's channels.
start	Starts the FIFO running by setting the time/date in the FIFO header, writing the header to the output file and marking the FIFO active.
stop	Stops the FIFO by flushing data to disk and marking the FIFO as inactive.
swap	Used only with rdfile. Indicates that the raw data file requires byte-swapping when it is read. This would be the case if you are running on a Macintosh, reading a binary file from a PC, or vice versa.

Details

Once start has been issued, the FIFO can accept no further commands except stop.

The FIFO must be in the valid state for you to access its data (using a chart control or using the **FIFO2Wave** operation). When you create a FIFO, using **NewFIFO**, it is initially invalid. It becomes valid when you issue the start command via the CtrlFIFO operation. It remains valid until you change a FIFO parameter using CtrlFIFO.

FIFOs are used for data acquisition.

See Also
The **NewFIFO** and **FIFO2Wave** operations, and **FIFOs and Charts** on page IV-276.

Cursor

```
Cursor [flags] cursorName traceName x_value
Cursor /F[flags] cursorName traceName x_value, y_value
Cursor /K[/W=graphName] cursorName
Cursor /I[/F][flags] cursorName imageName x_value, y_value
Cursor /M[flags] cursorName
```

The Cursor operation moves the cursor specified by *cursorName* onto the named trace at the point whose X value is *x_value*. or the coordinates of an image pixel or free cursor position at *x_value* and *y_value*.

Parameters
cursorName is one of ten cursors A through J.

Flags

/A=*a* — Activates (*a*=1) or deactivates (*a*=0) the cursor. Active cursors move with arrow keys or the cursor panel.

/C=(*r*,*g*,*b*) — Sets the cursor color (default is black). *r*, *g*, and *b* specify the amount of red, green, and blue in the color of the waves as an integer from 0 to 65535.

/F — Cursor roams free. The trace or image provides the axis pair that defines x and y coordinates for the setting and readout. Use /P to set in relative coordinates, where 0,0 is the top left corner of the rectangle defined by the axes and 1,1 is the right bottom corner.

/H=*h* — Specifies crosshairs on cursors.

- *h*=0 Full crosshairs off.
- *h*=1 Full crosshairs on.
- *h*=2 Vertical hairline.
- *h*=3 Horizontal hairline.

/I — Places cursor on specified image.

/K — Removes the named cursor from the top graph.

/L=*lStyle* — Line style for crosshairs (full or small).

- *lStyle*=0: Solid lines.
- *lStyle*=1: Alternating color dash.

/M — Modifies properties without having to specify trace or image coordinates. Does not work with the /F or /I flags.

/P — Interpret *xNum* as a point number rather than an X value.

/S=*s* — Sets cursor style.

- *s*=0: Original square or circle.
- *s*=1: Small crosshair with letter.
- *s*=2: Small crosshair without letter.

/W=*graphName* — Specifies a particular named graph window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *graphName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details
Usually *traceName* is the same as the name of the wave displayed by that trace, but it could be a name in instance notation. See **ModifyGraph (traces)** and **Instance Notation** on page IV-16 for discussions of trace names and instance notation.

A string containing *traceName* can be used with the $ operator to specify the trace name.

x_value is an X value in terms of the X scaling of the wave displayed by *traceName*. If *traceName* is graphed as an XY pair, then *x_value* is *not* the same as the X axis coordinate. Since the X scaling is ignored when displaying an XY pair in a graph, we recommend you use the /P flag and use a point number for *x_value*.

cursorName is a name, *not* a string.

To get a cursor readout, choose ShowInfo from the Graph menu.

Moving a cursor in a macro or function does not immediately erase the old cursor. DoUpdate has to be explicitly called.

Examples

```
Display myWave                          // X coordinates from X scaling of myWave
Cursor A, myWave, leftx(myWave)         //cursor A on first point of myWave

AppendToGraph yWave vs xWave            //X coordinates from xWave, not X scaling
Cursor/P B,yWave,numpnts(yWave)-1       //cursor B on last point of yWave
DoUpdate                                // erase any old A or B cursors
```

CursorStyle

CursorStyle

CursorStyle is a procedure subtype keyword that puts the name of the procedure in the "Style function" submenu of the Cursor Info pop-up menu. It is automatically used when Igor creates a cursor style function. To create a cursor style function, choose "Save style function" in the "Style function" submenu of the Cursor Info pop-up menu.

CurveFit

CurveFit [*flags*] *fitType*, [**kwCWave=***coefWaveName*,] *waveName* [*flag parameters*]

The CurveFit operation fits one of several built-in functions to your data (for user-defined fits, see the **FuncFit** operation). When with CurveFit and built-in fit functions, automatic initial guesses will provide a good starting point in most cases.

The results of the fit are returned in a wave, by default W_coef. In addition, the results are put into the system variables K0, K1 … K*n* but the use of the system variables is limited and considered obsolete

You can specify your own wave for the coefficient wave instead of W_coef using the kwCWave keyword.

Virtually all waves specified to the CurveFit operation can be a sub-range of a larger wave using the same sub-range syntax as the Display operation uses for graphing. See **Wave Subrange Details** on page V-91.

See Chapter III-8, **Curve Fitting** for detailed information including the use of the Curve Fit dialog.

CurveFit operation parameters are grouped in the following categories: flags, fit type, parameters (kwCWave=*coefWaveName* and *waveName*), and flag parameters. The sections below correspond to these categories. Note that flags must precede the fit type and flag parameters must follow *waveName*.

Flags

/B=*pointsPerCycle*	Used when *type* is sin; *pointsPerCycle* is the estimated number of data points per sine wave cycle. This helps provide initial guesses for the fit. You may need to try a few different values on either side of your estimated points/cycle.
/C	Makes constraint matrix and vector. This only applies if you use the /C=*constraintSpec* parameter to specify constraints (see below). Creates the M_FitConstraint matrix and the W_FitConstraint vector. For more information, see **Fitting with Constraints** on page III-197.
/G	Use values in variables K0, K1 … K*n* as starting guesses for a fit. If you specify a coefficient wave with the kwCWave keyword, the starting guesses will be read from the coefficient wave.
/H="*hhh…*"	Specifies coefficients to hold constant. *h* is 1 for coefficients to hold, 0 for coefficients vary. For example, `/H="100"` holds K0 constant, varies K1 and K2.
/K={*constants*}	Sets values of constants (not fit coefficients) in certain fitting functions. For instance, the exp_XOffset function contains an X offset constant. Built-in functions will set the constant automatically, but the automatic value can be overridden using this flag.

constants is a list of constant values, e.g., /K={1,2,3}. The length of the list must match the number of constants used by the chosen fit function.

This flag is not currently supported by the Curve Fit dialog. Use the To Cmd button and add the flag on the command line.

/L=*destLen* Sets the length of the wave created by the AutoTrace feature, that is, /D without destination wave (see the /D parameter above). The length of the wave fit_*waveName* will be set to *destLen*. This keyword also sets the lengths of waves created for confidence and prediction bands.

/M Generates the covariance matrix, the waves CM_K*n*, where *n* is from 0 (for K0) to the number of coefficients minus one.

/M=*doMat* Generates the covariance matrix. If *doMat* =2, the covariance matrix is put into a 2D matrix wave called M_Covar. If *doMat* =1 or is missing, the covariance matrix is generated as the 1D waves CM_K*n*, where *n* is from 0 (for K0) to the number of coefficients minus one. If *doMat* =0, the covariance matrix is not generated. *doMat* =1 is included for compatibility with previous versions; it is better to use *doMat* =2.

/N[=*dontUpdate*] If *dontUpdate* = 1, suppresses updates during the fit. This can make the curve fit go much faster; all graphs, tables, etc. will be updated when the fit finishes. /N is the same as /N=1.

/NTHR = *nthreads* Uses multithreaded code in *nthreads* threads for built-in and standard user-defined fitting functions. Values for *nthreads* are:

0: Selects Auto mode, which uses a number of threads equal to the number of processors in your computer (see **ThreadProcessorCount**).

1: Uses one thread, that is, it is not multithreaded. Overhead for multithreaded code makes it pretty much useless for built-in functions. For user-defined functions you can get almost double the speed on a two-processor computer; the benefit will depend on how fast your fit function is, and how many data points you are fitting.

/O Generates only initial guesses; doesn't actually do the fit.

/ODR=*fitMethod* Selects a fitting method. Values for *fitMethod* are:

0: Default Levenberg-Marquardt least-squares method using old code.

1: Trust-region Levenberg-Marquardt ordinary least-squares method implemented using ODRPACK95 code. See **Curve Fitting References** on page III-231.

2: Trust-region Levenberg-Marquardt least orthogonal distance method implemented using ODRPACK95 code. This method is appropriate for fitting when there are measurement errors in the independent variables, sometimes called "errors in variables fitting", "random regressor models," or "measurement error models".

3: Implicit fit. No dependent variable is specified; instead fitting attempts to adjust the fit coefficients such that the fit function returns zero for all dependent variables.

Implicit fitting will be of almost no use with the built-in fitting functions. Instead, use **FuncFit** and a user-defined fit function designed for an implicit fit.

/Q[=*quiet*] If quiet = 1, prevents results from being printed in history. /Q is the same as /Q=1.

/TBOX = *textboxSpec* Adds an annotation to the graph containing the fit data (see the **TextBox** operation, or Chapter III-2, **Annotations**). The textbox contains a customizable set of information about the fit. The argument *textboxSpec* is a bitfield to select various elements to be included in the textbox:

textboxSpec	**Selects This Element**
1	Title "Curve Fit Results"
2	Date
4	Time

textboxSpec	Selects This Element
8	Fit Type (Least Squares, ODR, etc.)
16	Fit function name
32	Model Wave, the autodestination wave (includes a symbol for the trace if appropriate)
64	Y Wave, with trace symbol
128	X Wave
256	Coefficient value report
512	Include errors in the coefficient value report

Request inclusion of various parts by adding up the values for each part you want.

Setting *textboxSpec* to zero will remove the textbox. Default is *textboxSpec* = 0.

/X Sets the X scaling of the auto-trace destination wave to match the appropriate X axis on the graph when the Y data wave is on the top graph. This is useful when you want to extrapolate the curve outside the range of X data being fit.

/W=*wait* Specifies behavior for the curve fit results window.

wait=1 Wait till user clicks OK button before dismissing curve fit results window. This is the default behavior from the command line or dialog.

wait =0 Do not wait. This is the default behavior from a procedure.

wait =2 Do not display the curve fit results window at all. Use this when you are doing many curve fits in a loop. Requires Igor Pro 6.21 or later.

Fit Types

fitType is one of the built-in curve fit function types:

gauss Gaussian peak: $y = K_0 + K_1 \exp\left[-\left(\frac{x-K_2}{K_3}\right)^2\right]$.

lor Lorentzian peak: $y = K_0 + \frac{K_1}{(x-K_2)^2 + K_3}$.

exp Exponential: $y = K_0 + K_1 \exp(-K_2 x)$.

dblexp Double exponential: $y = K_0 + K_1 \exp(-K_2 x) + K_3 \exp(-K_4 x)$.

sin Sinusoid: $y = K_0 + K_1 \sin(K_2 x + K_3)$.

line Line: $y = K_0 + K_1 x$.

poly *n* Polynomial: $y = k_0 + K_1 x + K_2 x^2 + \ldots$.

n is from 3 to 20. *n* is the number of terms or the degree plus one.

poly_XOffset n Polynomial: y = K0+K1*(x-x_0)+K2*(x-x_0)^2+...

n is from 3 to 20. *n* is the number of terms or the degree plus one.

x_0 is a constant; by default it is set to the minimum X value involved in the fit. Inclusion of x_0 prevents problems with floating-point roundoff errors when you have large values of X in your data set.

hillequation Hill's Equation: $y = K_0 + \frac{(K_1 - K_0)}{1 + (K_3/x)^{K_2}}$.

This is a sigmoidal function. Note that X values must be greater than 0.

sigmoid $y = K_0 + \frac{K_1}{1 + \exp(K_2 - x/K_3)}$.

power — Power law: $y = K_0 + K_1 x^{K_2}$. Note that X values must be greater than 0.

lognormal — Log normal: $y = K_0 + K_1 \exp\left[-\left(\frac{\ln(x/K_2)}{K_3}\right)^2\right]$. X values must be greater than 0.

gauss2D — Two-dimensional Gaussian:

$$z = K_0 + K_1 \exp\left[\frac{-1}{2(1-K_6^2)}\left(\left(\frac{x-K_2}{K_3}\right)^2 + \left(\frac{y-K_4}{K_5}\right)^2 - \frac{2K_6(x-K_2)(y-K_4)}{K_3 K_5}\right)\right].$$

The cross-correlation coefficient (K_6) must be between -1 and 1. This coefficient is automatically constrained to lie in that range. If you are confident that the correlation is zero, it may greatly speed the fit to hold it at zero.

poly2D *n* — Two-dimensional polynomial: $z = K_0 + K_1 x + K_2 y + K_3 x^2 + K_4 xy + K_5 y^2 + \ldots$

where *n* is the degree of the polynomial. All terms up to degree *n* are included, including cross terms. For instance, degree 3 terms are x^3, x^2y, xy^2, and y^3.

exp_XOffset — Exponential: $y = K_0 + K_1 \exp(-(x - x_0)/K_2)$.

x_0 is a constant; by default it is set to the minimum *x* value involved in the fit. Inclusion of x_0 prevents problems with floating-point roundoff errors that can afflict the exp function.

dblexp_XOffset — Double exponential:

$$y = K_0 + K_1 \exp(-(x - x_0)/K_2) + K_3 \exp(-(x - x_0)/K_{4(2)}).$$

x_0 is a constant; by default it is set to the minimum *x* value involved in the fit. Inclusion of x_0 prevents problems with floating-point roundoff errors that can afflict the exp function.

Parameters

kwCWave=*coefWaveName* specifies an optional coefficient wave. If present, the specified coefficient wave is set to the final coefficients determined by the curve fit. If absent, a wave named W_coef is created and is set to the final coefficients determined by the curve fit.

If you use kwCWave=*coefWaveName* and you include the /G flag, initial guesses are taken from the specified coefficient wave.

waveName is the wave containing the Y data to be fit to the selected function *type*. You can fit to a subrange of the wave by supplying (*startX*,*endX*) after the wave name. Though not shown in the syntax description, you can also specify the subrange in points by supplying [*startP*,*endP*] after the wave name. See **Wave Subrange Details** on page V-91 for more information on subranges of waves in curve fitting.

If you are using one of the two-dimensional fit functions (gauss2D or poly2D) either *waveName* must name a matrix wave or you must supply a list of X waves via the /X flag.

Flag Parameters

These flag parameters must follow *waveName*.

/A=*appendResid* — *appendResid* =1 (default) appends the automatically-generated residual to the graph and *appendResid* =0 prevents appending (see /R[=*residwaveName*]). With *appendResid* =0, the wave is generated and filled with residual values, but not appended to the graph.

/AD[=*doAutoDest*] — If *doAutoDest* is 1, it is the same as /D alone. /AD is the same as /AD=1.

/C=*constraintSpec* — Applies linear constraints during curve fitting. Constraints can be in the form of a text wave containing constraint expressions (/C=*textWaveName*) or a suitable matrix and vector (/C={*constraintMatrix*, *constraintVector*}). See **Fitting with Constraints** on page III-197. **Note**: Constraints are not available for the built-in line, poly and poly2D fit functions. To apply constraints to these fit functions you must create a user-defined fit function.

/D [=*destwaveName*] — *destwaveName* is evaluated based on the equation resulting from the fit. *destwaveName* must have the same length as *waveName*.

If only /D is specified, an automatically named wave is created. The name is based on the *waveName* with "fit_" as a prefix. This automatically named wave will be appended (if necessary) to the top graph if *waveName* is graphed there. The X scaling of the fit_ wave is set from the range of x data used during the fit.

By default the length of the automatically-created wave is 200 points (or 2 points for a straight line fit). This can be changed with the /L flag.

If *waveName* is a 1D wave displayed on a logarithmic X axis, Igor also creates an X wave with values exponentially spaced. The name is based on *waveName* with "fitX_" as a prefix.

/F={*confLevel*, *confType* [, *confStyleKey* [, *waveName*…]]}

Calculates confidence intervals for a confidence level of *confLevel*. The value of *confLevel* must be between 0 and 1 corresponding to confidence levels of 0 to 100 per cent.

confType selects what to calculate:

1: Confidence bands for the model.

2: Prediction bands for the model.

4: Confidence intervals for the fit coefficients.

These values can be added together to select multiple options. That is, to select both a confidence band and fit coefficient confidence intervals, set *confType* to 5.

Confidence and prediction bands can be shown as waves contouring a given confidence level (use "Contour" for *confStyleKey*) or as error bars (use "ErrorBar" for *confStyleKey*). The default is Contour.

If no waves are specified, waves to contain the results are automatically generated and appended to the top graph (if the top graph contains the fitted data). See **Confidence Band Details** for details on the waves for confidence bands.

Note: Confidence bands and prediction bands are not available for multivariate curve fits.

/I [=*weightType*]

If *weightType* is 1, the weighting wave (see /W parameter) contains standard deviations. If *weightType* is 0, the weighting wave contains reciprocal of the standard deviation. If the /I parameter is not present, the default is /I=0.

/M=*maskWaveName*

Specifies that you want to use the wave named *maskWaveName* to select points to be fit. The mask wave must match the dependent variable wave in number of points and dimensions. Setting a point in the mask wave to zero or NaN (blank in a table) eliminates that point from the fit.

/R [=*residwaveName*]

Calculates elements of *residwaveName* by subtracting model values from the data values. *residwaveName* must have the same length as *waveName*.

If only /R is specified, an automatically named wave is created with the same number of points as *waveName*. The name is based on *waveName* with "Res_" as a prefix.

The automatically created residual wave will be appended (if necessary) to the top graph if *waveName* is graphed there. The residual wave is appended to a new free axis named by prepending "Res_" to the name of the vertical axis used for plotting *waveName*. To the extent possible, the new free axis is formatted nicely.

If the graph containing the data to be fit has very complex formatting, you may not wish to automatically append the residual to the graph. In this case, use /A=0.

/AR=*doAutoResid*

If *doAutoResid* is 1, it is the same as /R alone. /AR is the same as /AR=1.

/W=*wghtwaveName*

wghtwaveName contains weighting values applied during the fit, and must have the same length as *waveName*. These weighting values can be either the reciprocal of the standard errors, or the standard errors. See the /I parameter above for details.

/X=*xwaveName*

The X values for the data to fit come from *xwaveName*, which must have the same length and type as *waveName*.

If you are fitting to one of the two-dimensional fit functions and *waveName* is a matrix wave, *xwaveName* supplies independent variable data for the X dimension. In this case, *xwaveName* must name a 1D wave with the same number of rows as *waveName*.

/X={*xwave1*, *xwave2*}

For fitting to one of the two-dimensional fit functions when *waveName* is a 1D wave. *xwave1* and *xwave2* must have the same length as *waveName*.

/Y=*ywaveName*

For fitting using one of the 2D fit functions if *waveName* is a matrix wave. *ywaveName* must be a 1D wave with length equal to the number of columns in *waveName*.

/NWOK

Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to CurveFit is normally treated as an error. By using /NWOK, you are telling CurveFit that a null wave

reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls CurveFit with optional waves.

The waves affected are the X wave or waves (/X), weight wave (/W), mask wave (/M) and constraint text wave (/C). The destination wave (/D=wave) and residual wave (/R=wave) are also affected, but the situation is more complicated because of the dual use of /D and /R to mean "do autodestination" and "do autoresidual". See /AR and /AD.

If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.

Note: To work properly this flag must be the last one in the command.

Flag Parameters for Nonzero /ODR

/XW=*xWeightWave*

/XW={*xWeight1*, *xWeight2*}

/ODR=2 or 3 only.

Specifies weighting values for the independent variables using *xWeightWave*, which must have the same length as *waveName*. When fitting to one of the multivariate fit functions such as poly2D or Gauss2D, you must supply a weight wave for each independent variable using the second form.

Weighting values can be either the reciprocal of the standard errors, or the standard errors. The choice of standard error or reciprocal standard error must be the same for both /W and /XW. See /I for details.

/XHLD=*holdWave*

/XHLD={*holdWave1*, *holdWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to hold the values of the independent variables fixed during orthogonal distance regression. The waves must match the input X data; a one in a wave element fixes the value of the corresponding X value.

/CMAG=*scaleWave* Specifies a wave that indicates the expected scale of the fit coefficients at the solution. If different coefficients have very different orders of magnitude of expected values, this can improve the efficiency and accuracy of the fit.

/XD=*xDestWave*

/XD={*xDestWave1*, *xDestWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to receive the fitted values of the independent variables during a least orthogonal distance regression.

/XR=*xResidWave*

/XR={*xResidWave1*, *xResidWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to receive the differences between fitted values of the independent variables and the starting values during a least orthogonal distance regression. That is, they will be filled with the X residuals.

Details

CurveFit gets initial guesses from the K*n* system variables when user guesses (/G) are specified, unless a coefficient wave is specified using the kwCWave keyword. Final curve fit parameters are written into a wave name W_coef, unless you specify a coefficient wave with the kwCWave keyword.

Other output waves are M_Covar (see the /M flag), M_FitConstraint and W_FitConstraint (see /C parameter and **Fitting with Constraints** on page III-197) and W_sigma.

For compatibility with earlier versions of Igor, the parameters are also stored in the system variables Kn. This can be a source of confusion. We suggest you think of W_coef as the **output** coefficients and Kn as **input** coefficients that get overwritten.

Other output waves are M_Covar (see the /M flag), M_FitConstraint and W_FitConstraint (see /C parameter and **Fitting with Constraints** on page III-197), W_sigma. If you have selected coefficient confidence limits

using the /F parameter, a wave called W_ParamConfidenceInterval is created with the confidence intervals for the fit coefficients.

CurveFit stores other curve fitting statistics in variables whose names begin with "V_". CurveFit also looks for certain V_ variables which you can use to modify its behavior. These are discussed in **Special Variables for Curve Fitting** on page III-202.

When fitting with /ODR=nonzero, fitting with constraints is limited to simple "bound constraints." That is, you can constrain a fit coefficient to be greater than or less than some value. Constraints involving combinations of fit coefficients are supported only with /ODR=0. The constraints are entered in the same way, using an expression like `K0>1`.

Wave Subrange Details

Almost any wave you specify to CurveFit can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command (see **Subrange Display Syntax** on page II-288 for details). However, the Display command allows only one dimension to have a range (multiple elements from the dimension); if a multidimensional wave is appropriate for CurveFit, you may use a range for more than one dimension.

Some waves must have the same number of points as other waves. For instance, a one-dimensional Y wave must have the same number of points as any X waves. Thus, if you use a subrange for an X wave, the number of points in the subrange must match the number of points being used in the Y wave (but see **Subrange Backward Compatibility** on page V-92 for a complication to this rule).

A common use of wave subranges might be to package all your data into a single multicolumn wave, along with the residuals and model values. For a univariate fit, you might need X and Y waves, plus a destination (model) wave and a residual wave. You can achieve all of that using a four-column wave. For example:

```
Make/D/N=(100, 4) Data
... fill column zero with X data and column one with Y data ...
CurveFit poly 3, Data[][1] /X=Data[][0]/D=Data[][2]/R=Data[][3]
```

Note that because all the waves are full columns from a single multicolumn wave, the number of points is guaranteed to be the same.

The number of points used for X waves (*xwaveName* or {*xwave1*, *xwave2*, …}), weighting wave (*wghtwaveName*), mask wave (`maskWaveName`), destination wave (*destwaveName*) and residual wave (*residwaveName*) must be the same as the number of points used for the Y wave (*waveName*). If you specify your own confidence band waves (/F flag) they must match the Y wave; you cannot use subranges with confidence band waves. If you set /ODR = nonzero, the X weight, hold, destination and residuals waves must match the Y wave.

The total number of points in each wave does not need to match other waves, just the number of points in the specified subrange.

When fitting to a univariate fit function (that includes almost all the fit types) the Y wave must have effectively one dimension. That means the Y wave must either be a 1D wave, or it must have a subrange that makes the data being used one dimensional. For instance:

```
Make/N=(100,100) Ydata           // 2D wave
CurveFit gauss Ydata[][0]        // OK- a single column is one-dimensional
CurveFit gauss Ydata[2][]        // OK- s single row is one-dimensional
CurveFit gauss Ydata             // not OK- Ydata is two-dimensional
CurveFit gauss Ydata[][0,1]      // not OK- two columns makes 2D subrange
```

When fitting a multivariate function (**poly2D** or **Gauss2D**) you have the choice of making the Y data either one-dimensional or two-dimensional. If it is one-dimensional, then you must be fitting XYZ (or Y,X1,X2) triplets. In that case, you must provide a one-dimensional Y wave and two one-dimensional X waves, or 2 columns from a multicolumn wave. For instance:

These are OK:

```
Make/N=(100,3) myData
CurveFit Gauss2D myData[][0] /X={myData[][1],myData[][2]}
CurveFit Gauss2D myData[][0] /X=myData[][1,2]
```

These are not OK:

```
CurveFit Gauss2D myData /X={myData[][1],myData[][2]}// 2D Y wave with 1D X waves
CurveFit Gauss2D myData[][0] /X=myData            // too many X columns
```

If you use a 2D Y wave, the X1 and X2 data can come from the grid positions and the Y wave's X and Y index scaling, or you can use one-dimensional waves or wave subranges to specify the X1 and X2 positions of the grid:

```
Make/N=(20,30) yData
CurveFit Gauss2D yData        //OK- 2D Y data, X1 and X2 from scaling
Make/N=20 x1Data
Make/N=30 x2Data
// OK: 2D effective Y data, matching 1D X and Y flags
CurveFit Gauss2D yData[0,9][0,19] /X=x1Data[0,9]/Y=x2data[10,29]
// OK: effective 2D Y data
Make/N=(10,20,3) Y data
CurveFit Gauss2D yData[][][0]
```

There are, of course, lots of possible combinations, too numerous to enumerate.

Subrange Backward Compatibility

Historically, a Y wave could have a subrange. The same subrange applied to all other waves. For backward compatibility, if you use a subrange with the Y wave only, and other waves lack a subrange, these other waves must have either: 1) The same total number of points as the total number of points in the Y wave in which case the Y wave subrange will be applied; or 2) The same total number of points as the Y wave's subrange.

In addition, the Y wave can take a subrange in parentheses to indicate that the subrange refers to the Y wave's scaled indices (X scaling). If you use parentheses to specify an X range, you must satisfy the old subrange rules: All waves must have the same number of points. Subrange is allowed for the Y wave only. The Y wave subrange is applied to all other waves.

Confidence Band Details

Automatic generation of confidence and prediction bands occurs if the /F={…} parameter is used with no wave names. One to four waves are generated, or you can specify one to four wave names yourself depending on the *confKind* and *confStyle* settings.

Waves auto-generated by /F={*confLevel*, *confKind*, *confStyle*}:

confKind	*confStyle*	What You Get	Auto Wave Names
1	"Contour"	upper and lower confidence contours	UC_*dataName*, LC_*dataName*
2	"Contour"	upper and lower prediction contours	UP_*dataName*, LP_*dataName*
3	"Contour"	upper and lower confidence contours and prediction contours	UC_*dataName*, LC_*dataName*, UP_*dataName*, LP_*dataName*
1	"ErrorBar"	confidence interval wave	CI_*dataName*
2	"ErrorBar"	prediction interval wave	PI_*dataName*
3	"ErrorBar"	confidence and prediction interval waves	CI_*dataName*, PI_*dataName*

Note that *confKind* may have 4 added to it if you want coefficient confidence limits calculated as well.

The contour waves are appended to the top graph as traces if the data wave is displayed in the top graph. The wave names have *dataName* replaced with the name of the wave containing the Y data for the fit.

Waves you must supply for /F={*confLevel*, *confKind*, *confStyle*, *wave*, *wave*…}:

confKind	*confStyle*	You Supply
1	"Contour"	2 waves to receive upper and lower confidence contours.
2	"Contour"	2 waves to receive upper and lower prediction contours.
3	"Contour"	4 waves to receive upper and lower confidence and upper and lower prediction contours.
1	"ErrorBar"	1 wave to receive values of confidence band width.
2	"ErrorBar"	1 wave to receive values of prediction band width.
3	"ErrorBar"	2 waves to receive values of confidence and prediction band widths.

The waves you supply must have the same number of points as the dependent variable data wave. The band intervals will be calculated at the X values of the input data. These waves are not automatically appended to a graph; it is expected that you will display the contour waves as traces or use the error bar waves to make error bars on the model fit wave.

Residual Details

Residuals are calculated only for elements corresponding to elements of waveName that are included in the fit. Thus, you can calculate residuals automatically for a piecewise fit done in several steps.

The automatic residual wave will be appended to the top graph if the graph displays the Y data. It is appended to a new free axis positioned directly above the axis used to display the Y data, making a stacked graph. Other axes are shortened as necessary to make room for the new axis. You can alter the axis formatting later. See **Creating Stacked Plots** on page II-293 for details.

While Igor will go to some lengths to make a nicely formatted stacked graph, the changes made to the graph formatting may be undesirable in certain cases. Use /A=0 to suppress the automatic append to the graph. The automatic residual wave will be created and filled with residual values, but not appended to the graph.

When fitting to a user-specified function, see **FuncFit**. For multivariate user-specified fitting functions, see **FuncFit** and **FuncFitMD**. See **Confidence Bands and Coefficient Confidence Intervals** on page III-194 for a detailed description of confidence and prediction bands.

References

An explanation of the Levenberg-Marquardt nonlinear least squares optimization can be found in Chapter 14.4 of Press, William H., *et al*., *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

CustomControl

`CustomControl [/Z] ctrlName [keyword = value [, keyword = value …]]`

The CustomControl operation creates or modifies a custom control in the target window. A CustomControl starts out as a generic button, but you can customize both its appearance and its action.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the CustomControl to be created or changed. See **Button** for standard default parameters.

The following keyword=value parameters are supported:

fColor=(*r*,*g*,*b*) Sets color of the button only when picture is not used and frame=1.

r, *g*, and *b* can range from 0 to 65535.

frame= f Sets frame style used only when picture is not used:

- f =0: No frame (only the title is drawn).
- f =1: Default, a button is drawn with a centered title. Set fColor to something other than black to colorize the button.
- f =2: Simple box.
- f =3: 3D sunken frame. On Macintosh, when "native GUI appearance" is enabled for the control, the frame is filled with the proper operating system color.
- f =4: 3D raised frame.
- f =5: Text well.

labelBack=(*r*,*g*,*b*) or 0

Sets background color for the control only when a picture is not used and frame is not 1 and is not 3 on Macintosh.

r, *g* and *b* specify the amount of red, green and blue in the color as an integer from 0 to 65535. If not set (or labelBack=0), then background is transparent (not erased).

mode=*m* Notifies the control that something has happened. Can be used for any purpose. See **Details** discussion of the `kCCE_mode` event.

noproc Specifies that no procedure will execute when clicking the custom control.

picture= *pict* Uses the named Proc Pictures to draw the control. The picture is taken to be three side-by-side frames, which show the control appearance in the normal state, when the mouse is down, and in the disabled state.

The control action function can overwrite the picture number using the picture={*pict*,*n*} syntax.

The picture size overrides the size keyword.

picture={*pict*,*n*} Uses the specified Proc Picture to draw the control. The picture is *n* side-by-side frames instead of the default three frames.

pos={*left*,*top*} Sets the postion of the control in pixels.

pos+={*dx*,*dy*} Offsets the position of the control in pixels.

proc=*procName* Specifies the name of the action function for the control. The function must not kill the control or the window.

size={*width*,*height*} Sets size of the control in pixels but only when not using a Proc Picture.

title=*titleStr* Specifies text that appears in the control.

titleStr can contain formatting escape codes in order to create fancy, styled results. The escape codes are the same as used by the **TextBox** operation. The easiest way to generate fancy text is to create a dummy TextBox, set up the text as desired, click the To Cmd Line button, and then edit the TextBox command for use with the control.

userdata(*UDName*)=*UDStr*
Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

userdata(*UDName*)+=*UDStr*
Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

value=*varName* Sets the numeric variable, string variable, or wave that is associated with the control. With a wave, specify a point using the standard bracket notation with either a point number (`value=awave[4]`) or a row label (`value=awave[%alabel]`).

valueColor=(*r*,*g*,*b*) Sets initial color of the title for the button drawn only when picture is not used and frame=1.

r, *g*, and *b* range from 0 to 65535. *valueColor* defaults to black (0,0,0). To further change the color of the title text, use escape sequences as described for title=*titleStr*.

Flags

/Z No error reporting.

Details

When you create a custom control, your action procedure will need to get information about the state of the control using the `WMCustomControlAction` structure, which is a predefined structure passed to your function. All of the various members of the `WMCustomControlAction` structure are as described in the following tables:

Base `WMCustomControlAction` Structure Members

Member	Description
`char ctrlName[MAX_OBJ_NAME+1]`	Control name.
`char win[MAX_WIN_PATH+1]`	Host (sub)window.
`STRUCT Rect winRect`	Local coordinates of host window.
`STRUCT Rect ctrlRect`	Enclosing rectangle of the control.
`STRUCT Point mouseLoc`	Mouse location.
`Int32 eventCode`	Event that caused the procedure to execute.
`Int32 eventMod`	Bitfield of modifiers. See **Control Structure eventMod Field** on page III-385.
`String userData`	Primary (unnamed) user data. When this is changed, it is automatically written back.
`Int32 blockReentry`	Prevents reentry of control action procedure. See **Control Structure blockReentry Field** on page III-386.

Base WMCustomControlAction Structure Members

Member	Description
Int32 missedEvents	TRUE when events occurred but the user function was not available for action.
Int32 mode	General purpose.
Int32 curFrame	Input and output, used with kCCE_frame event.
Int32 needAction	Action meaning depends on the event: Events kCCE_mousemoved, kCCE_enter, and kCCE_leave set to TRUE to force redraw, which is normally not done for these events. Event kCCE_tab and kCCE_mousedown set to TRUE to request keyboard focus (and get kCCE_char events). Event kCCE_idle set to TRUE to request redraw.

Members of WMCustomControlAction Structure with value=*varName*

Member	Description
Int32 isVariable	TRUE if *varName* is a numeric variable or a string variable.
Int32 isWave	TRUE if *varName* referenced a wave.
Int32 isString	TRUE if *varName* is a String type.
NVAR nVal	If isVariable and not isString.
SVAR sVal	If isVariable and isString.
WAVE nWave	If isWave and not isString.
WAVE/T sWave	If isWave and not isString.
Int32 rowIndex	If isWave, this is the row index if rowLabel is empty.
char rowLabel[MAX_OBJ_NAME+1]	Wave row label.

Members of WMCustomControlAction Structure with kCCE_char

Member	Description
Int32 kbChar	Keyboard key character code.
Int32 kbMods	Keyboard key modifiers bit field: bit 0: Command (*Macintosh*). bit 1: Shift. bit 2: Alpha Lock. bit 3: Option (*Macintosh*) or Alt (*Windows*). bit 4: Control.

When determining the state of the eventCode member in the WMCustomControlAction structure, the various code values you use are defined in this section.

When determining the state of the eventCode member in the WMCustomControlAction structure, the various values you use are specified below. You can define them as static constants in your procedure file or, in Igor Pro 6.20 or later, define them by adding this include statement to your procedure file:

```
#include <CustomControl Definitions>
```

Event Code	Description
kCCE_mousedown = 1	Mouse down in control.
kCCE_mouseup = 2	Mouse up in control.
kCCE_mouseup_out = 3	Mouse up outside control.
kCCE_mousemoved = 4	Mouse moved (happens only when mouse is over the control).
kCCE_enter = 5	Mouse entered control.
kCCE_leave = 6	Mouse left control.
kCCE_draw = 10	Time to draw custom content.
kCCE_mode = 11	Sent when executing CustomControl *name*, mode=*m*.
kCCE_frame = 12	Sent before drawing a subframe of a custom picture.
kCCE_dispose = 13	Sent as the control is killed.
kCCE_modernize = 14	Sent when dependency (variable or wave set by value=*varName* parameter) fires. It will also get draw events, which probably don't need a response.
kCCE_tab = 15	Sent when user tabs into the control. If you want keystrokes (kCCE_char), then set needAction.
kCCE_char = 16	Sent on keyboard events. Stores the keyboard character in kbChar and modifiers bit field is stored in kbMods. Sets needAction if key event was used and requires a redraw.
kCCE_drawOSBM = 17	Called after drawing *pict* from picture parameter into an offscreen bitmap. You can draw custom content here.
kCCE_idle = 18	Idle event typically used to blink insertion points etc. Set needAction to force the control to redraw. Sent only when the host window is topmost.

When you call a function with the kCCE_draw event, the basic button picture (custom or default) will already have been drawn. You can use standard draw commands such as **DrawLine** to draw on top of the basic picture. Unlike the normal situation when draw commands merely add to a draw list, which only later is drawn, kCCE_draw event draw commands are executed directly. The coordinate system, which you can not change, is pixels with (0,0) being the top left corner of the control. Most drawing commands are legal but because of the immediate nature of drawing, the /A (append) flag of **DrawPoly** is not allowed.

The kCCE_mode event can be used for any purpose, but it mainly serves as a notification to the control that something has happened. For example, to send information to a control, you can set a named (or the unnamed) userdata and then set the mode to indicate that the control should examine the userdata. For this signaling purpose, you should use a mode value of 0 because this value will not become part of the recreation macro.

The kCCE_frame event is sent just before drawing one of the *pict* frames, as set by the picture parameter. On input, the curFrame field is set to 0 (normal or mouse down outside button), to 1 (mouse down in button), or to 2 (disable). You may modify curFrame as desired but your value will be clipped to a valid value.

When you specify a *pict* with the picture parameter, you will get a kCCE_drawOSBM event when that *pict* is drawn into an offscreen bitmap. Once it is created, all updates use the offscreen bitmap until you specify a new picture parameter. Thus the custom drawing done at this event is static, unlike drawing done during the kCCE_draw event, which can be different each time the control is drawn. Because the *pict* can be contain multiple side-by-side frames, the width of the offscreen bitmap is the width derived from the ctrlRect field multiplied by the number of frames.

Because the action function is called in the middle of various control events, it must not kill the control or the window. Doing so will almost certainly cause a crash.

Examples

See **CustomControl** on page III-371 for some examples of custom controls.

For a demonstration of custom controls, see the Custom Control Demo.pxp example experiment, which is located in your Igor Pro Folder in the Examples:Testing & Misc: folder.

See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Proc Pictures on page IV-43.

The **TextBox**, **DrawPoly** and **DefaultGUIControls** operations.

CWT

CWT [***flags***] ***srcWave***

The CWT operation computes the continuous wavelet transform (CWT) of a 1D real-valued input wave (*srcWave*). The input can be of any numeric type. The computed CWT is stored in the wave M_CWT in the current data folder. M_CWT is a double precision 2D wave which, depending on your choice of mother wavelet and output format, may also be complex. The dimensionality of M_CWT is determined by the specifications of offsets and scales. The operation sets the variable V_flag to zero if successful or to a nonzero number if it fails for any reason.

Flags

/ENDM=*method* Selects the method used to handle the two ends of the data array with direct integration (/M=1).

method=0: Padded on both sides by zeros.

method=1: Reflected at both the start and end.

method=2: Entered with cyclical repetition.

/FSCL Use correction factor to the wave scaling of the second dimension of the output wave so that the numbers are more closely related to Fourier wavelength. See **References** for more information on the calculation of these correction factors. This flag does not affect the output from the Haar wavelet.

/M=*method* Specifies the CWT computation method.

method=0: Fast method uses FFT (default).

method=1: Slower method using direct integration.

You should mostly use the more efficient FFT method. The direct method should be reserved to situations where the FFT is not producing optimal results. Theoretically, when the FFT method fails, the direct method should also be fairly inaccurate, e.g., in the case of undersampled signal. The main advantage in the direct method is that you can use it to investigate edge effects.

/OUT=*format* Sets the format of the output wave M_CWT:

format=1: Complex.

format=2: Real valued.

format=4: Real and contains the magnitude.

Depending on the method of calculation and the choice of mother wavelet, the "native" output of the transform may be real or complex. You can force the output to have a desired format using this flag.

/Q quiet mode; no results printed to the history.

/R1={*startOffset*, *delta1*, *numOffsets*}

Specifies offsets for the CWT. Offsets are the first dimension in a CWT. Normally you will calculate the CWT for the full range of offsets implied by *srcWave* so you will not need to use this flag. However, when using the slow method, this flag restricts the output range of offsets and save some computation time. *startOffset* (integer) is the point number of the first offset in *srcWave*. *delta1* is the interval between two consecutive CWT offsets. It is expressed in terms of the number *srcWave* points. *numOffsets* is the number of offsets for which the CWT is computed.

By default *startOffset*=0, *delta1*=1, and *numOffsets* is the number of points in *srcWave*. If you want to specify just the *startOffset* and *delta1*, you can set *numOffsets*=0 to use the same number of points as the source wave.

/R2={*startScale*, *scaleStepSize*, *numScales*}

Specifies the range of scales for the CWT is computation. Scales are the second dimension in the output wave. Note however that there are limitations on the minimum and maximum scales having to do with the sampling of your data. Because there is a rough correspondence between a Fourier spatial frequency and CWT scale it should be understood that there is also a maximum theoretical scale. This is obvious if you compute the CWT using an FFT but it also applies to the slow method. If you specify a range outside the allowed limits, the corresponding CWT values are set to NaN.

Use NaN if you want to use the default value for any parameter.

The default value for *startScale* is determined by sampling of the source wave and the wavelet parameter or order.

At a minimum you must specify either *scaleStepSize* or *numScales*.

/SMP1=*offsetMode* Determines computation of consecutive offsets. Currently supporting only *offsetMode*=1 for linear, user-provided partial offset limits (see /R1 flag): `val1=startOffset+numOffsets*delta1`.

/SMP2=*scaleMode* Determines computation of consecutive scales. *scaleMode* is 1 by default if you specify the /R2 flag.

scaleMode=1: Linear:

```
theScale=startScale+index*scaleStepSize
```

scaleMode=2: User-provided scaling wave.

scaleMode=4: Power of 2 scaling interval:

```
theScale=startScale*2.^(index*scaleStepSize)
```

When using *scaleMode*=4 the operation saves the consecutive scale values in the wave W_CWTScaling. Note also that if you use *scaleMode*=4 without specifying a corresponding /R2 flag, the default *scaleStepSize* of 1 and 64 scale values gives rise to scale values that quickly exceed the allowed limits.

(See /R2 flag for details about the different parameters used in the equations above.)

/SW2=*sWave* Provides specific scale values at which the transform is evaluated. Use instead of /R2 flag. It is your responsibility to make sure that the entries in the wave are appropriate for the sampling density of *srcWave*.

/WBI1={*Wavelet* [, *order*]}

Specifies the built-in wavelet (mother) function. *Wavelet* is the name of a wavelet function: Morlet (default), MorletC (complex), Haar, MexHat, DOG, and Paul.

Morlet: $\Psi_0(x) = \frac{1}{\Pi^{1/4}}\cos(\omega x)e^{-x^2/2}$.

By default, ω=5. Use the /WPR1 flag to specify other values for ω.

MorletC: $\Psi_0(x) = \frac{1}{\Pi^{1/4}}e^{i\omega x}e^{-x^2/2}$.

By default, ω=5. Use the /WPR1 flag to specify other values for ω.

Haar: $\Psi_0(x) = \begin{cases} 1 & 0 \le x < 0.5 \\ -1 & 0.5 \le x < 1 \end{cases}$.

DOG: $\Psi_0(m,x) = \frac{(-1)^{m+1}}{\sqrt{\Gamma\left(m+\frac{1}{2}\right)}}\ \frac{\mathrm{d}^m}{\mathrm{d}x^m}(e^{-x^2/2})$.

MexHat: special case of DOG with *m*=2.

Paul: $\Psi_0(m,x) = \frac{2^m i^m m!}{\sqrt{\pi(2m)!}}\ (1-ix)^{-(m+1)}$.

order applies to DOG and Paul wavelets only and specifies *m*, the particular member of the wavelet family.

The default wavelet is the Morlet.

/WPR1={*param1*} *param1* is a wavelet-specific parameter for the wavelet function selected by /WBI1. For example, use /WPR1={6} to change the Morlet frequency from the default (5).

/Z No error reporting. If an error occurs, sets V_flag to -1 but does not halt function execution.

Details

The CWT can be computed directly from its defining integral or by taking advantage of the fact that the integral represents a convolution which in turn can be calculated efficiently using the fast Fourier transform (FFT).

When using the FFT method one encounters the typical sampling problems and edge effects. Edge effects are also evident when using the slow method but they only significant in high scales.

From sampling considerations it can be shown that the maximum frequency of a discrete input signal is 1/2dt where dt is the time interval between two samples. It follows that the smallest CWT scale is 2dt and the largest scale is Ndt where N is the total number of samples in the input wave.

The transform in M_CWT is saved with the wave scaling. *startOffset* and *delta1* are used for the X-scaling. Both *startOffset* and *delta1* are either specified by the /R1 flag or copied from *srcWave*. The Y-scaling of M_CWT depends on your choice of /SMP2. If the CWT scaling is linear then the wave scaling is based on *startScale* and *scaleStepSize*. If you are using power of 2 scaling interval then the Y wave scaling of M_CWT has a *start*=0 and *delta*=1 and the wave W_CWTScaling contains the actual scale values for each column of M_CWT. Note that W_CWTScaling has one extra data point to make it suitable for display using an operation like:

```
AppendImage M_CWT vs {*, W_CWTScaling}
```

We have encountered two different definitions for the Morlet wavelet in the literature. The first is a complex function (MorletC) and the second is real (Morlet). Instead of choosing one of these definitions we implemented both so you may choose the appropriate wavelet.

See Also

For discrete wavelet transforms use the **DWT** operation. The **WignerTransform** and **FFT** operations.

For further discussion and examples see **Continuous Wavelet Transform** on page III-246.

References

Torrence, C., and G.P. Compo, A Practical Guide to Wavelet Analysis, *Bulletin of the American Meteorological Society*, *79*, 61-78, 1998.

The Torrence and Compo paper is also online at:
<http://paos.colorado.edu/research/wavelets/>.

DataFolderDir

DataFolderDir(*mode* [, *dfr*])

The DataFolderDir function returns a string containing a listing of some or all of the objects contained in the current data folder or in the data folder referenced by *dfr*. The *dfr* parameter was added in Igor Pro 6.20.

Parameters

mode is a bitwise flag for each type of object. Use -1 for all types. Use a sum of the bit values for multiple types.

Desired Type	Bit Number	Bit Value
All		-1
Data folders	0	1
Waves	1	2
Numeric variables	2	4
String variables	3	8

dfr is a data folder reference.

Details

The returned string has the following format:

FOLDERS:*name*,*name*,…;<CR>

WAVES:*name*,*name*,…;<CR>

VARIABLES:*name*,*name*,…;<CR>

STRINGS:*name*,*name*,…;<CR>

Where <CR> represents the carriage return character.

Tip

This function is mostly useful during debugging, used in a **Print** command. For finding the contents of a data folder programmatically, it will be easier to use the functions **CountObjects** and **GetIndexedObjName**.

Examples

```
Print DataFolderDir(8+4)      // prints variables and strings
Print DataFolderDir(-1)       // prints all objects
```

See Also

Chapter II-8, **Data Folders**.

Setting Bit Parameters on page IV-12 for information about bit settings.

DataFolderExists

DataFolderExists(*folderNameStr*)

The DataFolderExists function returns the truth that the specified data folder exists.

You can use a full or partial path to the data folder.

See Also

Chapter II-8, **Data Folders**.

DataFolderRefsEqual

DataFolderRefsEqual(*dfr1, dfr2*)

The DataFolderRefsEqual function returns the truth the two data folder references are the same.

Requires Igor Pro 6.20 or later.

See Also

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-61.

The **DataFolderRefStatus** function.

DataFolderRefStatus

DataFolderRefStatus(*dfr*)

The DataFolderRefStatus function returns the status of a data folder reference.

Requires Igor Pro 6.1 or later.

Details

DataFolderRefStatus returns zero if the data folder reference is invalid or non-zero if it is valid.

DataFolderRefStatus returns a bitwise result with bit 0 indicating if the reference is valid and bit 1 indicating if the reference data folder is free. Therefore the returned values are:

0: The data folder reference is invalid.

1: The data folder reference refers to a regular global data folder.

3: The data folder reference refers to a free data folder.

A data folder reference is invalid if it was never assigned a value or if it is assigned an invalid value. For example:

```
DFREF dfr                                   // dfr is invalid
DFREF dfr = root:                           // dfr is valid
DFREF dfr = root:NonExistentDataFolder      // dfr is invalid
```

A data folder reference can be valid and yet point to a non-existent data folder:

```
NewDataFolder/O root:MyDataFolder
DFREF dfr = root:MyDataFolder               // dfr is valid
KillDataFolder root:MyDataFolder            // dfr is still valid
```

After the KillDataFolder, dfr is still a valid data folder reference but points to a non-existent data folder.

You should use DataFolderRefStatus to test any DFREF variables that might not be valid, such as after assigning a reference when you are not sure that the referenced data folder exists. For historical reasons, an invalid DFREF variable will often act like root.

See Also

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-61.

dateToJulian

dateToJulian(*year, month, day*)

The dateToJulian function returns the Julian day number for the specified date. The Julian day starts at noon. Use negative number for BC years and positive numbers for AD years. To exclude any ambiguity, there is no year zero in this calendar. For general orientation, Julian day 2450000 corresponds to October 9, 1995.

See Also

The **JulianToDate** function.

For more information about the Julian calendar see: <http://www.tondering.dk/claus/cal/>.

date

date()

The date function returns a string containing the current date.

Formatting of dates depends on your operating system and on your preferences entered in the Date & Time control panel (*Macintosh*) or the Regional Settings control panel (*Windows*).

Examples

```
Print date()        // Prints Mon, Mar 15, 1993
```

See Also

The **Secs2Date**, **Secs2Time**, and **time** functions.

date2secs

date2secs(*year, month, day*)

The date2secs function returns the number of seconds from midnight on 1/1/1904 to the specified date.

Note that the month and day parameters are one-based, so these series start at one.

If *year*, *month*, and *day* are all -1 then date2secs returns the offset in seconds from the local time to the UTC (Universal Time Coordinate) time.

Examples

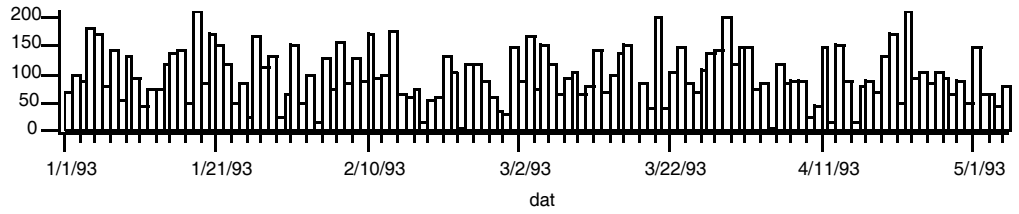
```
Print Secs2Date(date2secs(1993,3,15),1)        // Ides of March, 1993
```

Prints the following, depending on your system's date settings, in the history area:

```
  Monday, March 15, 1993
```

This next example sets the X scaling of a wave to 1 day per point, starting January 1, 1993:

```
Make/N=125 myData = 100 + gnoise(50)
SetScale/P x,date2secs(1993,1,1),24*60*60,"dat",myData
Display myData;ModifyGraph mode=5
```



See Also

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-102.

The **Secs2Date**, **Secs2Time**, and **time** functions.

DateTime

DateTime

The DateTime function returns number of seconds from 1/1/1904 to current date and time.

Unlike most Igor functions, DateTime is used without parentheses.

Examples

```
Variable now = DateTime
```

See Also

The **Secs2Date**, **Secs2Time** and **time** functions.

dawson

dawson(*x*)

The dawson function returns the value of the Dawson integral:

$$F(x) = \exp(-x^2)\int_0^x \exp(t^2)dt.$$

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 298 pp., Dover, New York, 1972.

DDEExecute

DDEExecute(*refNum*, *cmdStr* [, *timeout*])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEExecute function sends a string of commands, *cmdStr*, to the server for execution. The format of the commands depends on the server application.

refNum is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEExecute returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

In some situations, you may want to use a zero *timeout* and then use DDEStatus to monitor when the server is finished. You would do this if the server might take a long time to accomplish the commands and you want Igor to continue working at the same time.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDEInitiate

DDEInitiate(*serverName, topicName*)

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEInitiate function opens a DDE session and returns a reference number for use by the rest of the DDE routines. Returns zero if failure.

If the desired application is not running, DDEInitiate will return zero. If this occurs, you can use the ExecuteScriptText operation to start the server application.

Refer to your application's documentation for the *serverName* and *topicName*. See the following example for usage with Excel.

Examples

```
Variable ch= DDEInitiate("excel","book1")
```

See Also

The **ExecuteScriptText** operation. For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDEPokeString

DDEPokeString(*refNum, itemString, string* [*, timeout*])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEPokeString function sends *string* to the server.

itemString is a string specifying the server application's DDE item name for the location into which to store the string. For example, `"R1C1"` specifies the first cell in an Excel spreadsheet.

refNum is the DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEPokeString returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDEPokeWave

DDEPokeWave(*refNum, itemString, wave* [*, timeout* [*, format*]])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEPokeWave function sends data from a *wave* to the server.

itemString is a string specifying the server application's DDE item name for the location into which to store the string. For example, `"R1C1:R10C10"` specifies a 10x10 block of cells in an Excel spreadsheet.

refNum is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEPokeWave returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the *timeout* period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *format* parameter can be 0 to send the data as tab-delimited text (default) or can be 1 to specify Microsoft's XLTable (excel) format. To specify *format* without specifying *timeout*, the latter may be completely missing (`,,`) or a `*` symbol may be used:

```
err= DDEPokeWave(ch,"R1C1:R10C10",*,1)
```

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

Examples

A session using Microsoft Excel:

```
Variable ch,err1,err2
ch= DDEInitiate("excel","book1")
```

```
Make/O/N=(5,5) jack= P+10*Q
err1= DDEPokeWave(ch,"R1C1:R5C5",jack)
err2= DDETerminate(ch)
```

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDERequestString

DDERequestString(*refNum, itemString* [*, timeout*])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDERequestString string function returns a string of requested data or null handle in case of failure.

itemString is a string specifying the server application's DDE item name for the data being requested. For example, `"R1C1"` specifies the first cell in an Excel spreadsheet.

refNum is a DDE session reference number returned by DDEInitiate to start a particular session.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDERequestWave

DDERequestWave(*refNum, itemString, destWave* [*, timeout*])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDERequestWave function loads a preexisting wave with data from the server. The provided destination wave, *destWave*, can be either text or numeric. Data from the server must be a tab delimited array. It is analyzed to determine the dimensions of the wave but the numeric type (or string type) of the wave is not changed.

itemString is a string specifying the server application's DDE item name for the requested data. For example, `"R1C1:R10C10"` specifies a 10x10 block of cells in an Excel spreadsheet.

refNum is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDERequestWave returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDEStatus

DDEStatus(*refNum*)

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEStatus function returns the status of the DDE session defined by *refNum* from a previous DDEInitiate.

Returns zero if *refNum* is not valid or if the session has been closed.

Returns nonzero if session is valid where the individual bits have the following meanings:

Bit 0: Set if the session is valid and not busy.

Bit 1: Set if waiting for an ack from the server for a previous DDEPoke or DDEExecute that timed out. (bit 0 and 1 are exclusive).

Bit 2: Set if the ack from the server for a previous poke or execute command was negative. Only applies to timed out commands.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDETerminate

DDETerminate(*refNum*)

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDETerminate function closes the DDE session defined by *refNum* from a previous DDEInitiate. Returns truth session was valid.

Pass zero to terminate all client sessions.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

Debugger

Debugger

The Debugger operation breaks into the debugger if it is enabled.

See Also

The Debugger on page IV-184 and the **DebuggerOptions** operation.

DebuggerOptions

DebuggerOptions [**enable=*en*, debugOnError=*doe*, NVAR_SVAR_WAVE_Checking=*nvwc***]

The DebuggerOptions operation programmatically changes the user-level debugger settings. These are the same three settings that are available in the Procedure menu (and the debugger source pane contextual menu)

Parameters

All parameters are optional. If none are specified, no action is taken, but the output variables are still set.

enable=*en* Turns the debugger on (*en*=1) or off (*en*=0).

If the debugger is disabled then the other settings are cleared even if other settings are on.

debugOnError=*doe* Turns Debugging On Error on or off.

doe=0: Disables Debugging On Error (see **Debugging on Error** on page IV-185).

doe=1: Enables Debugging On Error and also enables the debugger (implies enable=1).

NVAR_SVAR_WAVE_Checking=*nvwc*

Turns NVAR, SVAR, and WAVE checking on or off.

nvwc=0: Disables "NVAR SVAR WAVE Checking". See **Accessing Global Variables and Waves** on page IV-50 for more details.

nvwc=1: Enables this checking and also enables the debugger (implies enable=1).

Details

DebuggerOptions sets the following variables to indicate the Debugger settings that are in effect *after* the command is executed. A value of zero means the setting is off, nonzero means the setting is on.

```
V_enable            V_debugOnError      V_NVAR_SVAR_WAVE_Checking
```

See Also

The Debugger on page IV-184 and the **Debugger** operation.

default

default:

The default flow control keyword is used in switch and strswitch statements. When none of the case labels in the switch or strswitch match the evaluation expression, execution will continue with code following the default label, if it is present.

See Also

Switch Statements on page IV-34.

DefaultFont

DefaultFont [**/U**] "***fontName***"

The DefaultFont operation sets the default font to be used in graphs for axis labels, tick mark labels and annotations, and in page layouts for annotations.

Parameters

"fontName" should be a font name, optionally in quotes. The quotes are not required if the font name is one word.

Flags

/U Updates existing graphs and page layouts immediately to use the new default font.

DefaultGUIControls

DefaultGUIControls [**/Mac/W=*winName*/Win**] [***appearance***]

The DefaultGUIControls operation changes the appearance of user-defined controls.

Note: The recommended way to change the appearance of user-defined controls is to use the Miscellaneous Settings dialog's Native GUI Appearance for Controls checkbox in the Compatibility tab, which is equivalent to `DefaultGUIControls native` when checked, and to `DefaultGUIControls os9` when unchecked.

Use `DefaultGUIControls/W=`*winName* to override that setting for individual windows.

Parameters

appearance may be one of the following:

native Creates standard-looking controls for the current computer platform. This is the default in Igor Pro 6.02 or later.

os9 Igor Pro 5 appearance (quasi-Macintosh OS 9 controls that look the same on Macintosh and Windows).

default Inherits the window appearance from either a parent window or the experiment-wide default (only valid with /W).

Flags

/Mac Changes the appearance of controls only on Macintosh, and it affects the experiment whenever it is used on Macintosh.

/W=*winName* Affects the named window or subwindow. When omitted, sets an experiment-wide default. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

/Win Changes the appearance of controls only on Windows, and it affects the experiment whenever it is used on Windows.

Details

If *appearance* is not specified, nothing is changed. The current value for appearance is returned in S_value.

If *appearance* is specified the previous appearance value for the window- or experiment-wide default is returned in S_value.

With /W, the control appearance applies only to the specified window (Graph or Panel). If it is not used, then the settings are global to experiments on the current computer. **Tip**: Use `/W=#` to refer to the current active subwindow.

The /Mac and /Win flags specify the affected computer platform. If the current platform other than specified, then the settings are not used, but (if native or OS9) are remembered for use in window recreation

macros or experiment recreation. This means you can create an experiment that with different appearances depending on the current platform.

If neither /Mac nor /Win are used, it is implied by the current platform. To set native appearance on both platforms, use two commands:

```
DefaultGUIControls/W=Panel0/Mac native
DefaultGUIControls/W=Panel0/Win native
```

Note: The setting for DefaultGUIControls without /W is not stored in the experiment file; it is a user preference set by the Miscellaneous Settings dialog's Native GUI Appearance for Controls checkbox in the Compatibility tab. If you use DefaultGUIControls native or DefaultGUIControls os9 commands, the checkbox will not show the current state of the experiment-wide setting. Clicking Save Settings in the Miscellaneous Settings dialog will overwrite the DefaultGUIControls setting (but not the per-window settings).

In addition to the experiment-wide appearance setting and the window-specific appearance setting, an individual control's appearance can be set with the appropriate control command's appearance keyword (or a ModifyControl appearance keyword). A control-specific appearance setting overrides a window-specific appearance, which in turn overrides the experiment-wide appearance setting.

Although meant to be used before controls are created, calling DefaultGUIControls will update all open windows.

DefaultGUIControls does not change control fonts or font sizes, which means you can create controls that look "native-ish" without having to readjust their positions to avoid avoid shifting or overlap. However, the smooth font rendering that the Native GUI uses on Macintosh does change the length of text slightly, so some shifting will occur that affects mostly controls that were aligned on their right sides.

The native appearance affects the way that controls are drawn in **TabControl** and **GroupBox** controls.

TabControl Background Details

Unlike the os9 appearance which draws only an outline to define the tab region (leaving the center alone) the native tab appearance fills the tab region. Fortunately, TabControls are drawn before all other kinds of controls which allows enclosed controls to be drawn on top of a tab control regardless of the order in which the buttons are defined in the window recreation macro.

However the drawing order of native TabControls does matter: the top-most TabControls draws over other TabControls. (The top-most TabControl is listed last in the window recreation macro.) The os9 appearance allows a smaller (nested) TabControl to be underneath the later (enclosing) TabControl because tabs normally aren't filled. Converting these tabs to native appearance will cause nested tab to be hidden.

To fix the drawing order problem in an existing panel, turn on the drawing tools, select the arrow tool, right-click the enclosing TabControl, and choose Send to Back to correct this situation. If the TabControl itself is inside another TabControl, select that enclosing TabControl and also choose Send to Back, etc.

To fix the window recreation macro or function that created the panel, arrange the enclosing TabControl commands to execute before the commands that create the enclosed TabControls.

A natively-drawn TabControl draws any drawing objects that are entirely enclosed by the tab region so that it behaves the same as an os9 unfilled TabControl with drawing objects inside.

Groupbox Control Background Details

GroupBox controls, unlike TabControls, are not drawn before all other controls, so the drawing order always matters if the GroupBox specifies a background (fill) color and it contains other controls.

You may find that enabling native appearance hides some controls inside the GroupBox. They are probably underneath (before) the GroupBox in the drawing order.

To fix this in an existing panel, turn on the drawing tools, right-click on the GroupBox and choose Send to Back. To fix the window recreation macro or function that created the panel, arrange the GroupBox commands to execute before the commands that create the enclosed controls.

A natively-drawn GroupBox draws any drawing objects that are entirely enclosed by the box; an os9 filled GroupBox does not.

See Also

The **DefaultGUIFont**, **ModifyControl**, **Button**, **GroupBox**, and **TabControl** operations.

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

DefaultGUIFont

DefaultGUIFont [**/W=*winName* /Mac/Win**] ***group* = {*fNameStr*,*fSize*,*fStyle*}** [**,…**]

The DefaultGUIFont operation changes the default font for user-defined controls and other Graphical User Interface elements.

Parameters

fNameStr is the name of a font, *fSize* is the font size, and *fStyle* is a binary coded number with each bit controlling one aspect of the font style. See **Button** for details about these parameters.

group may be one of the following:

all	All controls
button	Button and default CustomControl
checkbox	CheckBox controls
tabcontrol	TabControl controls
popup	Affects the icon (not the title) of a PopupMenu control. The text in the popped state is set by the system and can not be changed. The title of a PopupMenu is affected by the all group but the icon text is not.
panel	Draw text in a panel.
graph	Overlay graphs. Size is used only if `ModifyGraph gfSize= -1`; style is not used.
table	Overlay tables.

Flags

/Mac	Changes control fonts only on Macintosh, and it affects the experiment whenever it is used on Macintosh.
/W=*winName*	Affects the named window or subwindow. When omitted, sets an experiment-wide default. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.
/Win	Changes control fonts only on Windows, and it affects the experiment whenever it is used on Windows.

Details

Although designed to be used before controls are created, calling DefaultGUIFont will update all affected windows with controls. This makes it easy to experiment with fonts. Keep in mind that fonts can cause compatibility problems when moving between machines or platforms.

The /Mac and /Win flags indicate the platform on which the fonts are to be used. If the current platform is not the one specified then the settings are not used but are remembered for use in window recreation macros or experiment recreation. This allows a user to create an experiment that will use different fonts depending on the current platform.

If the /W flag is used then the font settings apply only to the specified window (Graph or Panel.) If the /W flag is not used, then the settings are global to the experiment. Tip: Use `/W=#` to refer to the current active subwindow.

fNameStr may be an empty string (`""`) to clear a group. Setting the font name to `"_IgorSmall"`, `"_IgorMedium"`, or `"_IgorLarge"` will use Igor's own defaults. The standard defaults for controls are the equivalent to setting all to `"_IgorSmall"`, tabcontrol to `"_IgorMedium"`, and button to `"_IgorLarge"`. Use a *fSize* of zero to also get the standard default for size. On Windows, the three default fonts and sizes are all the same.

Although designed to be used before controls are created, calling DefaultGUIFont will update all affected windows with controls. This makes it easy to experiment with fonts. Keep in mind that fonts can cause compatibility problems when moving between machines or platforms.

To read back settings, use `DefaultGUIFont [/W=`*winName*`/Mac/Win/OVR] `*group* to return the current font name in S_name, the size in V_value, and the style in V_flag. With /OVR or if /Mac or /Win is not current, it returns only override values. Otherwise, values include Igor built-in defaults. If S_name is zero length, values are not defined.

Default Fonts and Sizes

The standard defaults for controls is the equivalent to setting all to `"_IgorSmall"`, tabcontrol to `"_IgorMedium"`, and button to `"_IgorLarge"`. Use a *fSize* of zero to also get the standard default for size. On Windows, the three default fonts and sizes are all the same.

	Macintosh		Windows	
Control	**Font**	**Font Size**	**Font**	**Font Size**
Button	Lucida Grande	13	MS Shell Dlg*	12
Checkbox	Geneva	9	MS Shell Dlg	12
GroupBox	Geneva	9	MS Shell Dlg	12
ListBox	Geneva	9	MS Shell Dlg	12
PopupMenu†	Geneva	9	MS Shell Dlg	12
SetVariable	Geneva	9	MS Shell Dlg	12
Slider	Geneva	9	MS Shell Dlg	12
TabControl	Geneva	12	MS Shell Dlg	12
TitleBox	Geneva	9	MS Shell Dlg	12
ValDisplay	Geneva	9	MS Shell Dlg	12

* MS Shell Dlg is a "virtual font name", which usually maps to Tahoma on Windows.

† PopupMenu font for the title is Geneva 9 on Macintosh, for the popup menu itself the font is Lucida Grande 12. On Windows, both fonts are MS Shell Dlg 12.

Examples

```
DefaultGUIFont/Mac all={"Zapf Chancery",12,0},panel={"geneva",12,3}
DefaultGUIFont/Win all={"Century Gothic",12,0},panel={"arial",12,3}
NewPanel
Button b0
DrawText 40,43,"Some text"
```

See Also

The **DefaultGUIControls** operation. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

The example experiment: All Controls Demo.pxp.

defined

defined(*symbol*)

The defined function returns 1 if the symbol is defined 0 if the symbol is not defined.

symbol is a symbol possibly created by a #define statement or by SetIgorOption poundDefine=*symbol*.

symbol is a name, not a string. However you can use $ to convert a string expression to a name.

Details

The defined function can be used in three ways:

Outside of a procedure using a #if statement

Inside a procedure using a #if statement

Inside a procedure using an if statement

For example:

```
#define DEBUG

#if defined(DEBUG)                    // Outside of a function with #if
    Constant kSomeConstant = 100
#else
    Constant kSomeConstant = 50
```

```
#endif

Function Test1()                        // Inside a function with #if
    #if defined(DEBUG)
        Print "Debugging"
    #else
        Print "Not debugging"
    #endif
End

Function Test1()                        // Inside a function with if
    if (defined(DEBUG))
        Print "Debugging"
    else
        Print "Not debugging"
    endif
End
```

In these examples, we could have just as well used #ifdef instead of the defined function. For logical combinations of conditions however, only defined will do:

```
#if (defined(SYMBOL1) && defined(SYMBOL2)
    . . .
#endif
```

When used in a procedure window, defined(symbol) returns 1 if symbol is defined at the time the line is compiled. In a given procedure file, only the following symbols are visible:

Symbols defined earlier in that procedure file *

Symbols defined in the built-in procedure window †

Predefined symbols (see **Predefined Global Symbols** on page IV-87)

Symbols defined by **SetIgorOption** poundDefine=*symbol*

* When used in the body of a procedure, as opposed to outside of a procedure, a symbol defined anywhere in a given procedure window is visible. However, to avoid depending on this confusing exception, you should define all symbols before they are referenced in a procedure file.

† Symbols defined in the built-in procedure window are not available to independent modules.

When the defined function is used from the command line, only symbols defined in the built-in procedure window, predefined symbols, and symbols defined using SetIgorOption are visible.

The defined function was added for Igor 6.20.

See Also

#**define**, **Conditional Compilation** on page IV-86, **Predefined Global Symbols** on page IV-87

DefineGuide

DefineGuide [**/W=** ***winName***] ***newGuideName*** **=** **{**[***guideName1***, ***val*** [**,** ***guideName2***]]**}** [**,**…]

The DefineGuide operation creates or overwrites a user-defined guide line in the target or named window or subwindow. Guide lines help with the positioning of subwindows in a host window.

Parameters

newGuideName is the name for the newly created guide. When it is the name of an existing guide, the guide will be moved to the new position.

guideName1, *guideName2*, etc., must be the names of existing guides.

The meaning of *val* depends on the form of the command syntax. When using only one guide name, *val* is an absolute distance offset from to the guide. The directionality of *val* is to the right or below the guide for positive values. The units of measure are points except in panels where they are in pixels. When using two guide names, *val* is the fractional distance between the two guides.

Flags

/W=winName Defines guides in the named window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The names for the built-in guides are as defined in the following table:

	Left	Right	Top	Bottom
Host Window Frame	FL	FR	FT	FB
Host Graph Rectangle	GL	GR	GT	GB
Inner Graph Plot Rectangle	PL	PR	PT	PB

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows.

To delete a guide use *guideName*={}.

See Also

The **Display**, **Edit**, **NewPanel**, **NewImage**, and **NewWaterfall** operations.

The **GuideInfo** function.

DelayUpdate

DelayUpdate

The DelayUpdate operation delays the updating of graphs and tables while executing a macro.

Details

Use DelayUpdate at the end of a line in a macro if you want the next line in the macro to run before graphs or tables are updated.

This has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the **DoUpdate** operation.

See Also

The **DoUpdate**, **PauseUpdate**, and **ResumeUpdate** operations.

DeleteFile

DeleteFile [*flags*] [*fileNameStr*]

The DeleteFile operation deletes a file on disk.

Parameters

fileNameStr can be a full path to the file to be deleted (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not locate the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file to be deleted.

If you use a full or partial path for either file, see **Path Separators** on page III-398 for details on forming the path.

Flags

/I — Interactive mode displays the Open File dialog even if *fileNameStr* is specified and the file exists.

/M=*messageStr* — Specifies the prompt message for the Open File dialog.

/P=*pathName* — Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.

/Z[=*z*] — Prevents procedure execution from aborting if it attempts to delete a file that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

- /Z=0: Same as no /Z.
- /Z=1: Deletes a file only if it exists. /Z alone has the same effect as /Z=1.
- /Z=2: Deletes a file if it exists or displays a dialog if it does not exist.

Variables

The DeleteFile operation returns information in the following variables:

V_flag Set to zero if the file was deleted, to -1 if the user cancelled the Open File dialog, and to some nonzero value if an error occurred, such as the specified file does not exist.

S_path Stores the full path to the file that was deleted. If an error occurred or if the user cancelled, it is set to an empty string.

See Also

DeleteFolder, **MoveFile**, **CopyFile**, **NewPath**, and **Symbolic Paths** on page II-34.

DeleteFolder

DeleteFolder [***flags***] [***folderNameStr***]

The DeleteFolder operation deletes a disk folder and all of its contents.

Warning: *The DeleteFolder command destroys data!* The deleted folder and the contents are not moved to the Trash or Recycle Bin.

DeleteFolder will delete a folder only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category. For further details see **Misc Settings** on page III-414.

If permission is denied, the folder will not be deleted and V_Flag will return 1088 (Command is disabled) or 1276 (You denied permission to delete a folder). Command execution will cease unless the /Z flag is specified.

Parameters

folderNameStr can be a full path to the folder to be deleted, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a folder within the folder associated with *pathName*.

If Igor can not determine the location of the folder from *folderNameStr* and *pathName*, it displays a Select Folder dialog allowing you to specify the folder to be deleted.

If /P=*pathName* is given, but *folderNameStr* is not, then the folder associated with *pathName* is deleted.

If you use a full or partial path for either folder, see **Path Separators** on page III-398 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

Flags

/I Interactive mode displays a Select Folder dialog even if *folderNameStr* is specified and the folder exists.

/M=*messageStr* Specifies the prompt message for the Select Folder dialog.

/P=*pathName* Specifies the folder to look in for the folder. *pathName* is the name of an existing symbolic path.

/Z[=*z*] Prevents procedure execution from aborting if it attempts to delete a folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

- /Z=0: Same as no /Z.
- /Z=1: Deletes a folder only if it exists. /Z alone has the same effect as /Z=1.
- /Z=2: Deletes a folder if it exists or displays a dialog if it does not exist.

Variables

The DeleteFolder operation returns information in the following variables:

V_flag Set to zero if the folder was deleted, to -1 if the user cancelled the Select Folder dialog, and to some nonzero value if an error occurred, such as the specified folder does not exist.

S_path Stores the full path to the folder that was deleted, with a trailing semicolon. If an error occurred or if the user cancelled, it is set to an empty string.

Details

You can use only /P=*pathName* (without *folderNameStr*) to specify the source folder to be deleted.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

See Also

The **DeleteFile**, **MoveFolder**, **CopyFolder**, **NewPath**, and **IndexedDir** operations. **Symbolic Paths** on page II-34.

DeletePoints

DeletePoints [**/M=***dim*] ***startElement, numElements, waveName***
[**, *waveName***]…

The DeletePoints operation deletes *numElements* elements from the named waves starting from element *startElement*.

Flags

/M=*dim* *dim* specifies the dimension from which elements are to be deleted. Values are:

0: Rows.

1: Columns.

2: Layers.

3: Chunks.

If /M is omitted, DeletePoints deletes from the rows dimension.

Details

Removing all but one element from the highest dimension of a wave reduces the dimensionality of the wave by one.

A wave may have any number of points, including zero. Removing all elements from any dimension removes all points from the wave, leaving a 1D wave with zero points.

See Also

The **Redimension** operation.

deltax

deltax(*waveName*)

The deltax function returns the named wave's dx value. deltax works with 1D waves only.

Details

This is equal to the difference of the X value of point 1 minus the X value of point 0.

See Also

The **leftx** and **rightx** functions.

When working with multidimensional waves, use the **DimDelta** function.

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-83.

DFREF

DFREF *localName* [= *path* or *dfr*], [*localName1* [= *path* or *dfr*]]

DFREF is used to define a local data folder reference variable or input parameter in a user-defined function.

Requires Igor Pro 6.1 or later.

The syntax of the DFREF is:

```
DFREF localName [= path or dfr ][, localName1 [= path or dfr ]]...
```

where *dfr* stands for "data folder reference". The optional assignment part is used only in the body of a function, not in a parameter declaration.

Unlike the **WAVE** reference, a DFREF in the body without the assignment part does not do any lookup. It simply creates a variable whose value is null.

Examples

```
Function Test(dfr)
   DFREF dfr

   Variable dfrStatus = DataFolderRefStatus(dfr)
```

```
    if (dfrStatus == 0)
        Print "Invalid data folder reference"
        return -1
    endif

    if (dfrStatus & 2)            // Bit 1 set means free data folder
        Print "Data folder reference refers to a free data folder"
    endif

    if (dfrStatus == 1)
        Print "Data folder reference refers a global data folder"
        DFREF dfSav = GetDataFolderDFR()
        Print GetDataFolder(1)     // Print data folder path
        SetDataFolder dfSav
    endif

    Make/O dfr:jack=sin(x/8)      // Make a wave in the referenced data folder

    return 0
End
```

See Also

For information on programming with data folder references, see **Data Folder References** on page IV-61.

Differentiate

Differentiate [*type* ***flags***][***flags***] ***yWaveA*** [**/X = *xWaveA***]
[**/D = *destWaveA***][, ***yWaveB*** [**/X = *xWaveB***][**/D = *destWaveB***][, …]]

The Differentiate operation calculates the 1D numerical derivative of a wave.

Flags

/DIM=*d* Specifies the wave dimension along which to differentiate when *yWave* is multi-dimensional.

d=-1: Treats entire wave as 1D (default).

For *d*=0, 1, 2, 3, Differentiate operates along rows, columns, layers or chunks.

For example, for a 2D wave, /DIM=0 differentiates each row and /DIM=1 differentiates each column.

/EP=*e* Controls end point handling.

e=0: Replaces undefined points with an approximation (default).

e=1: Deletes the point(s).

/METH=*m* Sets the differentiation method.

m=0: Central difference (default).

m=1: Forward difference.

m=2: Backward difference.

/P Forces point scaling.

Type Flags (*used only in functions***)**

Differentiate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-58 and **WAVE Reference Type Flags** on page IV-58 for a complete list of type flags and further details.

Wave Parameters

Note: ***All*** wave parameters must follow *yWave* in the command. All wave parameter flags and type flags must appear immediately after the operation name.

/D=*destWave* Specifies the name of the wave to hold the differentiated data. It creates *destWave* if it does not already exist or overwrites it if it exists.

/X=*xWave* Specifies the name of the corresponding X wave.

Details

If the optional /D = *destWave* flag is omitted, then the wave is differentiated in place overwriting the original data.

When using a method that deletes points (/EP=1) with a multidimensional wave, deletion is not done if no dimension is specified.

When using an X wave, the X wave must match the Y wave data type (excluding the complex type flag) and it must be 1D with the number points matching the size of the dimension being differentiated. X waves are not used with integer source waves.

`Differentiate/METH=1/EP=1` is the inverse of `Integrate/METH=2`, but `Integrate/METH=2` is the inverse of `Differentiate/METH=1/EP=1` only if the original first data point is added to the output wave.

Differentiate applied to an XY pair of waves does not check the ordering of the X values and doesn't care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves first (see **Sort**).

See Also

The **Integrate** operation.

digamma

digamma(*x*)

The digamma function returns the digamma, or psi function of *x*. This is the logarithmic derivative of the gamma function:

$$\psi(z) \equiv \frac{\mathrm{d}}{\mathrm{d}z}\ln\Gamma(z) = \frac{\Gamma'(z)}{\Gamma(z)}.$$

In complex expressions, *x* is complex, and `digamma(x)` returns a complex value.

Limited testing indicates that the accuracy is approximately 1 part in 10^{16}, at least for moderately-sized values of *x*.

DimDelta

DimDelta(*waveName, dimNumber*)

The DimDelta function returns the scale factor delta of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks. If *dimNumber*=0 this is identical to `deltax(waveName)`.

See Also

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-83.

DimOffset

DimOffset(*waveName, dimNumber*)

The DimOffset function returns the scaling offset of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. If *dimNumber*=0 this is identical to `leftx(waveName)`.

See Also

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-83.

DimSize

DimSize(*waveName, dimNumber*)

The DimSize function returns the size of the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. For a 1D wave, `DimSize(waveName,0)` is identical to `numpnts(waveName)`.

Dir

Dir [*dataFolderSpec*]

The Dir operation returns a listing of all the objects in the specified data folder.

Parameters

If you omit *dataFolderSpec* then the current data folder is used.

If present, *dataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

Details

The format of the printed information is the same as the format used by the string function **DataFolderDir**. Igor programmers may find it more convenient to use **CountObjects** and **GetIndexedObjName**.

Usually it is easier to use the Data Browser (Data menu). However, **Dir** is useful when you want to copy a name into the command line or when you want to document the current state of the folder in the history.

See Also

Chapter II-8, **Data Folders**.

Display

Display [*flags*] [*waveName* [, *waveName*]…[**vs** *xwaveName*]]
[**as** *titleStr*]

The Display operation creates a new graph window or subwindow, and appends the named waves, if any. Waves are displayed as 1D traces.

By default, waves are plotted versus the left and bottom axes. Use the /L, /B, /R, and /T flags to plot the waves against other axes.

Parameters

Up to 100 *waveName*s may be specified, subject to the 400 character command limit. If no wave names are specified, a blank graph is created and the axis flags are ignored.

If you specify "vs *xwaveName*", the Y values of the named waves are plotted versus the Y values of *xwaveName*. If you don't specify "vs *xwaveName*", the Y values of each *waveName* are plotted versus its own X values.

If *xwaveName* is a text wave, the resulting plot is a category plot. Each element of *waveName* is plotted by default in bars mode (`ModifyGraph mode=5`) against a category labeled with the text of the corresponding element of *xwaveName*.

The Y waves for a category plot should have point scaling (see **Changing Dimension and Data Scaling** on page II-83); this is how category plots were intended to work. However, if all the Y waves have the same scaling, it will work correctly.

titleStr is a string expression containing the graph's title. If not specified, Igor will provide one which identifies the waves displayed in the graph.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-288.

You can provide a custom name for a trace by appending /TN=traceName to the waveName specification. This may be useful when displaying waves with the same name but from different data folders. See **User-defined Trace Names** on page IV-71 for more information. This feature was added in Igor Pro 6.20.

Flags

/B[=*axisName*] Plots X coordinates versus the standard or named bottom axis.

/FG=(*gLeft*, *gTop*, *gRight*, *gBottom*)
Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are `FL`, `FR`, `FT`, and `FB`, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use `*` to specify a default guide name.

Guides may override the numeric positioning set by /W.

/HIDE=*h* Hides (h = 1) or shows (h = 0, default) the window.

/HOST=*hcSpec*
: Embeds the new graph in the specified host window or subwindow *hcSpec*.

  When identifying a subwindow with *hcSpec*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

/I
: Specifies that /W coordinates are in inches.

/K=*k*
: Specifies window behavior when the user attempts to close it.

  k=0: Normal with dialog (default).

  k=1: Kills with no dialog.

  k=2: Disables killing.

  k=3: Hides the window.

  If you use /K=2 or /K=3, the only way to kill the window is via the DoWindow/K operation.

/L[=*axisName*]
: Plots Y coordinates versus the standard or named left axis.

/M
: Specifies that /W coordinates are in centimeters.

/N=*name*
: Requests that the created graph have this name, if it is not in use. If it is in use, then *name*0, *name*1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen graph name. Use `DoWindow/K name` to ensure that *name* is available.

/PG=(*gLeft*, *gTop*, *gRight*, *gBottom*)
: Specifies the inner plot rectangle of the graph subwindow inside its host window.

  The standard plot rectangle guide names are `PL`, `PR`, `PT`, and `PB`, for the left, right, top, and bottom plot rectangle guides, respectively, or user-defined guide names as defined by the host. Use `*` to specify a default guide name.

  Guides may override the numeric positioning set by /W.

/R[=*axisName*]
: Plots Y coordinates versus the standard or named right axis.

/T[=*axisName*]
: Plots Y coordinates versus the standard or named top axis.

/W=(*left*,*top*,*right*,*bottom*)
: Gives the graph a specific location and size on the screen. Coordinates for /W are in points unless /I or /M are specified before /W.

  When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings:

  1) When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.
  2) When any value is greater than 1, coordinates are taken to be fixed locations measured in points relative to the top left corner of the host frame.

  When the subwindow position is fully specified using guides (using the /HOST, /FG, or /PG flags), the /W flag may still be used although it is not needed.

Details

If /N is not used, Display automatically assigns to the graph a name of the form "Graph*n*", where *n* is some integer. In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the graph from a procedure. Use the **RenameWindow** operation to rename the graph.

Examples

To make a contour plot, use:

```
Display; AppendMatrixContour waveName
```

or

```
Display; AppendXYZContour waveName
```

To display an image, use:

```
Display; AppendImage waveName
```

or

```
NewImage waveName
```

See Also

The **AppendToGraph** operation.

The operations **AppendImage**, **AppendMatrixContour**, **AppendXYZContour**, and **NewImage**. For more information on Category Plots, see Chapter II-13, **Category Plots**.

The operations **ModifyGraph**, **ModifyContour**, and **ModifyImage** for changing the characteristics of graphs.

The **DoWindow** operation for changing aspects of the graph window.

DisplayHelpTopic

DisplayHelpTopic [**/K=*k* /Z**] ***TopicString***

The DisplayHelpTopic operation displays a help topic as if a help link had been clicked in an Igor help file.

Parameters

TopicString is string expression containing the topic. It may be in one of three forms: <topic name>, <subtopic name>, <topic name>[<subtopic name>]. These forms are illustrated by the examples.

Make sure that your topic string is specific to minimize the likelihood that Igor will find the topic in a help file other than the one you intended. To avoid this problem, it is best to use the <topic name>[<subtopic name>] form if possible.

Flags

/K=*k* *k*=0: Leaves the help file open indefinitely (default). Use this if the help topic may be of interest in any experiment.

k=1: If the found topic is in a closed help file, the help file closes with the current experiment. Use this if the help topic is tightly associated with the current experiment.

/Z Ignore errors. If /Z is used, DisplayHelpTopic sets V_flag to 0 if the help topic was found or to a nonzero error code if it was not found. V_flag is set only when /Z is used.

Details

DisplayHelpTopic first searches for the specified topic in the open help files. If the topic is not found, it then searches all help files in the Igor Pro folder and subfolders.

If the topic is still not found, it then searches all help files in the current experiment's home folder, but not in subfolders. This puts a help file that is specific to a particular experiment in the experiment's home folder.

If the topic is still not found and if DisplayHelpTopic was called from a procedure and if the procedure resides in a stand-alone file on disk (i.e., it is not in the built-in procedure window or in a packed procedure file), Igor then searches all help files in the procedure file's folder, but not in subfolders. This puts a help file that is specific to a particular set of procedures in the same folder as the procedure file.

If Igor finds the topic, it displays it. If Igor can not find the topic, it displays an error message, unless /Z is used.

Examples

```
// This example uses the topic only.
DisplayHelpTopic "Waves"

// This example uses the subtopic only.
DisplayHelpTopic "Waveform Arithmetic and Assignment"

// This example uses the topic[subtopic] form.
DisplayHelpTopic "Waves[Waveform Arithmetic and Assignment]"
```

See Also

Chapter II-1, **Getting Help** for information about Igor help files and formats.

DisplayProcedure

DisplayProcedure [**/B=*winTitleOrName* /W=*procWinTitle***] [***functionOrMacroNameStr***]

The DisplayProcedure operation displays the named function or macro by bringing the procedure window it is defined in to the front with the function or macro highlighted.

Parameters

functionOrMacroNameStr is string expression containing the function or macro name. If omitted, you must use /W. *functionOrMacroNameStr* may also contain independent module and/or module name prefixes to display static functions.

Flags

/B=*winTitleOrName* Brings up the procedure window just behind the window with this name or title.

/W=*procWinTitle* Searches in the procedure window with this title. If omitted, it searches all open (nonindependent module) procedure windows.

Details

If a procedure window has syntax errors that prevent Igor from determining where functions and macros start and end, then DisplayProcedure may not be able to locate the procedure.

winTitleOrName is not a string; it is a name. To position the found procedure window behind a window whose title has a space in the name, use the $ operator as in the second example, below.

If *winTitleOrName* does not match any window, then the found procedure window is placed behind the top target window.

procWinTitle is also a name. Use `/W=$"New Polar Graph.ipf"` to search for the function or macro in only that procedure file.

Advanced Details

If `SetIgorOption IndependentModuleDev=1`, *procWinTitle* can also be a title followed by a space and, in brackets, an independent module name. In such cases searches for the function or macro are in the specified procedure window and independent module. (See **Independent Modules** on page IV-214 for independent module details.)

For example, if any procedure file contains these statements:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

The command

```
DisplayProcedure/W=$"Axis Utilities.ipf [myIM]" "HVAxisList"
```

opens the procedure window that contains the `HVAxisList` function, which is in the Axis Utilities.ipf file and the independent module `myIM`. The command uses the `$""` syntax because space and bracket characters interfere with command parsing.

Similarly, if `SetIgorOption IndependentModuleDev=1` then *functionOrMacroNameStr* may also contain an independent module prefix followed by the # character. The preceding command can be rewritten as:

```
DisplayProcedure/W=$"Axis Utilities.ipf" "myIM#HVAxisList"
```

or more simply

```
DisplayProcedure "myIM#HVAxisList"
```

You can use the same syntax to display a static function in a non-independent module procedure file using a module name instead of (or in addition to) the independent module name.s

procWinTitle can also be just an independent module name in brackets to retrieve the text from *any* procedure window that belongs to named independent module:

```
DisplayProcedure/W=$"[myIM]" "HVAxisList"
```

Examples

```
DisplayProcedure "Graph0"
DisplayProcedure/B=$"Strings as Lists.ipf" "MyOwnUserFunction"
DisplayProcedure/W=Procedure         // Shows the main Procedure window
DisplayProcedure/W=$"Strings as Lists.ipf"
```

```
DisplayProcedure "moduleName#myStaticFunctionName"
SetIgorOption IndependentModuleDev=1
```

```
DisplayProcedure "WMGP#GizmoBoxAxes#DrawAxis"
```

See Also

Independent Modules on page IV-214.

MacroList, **FunctionList**, and **ProcedureText**, **HideProcedures**, **DoWindow**.

do-while

```
do
   <loop body>
while(<expression>)
```

A do-while loop executes *loop body* until *expression* evaluates as FALSE (zero) or until a break statement is executed.

See Also

Do-While Loop on page IV-36 and **break** for more usage details.

DoAlert

```
DoAlert [/T=titleStr] alertType, promptStr
```

The DoAlert operation displays an alert dialog and waits for user to click button.

Parameters

alertType= 0: Dialog with an OK button.
1: Dialog with Yes button and No buttons.
2: Dialog with Yes, No, and Cancel buttons.

promptStr text that is displayed in the alert dialog.

Flags

/T=*titleStr* Changes the title of the dialog window from the default title.

Details

DoAlert sets the variable V_flag as follows:

V_flag= 1: Yes clicked.
2: No clicked.
3: Cancel clicked.

See Also

The **Abort** operation.

DoIgorMenu

```
DoIgorMenu [/C] MenuNameStr, MenuItemStr
```

The DoIgorMenu operation allows an Igor programmer to invoke Igor's built-in menu items. This is useful for bringing up Igor's built-in dialogs under program control.

Parameters

MenuNameStr The name of an Igor menu, like "File", "Graph", or "Load Waves".

MenuItemStr The text of an Igor menu item, like "Copy" (in the Edit menu) or "New Graph" (in the Windows menu).

Flags

/C Just Checking. The menu item is not invoked, but V_flag is set to 1 if the item was enabled or to 0 if it was not enabled.

Details

All menu names and menu item text are in English to ensure that code developed for a localized version of Igor Pro will run on all versions. Note that no trailing "…" is used in *MenuItemStr*.

V_flag is set to 1 if the corresponding menu item was enabled, which usually means the menu item was successfully selected. Otherwise V_flag is 0. V_flag does not reflect the success or failure of the resulting dialog, if any.

If the menu item selection displays a dialog that generates a command, clicking the Do It button executes the command immediately without using the command line as if Execute/Z operation had been used. Clicking the To Cmd Line button appends the command to the command line rather than inserting the command at the front.

The DoIgorMenu operation will not attempt to select a menu during curve fitting. Doubtless there are other times during which using DoIgorMenu would be unwise.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the *MenuItemStr* parameter. Use "Save Window", "Save Window As", "Save Window Copy", "Adopt Window", and "Revert Window" instead of "Save Notebook" or "Save Procedure", etc. Use "Page Setup" instead of "Page Setup For All Graphs", etc. Use "Print" instead of "Print Graph", etc.

See Also

The **SetIgorMenuMode** and **Execute** operations.

DoPrompt

DoPrompt [**/HELP=*helpStr***] ***dialogTitleStr, variable*** [**, *variable***]…

The DoPrompt command in a function invokes the simple input dialog. A DoPrompt specifies the title for the simple input dialog and which input variables are to be included in the dialog.

Flags

/HELP=*helpStr* Sets the help topic or help text that appears when the dialog's Help button is pressed.

helpStr can be a help topic and subtopic such as is used by `DisplayHelpTopic/K=1` *`helpStr`*, or it can be text (255 characters max) that is displayed in a subdialog just as if `DoAlert 0,` *`helpStr`* had been called, or *helpStr* can be `""` to remove the Help button.

Parameters

variable is the name of a dialog input variable, which can be real or complex numeric local variable or local string variable, defined by a Prompt statement. You can specify as many as 10 variables.

dialogTitleStr is a string or string expression containing the text for the title of the simple input dialog.

Details

Prompt statements are required to define what variables are to be used and the text for any string expression to accompany or describe the input variable in the dialog. When a DoPrompt variable is missing a Prompt statement, you will get a compilation error. Pop-up string data can not be continued across multiple lines as can be done using Prompt in macros. See **Prompt** for further usage details.

Prompt statements for the input variables used by DoPrompt must come before the DoPrompt statement itself, otherwise, they may be used anywhere within the body of a function. The variables are not required to be input parameters for the function (as is the case for Prompt in macros) and they may be declared within the function body. DoPrompt can accept as many as 10 variables.

Functions can use multiple DoPrompt statements, and Prompt statements can be reused or redefined.

When the user clicks the Cancel button, any new input parameter values are not stored in the variables.

DoPrompt sets the variable V_flag as follows:

`V_flag=` 0: Continue button clicked.

1: Cancel button clicked.

See Also

The Simple Input Dialog on page IV-122, the **Prompt** keyword, and **DisplayHelpTopic**.

DoUpdate

DoUpdate [**/E=*e* /W=*targWin* /SPIN=*ticks***]

The DoUpdate operation updates windows and dependent objects.

Flags

/E=*e* Used with /W, /E=1 marks window as a progress window that can accept mouse events while user code is executing. Currently, only control panel windows can be used as a progress window.

/W=*targWin* Updates only the specified window. Does not update dependencies or do any other updating. V_Flag is set to the truth the window exists. Currently, only graph and panel windows honor the /W flag.

/SPIN=*ticks* Sets the delay between the start of a control procedure and the spinning beachball. *ticks* is the delay in ticks (60th of a second.) Unless used with the /W flag, /SPIN just sets the delay and an update is not done.

Details

Call DoUpdate from an Igor procedure to force Igor to update any objects that need updating. Igor updates any graphs, tables or page layouts that need to be updated and also any objects (string variables, numeric variables, waves, controls) that depend on other objects that have changed since the last update.

Igor performs updates automatically when:

- No user-procedure is running.
- An interpreted procedure (Macro, Proc, Window type procedures) is running and PauseUpdate or DelayUpdate is not in effect.

An automatic DoUpdate is not done while a user-defined function is running. You can call DoUpdate from a user-defined function to force an update.

See Also

The **DelayUpdate**, **PauseUpdate**, and **ResumeUpdate** operations, **Progress Windows** on page IV-134.

DoWindow

DoWindow [***flags***] [***windowName***]

The DoWindow operation controls various window parameters and aspects. There are additional forms for DoWindow when the /S or /T flags are used; see the following DoWindow entries.

Parameters

windowName is the name of a graph, table, page layout, notebook, panel or XOP target window.

A window's name is *not* the same as its title. The title is shown in the window's title bar. The name is used to manipulate the window from Igor commands. You can check both the name and the title using the Window Control dialog (in the Arrange submenu of the Window menu).

Flags

/B[=*bname*] Moves the specified window to the back (to the bottom of desktop) or behind window *bname*.

/C Changes the name of the target window to the specified name. The specified name must not be used for any other object except that it can be the name of an existing window macro.

/C/N Changes the target window name and creates a new window macro for it. However, /N does nothing if a macro or function is running. /N is not applicable to notebooks.

/D Deletes the file associated with window, if any (for notebooks only).

/F Brings the window with the given name to the front (top of desktop).

/H Specifies the command/history window as the target of the operation. When using /H, *windowName* must not be specified and only the /B and /HIDE flags are honored.

Use /H to bring the command window to the front (top of desktop).

Use /H/B to send the history/command window to the bottom of the desktop.

Use /H/HIDE to hide or show the command window.

/HIDE=*h* Sets hidden state of a window.

h=0: Visible.

h=1: Hidden.

h=?: Sets the variable V_flag as follows:

0: The window does not exist.

1: The window is visible.

2: The window is hidden.

You can also read the hidden state using **GetWindow** and set it using **SetWindow**.

/K Kills the window with the given name.

/N Creates a new window macro for the window with the given name. However, /N does nothing if a macro or function is running. /N is not applicable to notebooks.

/R Replaces (updates) the window macro for the named window or creates it if it does not yet exist. However, /R does nothing if a macro or function is running. /R is not applicable to notebooks.

/R/K — Replaces (updates) the window macro for the named window or creates it if it does not yet exist and then kills the window. However, /R does nothing if a macro or function is running. /R is not applicable to notebooks.

/W=*targWin* — Designates *targWin* as the target window; it also requires that you specify *windowName*. Use this mainly with floating panels, which are always on top. You can use a subwindow specification of an external subwindow only with the /T flag or without any flags.

Details

DoWindow sets the variable V_flag to 1 if there was a window with the specified name after DoWindow executed, to 0 if there was no such window, or to 2 if the window is hidden.

Call DoWindow with no flags to check if a window exists.

When used with the /N flag, *windowName* must not conflict with the name of any other object. When used with the /C flag, *windowName* must not conflict with the name of any other object except that it can be the name of an existing window macro.

As of Igor Pro 3.13, the /R and /N flags do nothing when executed while a macro or function is running. This is necessary because changing procedures while they are executing causes unpredictable and undesirable results. However you can use the Execute/P operation to cause the DoWindow command to be executed after procedures are finished running. For example:

```
Function SaveWindowMacro(windowName)
   String windowName                    // "" for top graph or table
   if (strlen(windowName) == 0)
      windowName = WinName(0, 3)        // Name of top graph or table
   endif
   String cmd
   sprintf cmd, "DoWindow/R %s", windowName
   Execute/P cmd
End
```

You can use the /D flag in conjunction with the /K flag to kill a notebook window and delete its associated file, if any. /D has no effect on any other type of window and has no effect if the /K flag is not present.

Examples

```
DoWindow Graph0            // Set V_flag to 1 if Graph0 window exists.
DoWindow/F Graph0          // Make Graph0 the top/target window.
DoWindow/C MyGraph         // Target window (Graph0) renamed MyGraph.
DoWindow/K Panel0          // Kill the Panel0 window.
DoWindow/H/B               // Put the history/command window in back.
DoWindow/D/K Notebook2     // Kill Notebook2, delete its file.
```

See Also

The **RenameWindow** operation for renaming windows or subwindows.

The **IgorInfo** function, the **HideProcedures** operation, and the following DoWindow sections.

DoWindow/T

DoWindow /T *windowName, windowTitleStr*

The DoWindow/T operation sets the window title for the named window to the specified title.

Details

The title is shown in the window's title bar, and listed in the appropriate Windows submenu. The window *name* is still used to manipulate the window, so, for example, the window name (if *windowName* is a graph or table) is listed in the New Layout dialog; not the title.

You can check both the name and the title using the Window Control dialog (in the Control submenu of the Windows menu).

windowName is the name of the window or a special keyword, kwTopWin or kwFrame.

If *windowName* is kwTopWin, DoWindow retitles the top target window.

If *windowName* is kwFrame, DoWindow retitles the "frame" or "application" window that Igor has only under Windows. This is the window that contains Igor's menus and status bar. On Macintosh, kwFrame is allowed, but the command does nothing.

The Window Control dialog does not support kwFrame. The frame title persists until Igor quits or until it is restored as shown in the example. Setting *windowTitleStr* to "" will restore the normal frame title.

Examples

```
DoWindow/T MyGraph, "My Really Neat Graph"
DoWindow/T kwFrame, "My Igor-based Application"
DoWindow/T kwFrame, ""           // restore normal frame title
```

DoWindow/S

DoWindow /N/S=*styleMacroName windowName*

DoWindow /R/S=*styleMacroName windowName*

The DoWindow/S operation creates a new "style macro" for the named window, using the specified style macro name. Does not create or replace the window macro for the specified window.

Flags

/N/S=*styleMacroName* Creates a new style macro with the given name based on the named window.

/R/S=*styleMacroName* Creates or replaces the style macro with the given name based on the named window.

Details

The /R or /N flag must appear before the /S flag.

If the /S flag is present, the DoWindow operations does *not* create or replace the window macro for the specified window.

As of Igor Pro 3.13, the /R and /N flags do nothing when executed while a macro or function is running. This is necessary because changing procedures while they are executing causes unpredictable and undesirable results.

DoXOPIdle

DoXOPIdle

The DoXOPIdle operation sends an IDLE event to all open XOPs. This operation is very specialized. Generally, only the author of an XOP will need to use this operation.

Details

Some XOPs (External OPeration code modules) require IDLE events to perform certain tasks. For example, the SoundInput XOP on the Macintosh transfers sound data from an interrupt buffer to an Igor Named FIFO only during an IDLE event.

Igor does not automatically send IDLE events to XOPs while an Igor program is running. You can call DoXOPIdle from a user-defined program to force Igor to send the event.

DrawAction

DrawAction [**/L=*layerName*/W=*winName***] ***keyword* = *value*** [**, *keyword* = *value*** …]

The DrawAction operation deletes, inserts, and reads back a named drawing object group or the entire draw layer.

Parameters

DrawAction accepts multiple *keyword* = *value* parameters on one line.

beginInsert [=*index*] Inserts draw commands before or at *index* position or at position specified by getgroup or delete parameters; position otherwise is zero.

commands [=*start*,*stop*] Stores commands in S_recreation for draw objects between *start* and *stop* index values, range defined by getgroup, or entire layer otherwise.

delete [=*start*,*stop*] Deletes draw objects between *start* and *stop* index values, range defined by getgroup, or entire layer otherwise.

extractOutline [=*start*,*stop*] Stores polygon outline between *start* and *stop* index values, range defined by getgroup, or entire layer otherwise. Waves W_PolyX and W_PolyY contain coordinates with NaN separators. V_npnts contains the number of objects. Coordinates are for the first object encountered.

endInsert Terminates insert mode.

getgroup=*name* Stores first and last index of named group in V_startPos and V_endPos. Use `_all_` to specify the entire layer. Sets V_flag to truth group exists.

Flags

/L=*layerName* Specifies the drawing layer on which to act. *layerName* is one of the drawing layers as specified in **SetDrawLayer**.

/W=*winName* Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

Commands stored in S_recreation are the same as those that would be generated for the range of objects in the recreation macro for the window but also have comment lines preceding each object of the form:

```
// ;ITEMNO:n;
```

where *n* is the item number of the draw object.

Examples

Create a drawing with a named group:

```
NewPanel /W=(455,124,936,413)
SetDrawEnv fillfgc= (65535,0,0)
DrawRect 58,45,132,103
SetDrawEnv gstart,gname= fred
SetDrawEnv fillfgc= (65535,43690,0)
DrawRect 79,62,154,120
SetDrawEnv arrow= 1
DrawLine 139,70,219,70
SetDrawEnv gstop
SetDrawEnv fillfgc= (0,65535,65535)
DrawRect 95,77,175,138
SetDrawEnv fillfgc= (0,0,65535)
DrawRect 111,91,191,156
```

Get and print commands for the “fred” group:

```
DrawAction getgroup=fred,commands
Print S_recreation
```

prints:

```
// ;ITEMNO:3;
SetDrawEnv gstart,gname= fred
// ;ITEMNO:4;
SetDrawEnv fillfgc= (65535,43690,0)
// ;ITEMNO:5;
DrawRect 79,62,154,120
// ;ITEMNO:6;
SetDrawEnv arrow= 1
// ;ITEMNO:7;
DrawLine 139,70,219,70
// ;ITEMNO:8;
SetDrawEnv gstop
```

Replace group fred (the orange rectangle and the arrow) with a different object. First delete the group and enter insert mode:

```
DrawAction getgroup=fred, delete, begininsert
```

Next draw the replacement:

```
SetDrawEnv gstart,gname= fred
SetDrawEnv fillfgc= (65535,65535,0)
DrawOval 82,62,161,123
SetDrawEnv gstop
```

Lastly exit insert mode:

```
DrawAction endinsert
```

See Also

The **SetDrawEnv** operation and Chapter III-3, **Drawing**.

DrawArc

DrawArc [**/W=*winName*/X/Y**] ***xOrg*, *yOrg*, *arcRadius*, *startAngle*, *stopAngle***

The DrawArc operation draws a circular counterclockwise arc with center at *xOrg* and *yOrg*.

Parameters

(*xOrg*, *yOrg*) defines the center point for the arc in the currently active coordinate system.

Angles are measured in degrees increasing in a counterclockwise direction. The *startAngle* specifies the starting angle for the arc and *stopAngle* specifies the end. If *stopAngle* is equal to *startAngle*, 360° is added to *stopAngle*. Thus, a circle can be drawn using *startAngle* = *stopAngle*.

The *arcRadius* is the radial distance measured in points from (*xOrg*, *yOrg*).

Flags

/W=*winName*	Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.
/X	Measures *arcRadius* using the current X-coordinate system. If /Y is also used, the arc may be elliptical.
/Y	Measures *arcRadius* using the current Y-coordinate system. If /X is also used, the arc may be elliptical.

Details

Arcs honor the current dash pattern and arrowhead setting in the same way as polygons and Beziers. In fact, arcs are implemented using Bezier curves.

Normally, you would create arcs programmatically. If you need to sketch an arc-like object, you should probably use a Bezier curve because it is more flexible and easier to adjust. However, there is one handy feature of arcs that make them useful for manual drawing: the origin can be in any of the supported coordinate systems and the radius is in points.

To draw an arc interactively, see **Arcs and Circles** on page III-72 for instructions.

See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv** and **SetDrawLayer** operations.

The **DrawBezier**, **DrawOval** and **DrawAction** operations.

DrawBezier

DrawBezier [**/W=*winName* /ABS**] ***xOrg*, *yOrg*, *hScaling*, *vScaling*, {x_0,y_0,x_1,y_1 …}**

DrawBezier [**/W=*winName* /ABS**] ***xOrg*, *yOrg*, *hScaling*, *vScaling*, *xWaveName*, *yWaveName***

DrawBezier/A [**/W=*winName***] {x_n, y_n, x_{n+1}, y_{n+1} …}

The DrawBezier operation draws a Bezier curve with first point of the curve positioned at *xOrg* and *yOrg*.

Parameters

(*xOrg*, *yOrg*) defines the starting point for the Bezier curve in the currently active coordinate system.

hScaling and *vScaling* set the horizontal and vertical scale factors about the origin, with 1 meaning 100%.

The *xWaveName*, *yWaveName* version of DrawBezier gets data from the named X and Y waves. This connection is maintained so that any changes to either wave will result in updates to the Bezier curve.

To use the version of DrawBezier that takes a literal list of vertices, you place as many vertices as you like on the first line and then use as many /A versions as necessary to define all the vertices.

Flags

/A	Appends the given vertices to the currently open Bezier (freshly drawn or current selection).
/ABS	Suppresses the default subtraction of the first point from the rest of the data.

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

Data waves defining Bezier curves must have 1+3**n* data points. Every third data point is an anchor point and lies on the curve; intervening points are control points that define the direction of the curve relative to the adjacent anchor point.

Normally, you should create and edit a Bezier curve using drawing tools, and not calculate values. See **Polygon Tool** on page III-73 for instructions.

As of Igor Pro 5.02, you can specify the /ABS flag to suppress the default subtraction of the first point. Also, you can now insert NaN values to break a bezier into pieces.

To change just the origin and scale without respecifying the data use:

```
DrawBezier xOrg, yOrg, hScaling, vScaling,{}
```

To delete an anchor point, press Option (*Macintosh*) or Alt (*Windows*) and then click on the anchor. To insert a new anchor, click on the curve between anchor points.

Example

Create a half circle approximation from three anchor points starting at the 12 o'clock position, with an anchor at the 3 o'clock position, and the last at the 6 o'clock position using explicit values:

```
// Set plot relative coords, 0-1, no fill
SetDrawEnv xcoord=prel, ycoord=prel, fillpat= 0, save

Variable len= 0.275       // control point length = 0.55 * radius for a circle
// Starting anchor point has only a trailing control point
Variable anchor0x= 0.5, anchor0y=1          // starting point at 6 o'clock
Variable t0x= 0.5+len, t0y= 1               // trailing control point

// second anchor point has both leading and trailing control points
Variable l1x=1, l1y = 0.5+len               // leading control point
Variable anchor1x= 1, anchor1y= 0.5         // 3 o'clock anchor
Variable t1x=1, t1y = 0.5-len               // trailing control point

// Last (3rd) anchor point has only a leading control point
Variable l2x=0.5+len, l2y = 0               // leading control point
Variable anchor2x= 0.5, anchor2y= 0         // 6 o'clock

// One command per anchor for clarity
DrawBezier anchor0x, anchor0y, 1,1, {anchor0x, anchor0y, t0x, t0y}
DrawBezier/A {l1x, l1y, anchor1x, anchor1y, t1x, t1y}
DrawBezier/A {l2x, l2y, anchor2x, anchor2y}
```

To draw using waves:

```
Make/O bezierX= {anchor0x, t0x, l1x, anchor1x, t1x, l2x, anchor2x }
Make/O bezierY= {anchor0y, t0y, l1y, anchor1y, t1y, l2y, anchor2y }
DrawBezier anchor0x, anchor0y, 1,1, bezierX, bezierY
```

The **DrawArc**, **DrawPoly** and **DrawAction** operations.

DrawLine

DrawLine [**/W=*winName***] x_0, y_0, x_1, y_1

The DrawLine operation draws a line in the target graph, layout or control panel from (*x0*,*y0*) to (*x1*,*y1*).

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The coordinate system as well as the line's thickness, color, dash pattern and other properties are determined by the current drawing environment. The line is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

DrawOval

DrawOval [**/W=*winName***] ***left, top, right, bottom***

The DrawOval operation draws an oval in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right,* and *bottom*.

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The coordinate system as well as the oval's thickness, color, dash pattern and other properties are determined by the current drawing environment (note that you cannot draw dashed ovals). The oval is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

DrawPICT

DrawPICT [**/W=*winName***][**/RABS**] ***left, top, hScaling, vScaling, pictName***

The DrawPICT operation draws the named picture in the target graph, layout or control panel. The *left* and *top* parameters set the position of the top/left corner of the picture. *hScaling* and *vScaling* set the horizontal and vertical scale factors with 1 meaning 100%.

Flags

/RABS Draws the named picture using absolute scaling. In this mode, it draws the picture in the rectangle defined by *left* and *top* for point (x0,y0), and by *hScaling* and *vScaling* for point (x1,y1), respectively.

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The coordinate system for the left and top parameters is determined by the current drawing environment. The PICT is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

DrawPoly

DrawPoly [**/W=*winName* /ABS**] ***xorg, yorg, hScaling, vScaling, xWaveName, yWaveName***
DrawPoly [**/W=*winName* /ABS**] ***xorg, yorg, hScaling, vScaling,*** $\{x_0,y_0,x_1,y_1 \ldots\}$
DrawPoly/A [**/W=*winName***] $\{x_n, y_n, x_{n+1}, y_{n+1} \ldots\}$

The DrawPoly operation draws a polygon in the target graph, layout or control panel.

Parameters

(*xorg*, *yorg*) defines the starting point for the polygon in the currently active coordinate system.

hScaling and *vScaling* set the horizontal and vertical scale factors, with 1 meaning 100%.

The *xWaveName*, *yWaveName* version of DrawPoly gets data from those X and Y waves. This connection is maintained so that changes to either wave will update the polygon.

The DrawPoly operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

To use the version of DrawPoly that takes a literal list of vertices, you place as many vertices as you like on the first line and then use as many /A versions as necessary to define all the vertices.

Flags

/A	Appends the given vertices to the currently open polygon (freshly drawn or current selection).
/ABS	Suppresses the default subtraction of the first point from the rest of the data.
/W=*winName*	Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

Because *xorg* and *yorg* define the location of the starting vertex of the poly, adding or subtracting a constant from the vertices will have no effect. The first XY pair in the {*x0*, *y0*, *x1*, *y1*,…} vertex list will appear at (*xorg*,*yorg*) *regardless* of the value of *x0* and *y0*. *x0* and *y0* merely serve to set a reference point for the list of vertices. Subsequent vertices are relative to (*x0*,*y0*).

To keep your mental health intact, we recommend that you specify (*x0*,*y0*) as (0,0) so that all the following vertices are offsets from that origin. Then (*xorg*,*yorg*) sets the position of the polygon and all of the vertices in the list are relative to that origin.

An alternate method is to use the same values for (*x0*,*y0*) as for (*xorg*,*yorg*) if you consider the vertices to be "absolute" coordinates.

As of Igor Pro 5.02, you can specify the /ABS flag to suppress the subtraction of the first point. Also, you can now insert NaN values to break a polygon into pieces.

To change just the origin and scale of the currently open polygon — without having to respecify the data — use:

```
DrawPoly xorg, yorg, hScaling, vScaling,{}
```

The coordinate system as well as the polygon's thickness, color, dash pattern and other properties are determined by the current drawing environment. The polygon is drawn in the current draw layer for the window, as determined by SetDrawLayer.

Examples

Here are some commands to draw some small triangles using absolute drawing coordinates (see **SetDrawEnv**).

```
Display             // make a new empty graph
//Draw one triangle, starting at 50,50 at 100% scaling
SetDrawEnv xcoord= abs,ycoord= abs
DrawPoly 50,50,1,1, {0,0,10,10,-10,10,0,0}
//Draw second triangle below and to the right, same size and shape
SetDrawEnv xcoord= abs,ycoord= abs
DrawPoly 100,100,1,1, {0,0,10,10,-10,10,0,0}
```

DrawRect

DrawRect [**/W=*winName***] ***left, top, right, bottom***

The DrawRect operation draws a rectangle in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right*, and *bottom*.

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The coordinate system as well as the rectangle's thickness, color, dash pattern and other properties are determined by the current drawing environment. The rectangle is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

DrawRRect

DrawRRect [**/W=*winName***] ***left, top, right, bottom***

The DrawRRect operation draws a rounded rectangle in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right*, and *bottom*.

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The coordinate system as well as the rectangle's rounding, thickness, color, dash pattern and other properties are determined by the current drawing environment. The rounded rectangle is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

DrawText

DrawText [**/W=*winName***] ***x_0, y_0, textStr***

The DrawText operation draws the specified text in the target graph, layout or control panel. The position of the text is defined by (*x0*, *y0*) along with the current environment settings of textxjust, textyjust and textrot parameters of **SetDrawEnv**.

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The coordinate system as well as the text's font, size, style and other properties are determined by the current drawing environment. The text is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

Chapter III-3, **Drawing**.

The **SetDrawEnv**, **SetDrawLayer** and **DrawAction** operations.

DSPDetrend

DSPDetrend [***flags***] ***srcWave***

The DSPDetrend operation removes from *srcWave* a trend defined by the best fit of the specified function to the data in *srcWave*.

Flags

/F= *function*	*function* is the name of a built-in curve fitting function: gauss, lor, exp, dblexp, sin, line, poly (requires /P flag), hillEquation, sigmoid, power, lognormal, poly2d (requires /P flag), gauss2d. If *function* is unspecified, the defaults are line if *srcWave* is 1D or poly2d if *srcWave* is 2D.
/M=*maskWave*	Detrending will only affect points that are nonzero in *maskWave*. Note that *maskWave* must have the same dimensionality as *srcWave*.
/P=*polyOrder*	Specifies polynomial order for poly or poly2d functions (see **CurveFit** for details). By default *polyOrder* =3 for the 1D case and *polyOrder* =1 for the 2D case.
/Q	Quiet mode; no error reporting.

Details

DSPDetrend sets V_flag to zero when the operation succeeds, otherwise it will be set to -1 or will contain an error code from the curve fitting routines. Results are saved in the wave W_Detrend (for 1D input) or M_Detrend (for 2D input) in the current data folder. If a wave by that name already exists in the current data folder it will be overwritten.

See Also

CurveFit for more information about V_FitQuitReason and the built-in fitting functions.

DSPPeriodogram

DSPPeriodogram [***flags***] ***srcWave*** [***srcWave2***]

The DSPPeriodogram operation calculates the periodogram, cross-spectral density or the degree of coherence of the input waves. The result of the operation is stored in the wave W_Periodogram in the current data folder.

To compute the cross-spectral density or the degree of coherence, you need to specify the second wave using the optional *srcWave2* parameter. In this case, W_Periodogram will be complex and the /dB and /dBR flags do not apply.

Flags

/dB	Expresses results in dB using the maximum value as reference.
/dBR=*ref*	Express the results in dB using the specified *ref* value.
/COHR	Computes the degree of coherence. This flag applies when the input consists of two waves.
/DLSG	When computing the periodogram, cross-spectral density or the degree of coherence using multiple segments the operation by default pads the last segment with zeros as necessary. If you specify this flag, an incomplete last segment is dropped and not included in the calculation.
/NODC=*val*	Suppresses the DC term *val*=1: Removes the DC by subtracting the average value of the signal before processing and before applying any window function (see /Win below). *val*=2: Suppresses the DC term by setting it equal to the second term in the FFT array.

val=0: Computes the DC term using the FFT (default).

/NOR=*N* Sets the normalization, N, in the periodogram equation. By default, it is the number of data points times the square norm of the window function (if any).

N=0 or 1: Skips default normalization.

Any other value of *N* is used as the only normalization.

/Q Quiet mode; suppresses printing in the history area.

/SEGN={*ptsPerSegment*, *overlapPts*}

Use this flag to compute the periodogram, cross-spectral density or degree of coherence by averaging over multiple segments taken from the input waves. The size of each interval is *ptsPerSegment*. *overlapPts* determines the number of points at the end of each interval that are included in the next segment.

/R=[*startPt*, *endPt*] Calculates the periodogram for a limited range of the wave. *startPt* and *endPt* are expressed in terms of point numbers in *srcWave*.

/R=(*startX*, *endX*) Calculates the periodogram for a limited range of the wave. *startX* and *endX* are expressed in terms of x-values. Note that this option will convert your x-specifications to point numbers and some roundoff may occur.

/WIN=*windowKind* Specifies the window type. If you omit the /W flag, DSPPeriodogram uses a rectangular window for the full wave or the range of data selected by the /R flag.

Choices for *windowKind* are:

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.

See **FFT** for window definition details.

/Z Do not report errors. When an error occurs, V_flag is set to -1.

Details

The default periodogram is defined as

$$Periodogram = \frac{|F(s)|^2}{N},$$

where F (s) is the Fourier transform of the signal s and N is the number of points.

In most practical situations you need to account for using a window function (when computing the Fourier transform) which takes the form

$$Periodogram = \frac{|F(s \cdot w)|^2}{N_p N_w},$$

where w is the window function, N_p is the number of points and N_w is the normalization of the window function.

If you compute the periodogram by subdividing the signal into multiple segments (with any overlap) and averaging the results over all segments, the expression for the periodogram is

$$Periodogram = \frac{\sum_{i=1}^{M} |F(s_i \cdot w)|^2}{M N_s N_w},$$

where si is the ith segment s, Ns is the number of points per segment and M is the number of segments.

When calculating the cross-spectral density (csd) of two waves s_1 and s_2, the operation results in a complex valued wave

$$csd = \frac{F(s_A)[F(s_B)]^*}{N},$$

which contains the normalized product of the Fourier transform of the first wave S_A with the complex conjugate of the Fourier transform of the second wave S_B. The extension of the csd calculation to segment averaging has the form

$$csd = \frac{\sum_{i=0}^{M} F(s_{Ai})[F(s_{Bi})]^*}{MN_sN_w},$$

where S_{Ai} is the ith segment of the first wave, M is the number of segments and N_s is the number of points in a segment.

The degree of coherence is a normalized version of the cross-spectral density. It is given by

$$\gamma = \frac{\sum_{i=0}^{M} F(s_{Ai})[F(s_{Bi})]^*}{\sqrt{\sum_{i=0}^{M} F(s_{Ai})[F(s_{Ai})]^* \sum_{i=0}^{M} F(s_{Bi})[F(s_{Bi})]^*}}.$$

The bias in the degree of coherence is calculated using the approximation

$$B = \frac{1}{M}\left[1 - |\gamma|^2\right]^2.$$

The bias is stored in the wave W_Bias.

If you use the /SEGN flag the actual number of segments is reported in the variable V_numSegments.

Note that DSPPeriodogram does not test the dimensionality of the wave; it treats the wave as 1D. When you compute the cross-spectral density or the degree of coherence the number-type, dimensionality and the scaling of the two waves must agree.

Duplicate

Duplicate [***flags***][***type flags***] ***srcWaveName, destWaveName*** [**,** ***destWaveName***]…

The Duplicate operation creates new waves, the names of which are specified by *destWaveName*s and the contents, data type and scaling of which are identical to *srcWaveName*.

Parameters

srcWaveName must be the name of an existing wave.

The *destWaveNames* should be wave names not currently in use unless the /O flag is used to overwrite existing waves.

Flags

/FREE — Creates a free wave (see **Free Waves** on page IV-71).
/FREE is allowed only in functions and only if a simple name or structure field is specified as the destination wave name.
Requires Igor Pro 6.1 or later. For advanced programmers only.

/O — Overwrites existing waves with the same name as *destWaveName*.

/R=(*startX*,*endX*) — Specifies an X range in the source wave from which the destination wave is created. See Details for further discussion of /R.

/R=(*startX*,*endX*)(*startY*,*endY*)
Specifies both X and Y range. Further dimensions are constructed analogously. See Details for further discussion of /R.

/R=[*startP*,*endP*] — Specifies a row range in the source wave from which the destination wave is created. Further dimensions are constructed just like the scaled dimension ranges. See Details for further discussion of /R.

Type Flags *(used only in functions)*

When used in user-defined functions, Duplicate can also take the /B, /C, /D, /I, /S, /U, /W, /T, /DF and /WAVE flags. This does not affect the result of the Duplicate operation - these flags are used only to identify what kind of wave is expected at runtime.

This information is used if, later in the function, you create a wave assignment statement using a duplicated wave as the destination:

```
Function DupIt(wv)
    Wave/C wv                   //complex wave

    Duplicate/O/C wv,dupWv      //tell Igor that dupWv is complex
    dupWv[0]=cmplx(5.0,1.0)     //no error, because dupWv known complex
    …
```

If Duplicate did not have the /C flag, Igor would complain with a "function not available for this number type" message when it tried to compile the assignment of dupWv to the result of the cmplx function.

These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-58 and **WAVE Reference Type Flags** on page IV-58 for a complete list of type flags and further details.

Details

If /R is omitted, the entire wave is duplicated.

In the range specifications used with /R, a `*` for the end means duplicate to the end. You can also simply leave out the end specification. To include all of a given dimension, use `/R=[]`. If you leave off higher dimensions, all those dimensions are duplicated. That is, `/R=[1,5]` for a 2D wave is equivalent to `/R=[1,5][]`.

Warning: Under some circumstances, such as in loops in user-defined functions, Duplicate may exhibit undesired behavior.

When you use

```
Duplicate/O srcWave, DestWaveName
```

in a user-defined function, it creates a local WAVE variable named *DestWaveName* at compile time. At runtime, if the WAVE variable is NULL, it creates a wave of the same name in the current data folder. If, however, the WAVE variable is not NULL, as it would be in a loop, then the referenced wave will be overwritten no matter where it is located. If the desired behavior is to create (or overwrite) a wave in the current data folder, you should use one of the following two methods:

```
Duplicate/O srcWave, $"DestWaveName"
WAVE DestWaveName   // only if you need to reference dest wave
```

or

```
Duplicate/O srcWave, DestWaveName
// then after you are finished using DestWaveName…
WAVE DestWaveName=$""
```

See Also

The **Rename** operation.

DuplicateDataFolder

DuplicateDataFolder *sourceDataFolderSpec, destDataFolderSpec*

The DuplicateDataFolder operation makes a copy of the source data folder and everything in it and places the copy at the specified location with the specified name.

Parameters

sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

destDataFolderSpec can be just a data folder name, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name. If just a data folder name is used then the new data folder is created in the current data folder.

Details

An error is issued if the destination is contained within the source data folder.

Examples

Create a copy of foo named foo2 in bar:

```
DuplicateDataFolder foo,:bar:foo2
```

See Also

See the **MoveDataFolder** operation. Chapter II-8, **Data Folders**.

DWT

DWT [***flags***] ***srcWaveName, destWaveName***

The DWT operation performs discrete wavelet transform on the input wave *srcWaveName*. The operation works on one or more dimensions only as long as the number of elements in each dimension is a power of 2 or when the /P flag is specified

Flags

/D Denoises the source wave. Performs the specified wavelet transform in the forward direction. It then zeros all transform coefficients whose magnitude fall below a given percentage (specified by the /V flag) of the maximum magnitude of the transform. It then performs the inverse transform placing the result in *destWaveName*. The /I flag is incompatible with the /D flag.

/I Perform the inverse wavelet transform. The /S and /D flags are incompatible with the /I flag.

/N=*num* Specifies the number of wavelet coefficients. See /T flag for supported combinations.

/P=*num* *num*=1: Adds zero padding to the end of the dimension up to nearest power of 2 when the number of data elements in a given dimension of *srcWaveName* is not a power of 2.

num=2: Uses zero padding to compute the transform, but the resulting wave is truncated to the length of the input wave.

/S Smooths the source wave. This performs the specified wavelet transform in the forward direction. It then zeros all transform coefficients except those between 0 and the cut-off value (specified in % by /V flag). It then performs the inverse transform placing the result in *destWaveName*. The /I flag is incompatible with the /S flag.

/T=*type* Performs the wavelet transform specified by *type*. The following table gives the transform name with the *type* code for the transform and the allowed values of the *num* parameter used with the /N flag. "NA" means that the /N flag is not applicable to the corresponding transform.

Wavelet Transform	***type***	***num***
Daubechies	1 (default)	4, 6, 8, 10, 12, 20
Haar	2	NA
Battle-Lemarie	4	NA
Burt-Adelson	8	NA

Wavelet Transform	*type*	*num*
Coifman	16	2, 4, 6
Pseudo-Coifman	32	NA
splines	64	1 (2-2), 2 (2-4), 3 (3-3), 4 (3-7)

/V=*value* Specifies the degree of smoothing with the /S and /D flags only.

For /S, *value* gives the cutoff as a percentage of data points above which coefficients are set to zero. For /D, *value* specifies the percentage of the maximum magnitude of the transform such that coefficients smaller than this value are set to zero.

Details

If *destWaveName* exists, DWT overwrites it; if it does not exist, DWT creates it.

When used in a function, the DWT operation automatically creates a wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-56 for details.

If *destWaveName* is not specified, the DWT operation stores the results in W_DWT for 1D waves and M_DWT for higher dimensions.

When working with 1D waves, the transform results are packed such that the higher half of each array contains the detail components and the lower half contains the smooth components and each successive scale is packed in the lower elements. For example, if the source wave contains 128 points then the lowest scale results are stored in elements 64-127, the next scale (power of 2) are stored from 32-63, the following scale from 16-31 etc.

Example

```
Make/O/N=1024 testData=sin(x/100)+gnoise(0.05)
DWT /S/N=20/V=25 testData, smoothedData
```

See Also

For continuous wavelet transforms use the **CWT** operation. See the **FFT** operation.

For further discussion and examples see **Discrete Wavelet Transform** on page III-247.

e

e

The e function returns the base of the natural logarithm system (2.7182818…).

EdgeStats

EdgeStats [***flags***] ***waveName***

The EdgeStats operation produces simple statistics on a region of a wave that is expected to contain a single edge. If more than one edge exists, EdgeStats works on the first one found.

Flags

/A=*avgPts* Determines *startLevel* and *endLevel* automatically by averaging *avgPts* points at centered at *startX* and *endX*. Default is /A=1.

/B=*box* Sets box size for sliding average. This should be an odd number. If /B=*box* is omitted or *box* equals 1, no averaging is done.

/F=*frac* Specifies levels 1, 2 and 3 as a fraction of (*endLevel-startLevel*):

level1 = *frac** (*endLevel-startLevel*) + *startLevel*

level2 = 0.5 * (*endLevel-startLevel*) + *startLevel*

level3 = (1-*frac*) * (*endLevel-startLevel*) + *startLevel*

The default value for *frac* is 0.1 which makes level1 the 10% level, level2 the 50% level and level3 the 90% level.

frac must be between 0 and 0.5.

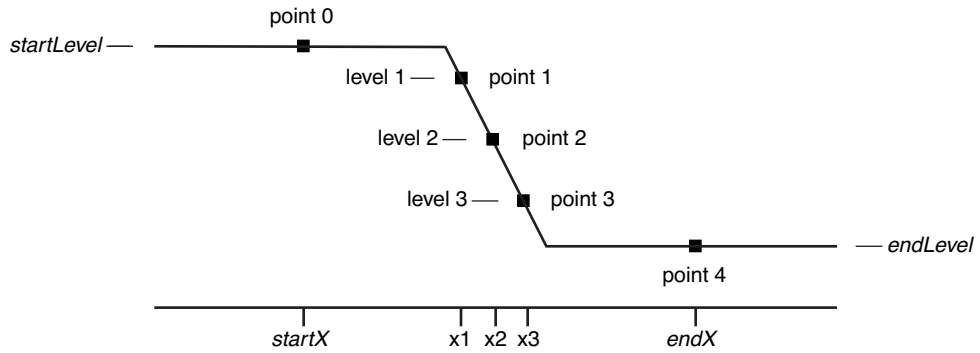
/L=(*startLevel*, *endLevel*)

Sets *startLevel* and *endLevel* explicitly. If omitted, they are determined automatically. See /A.

/P	Output edge locations (see **Details**) are returned as point numbers. If /P is omitted, edge locations are returned as X values.
/Q	Prevents results from being printed in history and prevents error if edge is not found.
/R=(*startX*,*endX*)	Specifies an X range of the wave to search. You may exchange *startX* and *endX* to reverse the search direction.
/R=[*startP*,*endP*]	Specifies a point range of the wave to search. You may exchange *startP* and *endP* to reverse the search direction. If /R is omitted, the entire wave is searched.
/T=*dx*	Forces search in two directions for a possibly more accurate result. *dx* controls where the second search starts.

Details

The /B=*box*, /T=*dx*, /P, and /Q flags behave the same as for the **FindLevel** operation.



EdgeStats considers a region of the input wave between two X locations, called *startX* and *endX*. *startX* and *endX* are set by the /R=(*startX*,*endX*) flag. If this flag is missing, *startX* and *endX* default to the start and end of the entire wave. *startX* can be greater than *endX* so that the search for an edge can proceed from the "right" to the "left".

The diagram above shows the default search direction, from the "left" (lower point numbers) of the wave toward the "right" (higher point numbers).

The *startLevel* and *endLevel* values define the base levels of the edge. You can explicitly set these levels with the /L=(*startLevel*, *endLevel*) flag or you can let EdgeStats find the base levels for you by using the /A=*avgPts* flag which averages points around *startX* and *endX*.

Given *startLevel* and *endLevel* and a *frac* value (see the /F=*frac* flag) EdgeStats defines level1, level2 and level3 as shown in the diagram above. With the default *frac* value of 0.1, level1 is the 10% point, level2 is the 50% point and level3 is the 90% point.

With these levels defined, EdgeStats searches the wave from *startX* to *endX* looking for level2. Having found it, it then searches for level1 and level3. It returns results via variables described below.

EdgeStats sets the following variables:

`V_flag`	0: All three level crossings were found. 1: One or two level crossings were found. 2: No level crossings were found.
`V_EdgeLoc1`	X location of level1.
`V_EdgeLoc2`	X location of level2.
`V_EdgeLoc3`	X location of level3.
`V_EdgeLvl0`	*startLevel* value.
`V_EdgeLvl1`	level1 value.
`V_EdgeLvl2`	level2 value.
`V_EdgeLvl3`	level3 value.
`V_EdgeLvl4`	*endLevel* value.
`V_EdgeAmp4_0`	Edge amplitude (*endLevel - startLevel*).
`V_EdgeDLoc3_1`	Edge width (x distance between point 1 and point 3).

V_EdgeSlope3_1 Edge slope (straight line slope from point 1 and point 3).

These X locations and distances are in terms of the X scaling of the named wave unless you use the /P flag, in which case they are in terms of point number.

The EdgeStats operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

See Also
The **FindLevel** operation for use of the /B=*box*, /T=*dx*, /P and /Q flags, and **PulseStats**.

Edit

Edit [***flags***] [***columnSpec*** [**,** ***columnSpec***]…][**as** ***titleStr***]
The Edit operation creates a table window or subwindow containing the specified columns.

Parameters
columnSpec is usually just the name of a wave. If no *columnSpec*s are given, Edit creates an empty table.

Column specifications are wave names optionally followed by one of the suffixes:

Suffix	Meaning
.i	Index values.
.l	Dimension labels.
.d	Data values.
.id	Index and data values.
.ld	Dimension labels and data values.

If the wave is complex, the wave names may be followed by .real or .imag suffixes. However, as of Igor Pro 3.0, both the real and imaginary columns are added to the table together — you can not add one without the other — so using these suffixes is discouraged.

Historical Note:
Prior to Igor Pro 3.0, only 1D waves were supported. We called index values "X values" and used the suffix ".x" instead of ".i". We called data values "Y values" and used the suffix ".y" instead of ".d". For backward compatibility, Igor accepts ".x" in place of ".i" and ".y" in place of ".d".

titleStr is a string expression containing the table's title. If not specified, Igor will provide one which identifies the columns displayed in the table.

Flags

/HIDE=*h* Hides (h = 1) or shows (h = 0, default) the window.

/HOST=*hcSpec* Embeds the new table in the specified host window or subwindow *hcSpec*.
When identifying a subwindow with *hcSpec*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

/I Specifies that /W coordinates are in inches.

/K=*k* Specifies window behavior when the user attempts to close it.
k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.
k=3: Hides the window.
If you use /K=2 or /K=3, the only way to kill the window is via the DoWindow/K operation.

/M Specifies that /W coordinates are in centimeters.

/N=*name* Requests that the created table have this name, if it is not in use. If it is in use, then *name*0, *name*1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen table name. Use `DoWindow/K name` to ensure that *name* is available.

/W=(*left*,*top*,*right*,*bottom*)

Gives the table a specific location and size on the screen. Coordinates for /W are in points unless /I or /M are specified before /W.

When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings:

1) When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.
2) When any value is greater than 1, coordinates are taken to be fixed locations measured in points relative to the top left corner of the host frame.

Details

You can not change dimension index values shown in a table. Use the Change Wave Scaling dialog or the **SetScale** operation.

If /N is not used, Edit automatically assigns to the table window a name of the form "Table*n*", where *n* is some integer. In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the table from a procedure. Use the **RenameWindow** operation to rename the graph.

Examples

These examples assume that the waves are 1D.

```
Edit myWave,otherWave      // 2 columns: data values from each wave
Edit myWave.id             // 2 columns: x and data values
Edit cmplxWave             // 2 columns: real and imaginary data values
Edit cmplxWave.i           // One column: x values
```

The following examples illustrates the use of column name suffixes in procedures when the name of the wave is in a string variable.

```
Macro TestEdit()
   String w = "wave0"
   Edit $w                 // edit data values
   Edit $w.i               // show index values
   Edit $w.id              // index and data values
End
```

Note that the suffix, if any, must not be stored in the string. In a user-defined function, the syntax would be slightly different:

```
Function TestEditFunction()
   Wave w = $"wave0"
   Edit w                  // no $, because w is name, not string
   Edit w.i                // show index values
   Edit w.id               // index and data values
End
```

The **Structure** keyword.

endtry

endtry
The endtry flow control keyword defines the end of a try-catch-entry flow control construct.

See Also
The **try-catch-endtry** flow control statement for details.

enoise

enoise(*num* [, *RNG*])
The enoise function returns a random value drawn from a uniform distribution having a range of [-*num*, *num*).

The random number generator is initialized using the system clock when you start Igor, virtually guaranteeing that you will never repeat the same sequence. If you want repeatable "random" numbers, use **SetRandomSeed**.

The optional parameter *RNG* selects one of two different pseudo-random number generators. If omitted, the default is 1. The *RNG*'s are:

RNG	Description
1	Linear Congruential generator by L'Ecuyer with added Bayes-Durham shuffle. The algorithm is described in *Numerical Recipes* as the function `ran2()`. This option has nearly 23^2 distinct values and the sequence of random numbers has a period in excess of 10^{18}.
2	Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of 2^{19937}-1.

See Also
The **SetRandomSeed** operation and the **gnoise** function.

Noise Functions on page III-332.

EqualWaves

EqualWaves(*waveA, waveB, selector* [, *tolerance*])

TheEqualWaves function compares *waveA* to *waveB*. Each wave can be of any data type. It returns 1 for equality and zero otherwise.

Use the *selector* parameter to determine which aspects of the wave are compared. You can add *selector* values to test more than one field at a time or pass -1 to compare all aspects.

selector	Field Compared
1	Wave data
2	Wave data type
4	Wave scaling
8	Data units
16	Dimension units
32	Dimension labels
64	Wave note
128	Wave lock state
256	Data full scale
512	Dimension sizes

If you use the selectors for wave data, wave scaling, dimension units, dimension labels or dimension sizes, EqualWaves will return zero if the waves have unequal dimension sizes. The other selectors do not require equal dimension sizes.

Details

If you are testing for equality of wave data and if the *tolerance* is specified, it must be a positive number. The function returns 1 for equality if the data satisfies:

$$\sum_i \left(waveA[i] - waveB[i]\right)^2 < tolerance.$$

If *tolerance* is not specified, it defaults to 10^{-8}.

If *tolerance* is set to zero and *selector* is set to 1 then the data in the two waves undergo a binary comparison (byte-by-byte).

If *tolerance* is non-zero then the presence of NaNs at a given point in both waves does not contribute to the sum shown in the equation above when both waves contain NaNs at the same point. A NaN entry that is present in only one of the waves is sufficient to flag inequality. Similarly, INF entries are excluded from the tolerance calculation when they appear in both waves at the same position and have the same signs.

If you are comparing wave data (selector =1) and both waves contain zero points the function returns 1.

See Also

The **MatrixOp** operation equal keyword.

erf

erf(*num* [, *accuracy*])

The erf function returns the error function of *num*.

$$erf(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.$$

Optionally, *accuracy* can be used to specify the desired fractional accuracy.

In complex expressions the error function is

$$erf(z) = \frac{2z}{\sqrt{\pi}}{}_1F_1(\frac{1}{2},\frac{3}{2},-z^2) \text{ where } {}_1F_1(\frac{1}{2},\frac{3}{2},-z^2)$$

is the confluent hypergeometric function of the first kind HyperG1F1. In this case the accuracy parameter is ignored.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7}, that means that you wish that the absolute value of $(f_{actual} - f_{returned})/f_{actual}$ be less than 10^{-7}.

For backwards compatibility, in the absence of *accuracy* an alternate calculation method is used that achieves fractional accuracy better than about $2x10^{-7}$.

If *accuracy* is present, erf can achieve fractional accuracy better than $8x10^{-16}$ for *num* as small as 10^{-3}. For smaller *num* fractional accuracy is better than $5x10^{-15}$.

Higher accuracy takes somewhat longer to calculate. With *accuracy* set to 10^{-16} erfc takes about 50% more time than with *accuracy* set to 10^{-7}.

See Also

The **erfc**, **erfcw**, **dawson**, **inverseErf**, and **inverseErfc** functions.

erfc

erfc(*num* [, *accuracy*])

The erfc function returns the complementary error function of *num* (erfc(x) = 1 - erf(x)). Optionally, *accuracy* can be used to specify the desired fractional accuracy.

In complex expressions the complementary error function is

$$erfc(z) = 1 - erfc(z) = 1 - \frac{2z}{\sqrt{\pi}}{}_1F_1(\frac{1}{2},\frac{3}{2},-z^2) \text{ where } {}_1F_1(\frac{1}{2},\frac{3}{2},-z^2)$$

is the confluent hypergeometric function of the first kind HyperG1F1. In this case the accuracy parameter is ignored.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7}, that means that you wish that the absolute value of $(f_{actual} - f_{returned})/f_{actual}$ be less than 10^{-7}.

For backwards compatibility, in the absence of *accuracy* an alternate calculation method is used that achieves fractional accuracy better than $2x10^{-7}$.

If *accuracy* is present, erfc can achieve fractional accuracy better than $2x10^{-16}$ for *num* up to 1. From *num* = 1 to 10 fractional accuracy is better than $2x10^{-15}$.

Higher accuracy takes somewhat longer to calculate. With *accuracy* set to 10^{-16} erfc takes about 50% more time than with *accuracy* set to 10^{-7}.

See Also

The **erf**, **erfcw**, **inverseErfc**, and **dawson** functions.

erfcw

erfcw(z)

The erfcw is a complex form of the error function defined by

$$\text{erfcw}(z) = \exp[-z^2]\text{erfc}(-iz),$$

where

$$\mathrm{erfc}(z) = \frac{2}{\sqrt{\pi}} \int_{z}^{\infty} \exp[-t^2]dt.$$

The function is computed with accuracy of 0.5e-10. It is particularly useful for large |z| where the computation of erfc(*z*) starts encountering numerical instability.

See Also

The **erf**, **erfc**, **inverseErfc**, and **dawson** functions.

ErrorBars

ErrorBars [***flags***] ***traceName, mode*** [***errorSpecification***]

The ErrorBars operation adds or removes error bars to or from the named trace in the specified graph.

The "error bars" are lines that extend from each data point to "caps". The length of the line (or "bar") is usually used to bracket a measured value by the amount of uncertainty, or "error" in the measurement.

Parameters

traceName is usually the name of a wave. If a wave is displayed more than once in a graph, the instance number can be appended to identify which instance to apply error bars to. For instance, wave0#2 refers to the third instance of wave0 displayed in the top graph (wave0, or wave0#0, is the first instance).

A string containing *traceName* can be used with the $ operator to specify *traceName*.

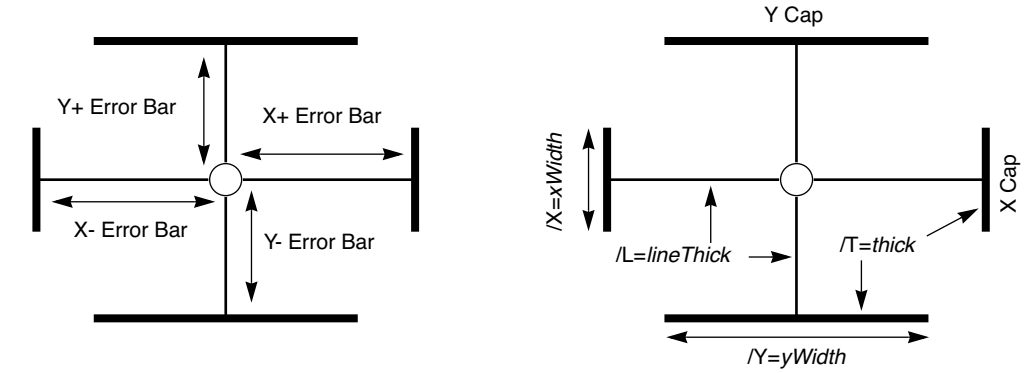
mode is one of the following keywords:

OFF	No error bars.
X	Horizontal error bars only.
Y	Vertical error bars only.
XY	Horizontal and vertical error bars.
BOX	Box error bars.

For any *mode* other than OFF, there is an *errorSpecification* whose format is ***keyword*** [**=** ***value***]. The *errorSpecification* keywords are:

pct	Percent.
sqrt	Square root.
const	Constant.
wave	Arbitrary error values. You can use subranges; see **Subrange Display Syntax** on page II-288.

See the examples for the values that correspond to these *mode* and *errorSpecification* keywords. See the diagram below. *mode* and *errorSpecification* control only the lengths of the horizontal and vertical lines (the "bars") to the "caps". All other sizes and thicknesses are controlled by the flags.



XY *mode* Error Bars

Flags

/L=*lineThick*	Specifies the thickness of both the X and Y error bars drawn from the point on the wave to the caps.
/T=*thick*	Specifies the thickness of both the X and Y error bar "caps".
/W=*winName*	Changes error bars in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.
/X=*xWidth*	Specifies the width (height, actually) of the caps to the left or right of the point.
/Y=*yWidth*	Specifies the width of the caps above or below the point.

The thicknesses and widths are in units of points. The thickness parameters need not be integers. Although only integral thicknesses can be displayed exactly on the screen, nonintegral thicknesses are produced properly on high resolution hard copy devices. Use /T=0 to completely suppress the caps and /L=0 to completely suppress the lines to the caps.

Details

If a point in *traceName* is not within the graph's axes (because the graph has been expanded) then that point's error bars are not shown. If a wave specifying error values for *traceName* is shorter than the wave displayed by *traceName* then the last value of the error wave is used for the unavailable points. If a point in an error wave contains NaN (Not a Number) then the half-bar associated with that point is not shown.

Examples

`ErrorBars wave1,XY pct=10,pct=5`	X and Y error bars, X is 10% of `wave1`, Y is 5%
`ErrorBars wave1,X sqrt`	X error bars only, square root of `wave1`
`ErrorBars wave1,Y const=4.3`	Y error bars only, constant error value = 4.3
`ErrorBars wave1,BOX pct=10,pct=5`	error box, 10% in horizontal direction 5% in vertical direction
`ErrorBars wave1,Y wave=(w1,w2)`	Y error bars only, arbitrary error values wave `w1` = errors for upper (Y+) bars wave `w2` = errors for lower (Y-) bars
`ErrorBars wave1,Y wave=(,w2)`	Y error bars only, no upper (Y+) error bars wave `w2` = errors for lower bars
`ErrorBars wave1,OFF`	turns error bars for wave1 off

Execute

Execute [**/Q/Z**] ***cmdStr***

The Execute operation executes the contents of *cmdStr* as if it had been typed in the command line.

The most common use of Execute is to call a macro or an external operation from a user-defined function. This is necessary because Igor does not allow you to make such calls directly.

When the /Z flag is used, an error code is placed in V_flag.The error code will be -1 if a missing parameter style macro is called and the user clicks Quit Macro, or zero if there was no error.

Flags

/Q Command is not printed in the command line or history area.

/Z Errors are not fatal and error dialogs are suppressed.

Details

Because the command line and command buffer are limited to 400 characters on a single line, *cmdStr* is likewise limited to a maximum of 400 executable characters.

Do not reference local variables in *cmdStr*. The command is not executed in the local environment provided by a macro or user-defined function.

Execute can accept a string expression containing a macro. The string must start with Macro, Proc, or Window, and must follow the normal rules for macros. All lines must be terminated with carriage returns including the last line. The name of the macro is not important but must exist. Errors will be reported except when using the /Z flag, which will assign V_Flag a nonzero number in an error condition.

Examples

It is a good idea to compose the command to be executed in a local string variable and then pass that string to the Execute operation. This prints the string to the history for debugging:

```
String cmd
sprintf cmd, "GBLoadWave/P=%s/S=%d \"%s\"", pathName, skipCount, fileName
Print cmd       // For debugging
Execute cmd
```

Execute with a macro:

```
Execute "Macro junk(a,b)\rvariable a=1,b=2\r\rprint \"hello from macro\",a,b\rEnd\r"
```

See Also

The Execute Operation on page IV-176 for other uses.

Execute/P

Execute/P [**/Q/Z**] ***cmdStr***

Execute/P is similar to Execute except the command string, *cmdStr*, is not immediately executed but rather is posted to an operation queue. Items in the operation queue execute only when nothing else is happening. Macros and functions must not be running and the command line must be empty.

Flags

/Q Command is not printed in the command line or history area.

/Z No error reporting.

See Also

Operation Queue on page IV-250 for more details on using Execute/P with the operation queue.

ExecuteScriptText

ExecuteScriptText [***flags***] ***textStr***

The ExecuteScriptText operation passes your text to Apple's scripting subsystem for compilation and execution or to the Windows command line.

If the /Z flag is used then a variable named V_flag is created and is set to a nonzero value if an error was generated by the script or zero if no error. The error is not reported to Igor if the /Z flag is used.

On Macintosh: Any results, including error messages, are placed in a string variable named S_value. The /B flag is ignored. The /W flag is ignored and ExecuteScriptText does not return until the script is finished.

On Windows: *textStr* contains the name of the executable file with optional Windows-style path and optional arguments:

[*path*]*executableName* [.exe] [*arg1*]…

If *path* is not given and *executableName* ends with ".exe" or with no extension, Igor locates the executable by searching first the registry and then along the PATH environment variable. If not found, then the Igor Pro Folder directory is assumed.

```
ExecuteScriptText "calc"  // calc.exe, calculator
```

When calling a batch file or other non-*.exe file, supply the full path. If the path (or file name) contains spaces put quotes in the string:

```
ExecuteScriptText "\"C:\\Program Files\\my.bat\""
```

If you use the /W=*waitTime* flag with a positive value for *waitTime*, ExecuteScriptText waits up to that many seconds after submitting the command for the process started by the command to terminate. If the process fails to terminate within that period of time, ExecuteScriptText returns an error.

If you omit the /W flag or if you pass zero for *waitTime*, for GUI programs, ExecuteScriptText returns when the program begins processing messages. For non-GUI programs, ExecuteScriptText returns as soon as the OS returns control to Igor after Igor submits the script text to the OS.

Igor currently can not write to a console application's standard input nor read from its standard output.

Use the /B flag to run the command in the background, keeping Igor as the active application.

S_value is always set to "".

Parameters

textStr must contain a valid AppleScript program or Windows command line.

Flags

/B	Execute Windows command line as a background task.
/W=*waitTime*	This flag is accepted on any platform but has an effect only on Windows. See the description above.
/Z	Script errors are not fatal.

Examples

```
// Macintosh: Convert file.PICT to file.GIF:
String ae = "tell application \"clip2gif\" "
ae += "to save file \"HD:file.PICT\"\r"
ExecuteScriptText/Z ae

// Macintosh: Execute a Unix shell command:
Function/S DemoUnixShellCommand()
    // Paths must be POSIX paths (using /).
    // Paths containing spaces or other nonstandard characters must be single-quoted.
    // See Apple Techical Note TN2065 for more on shell scripting via AppleScript.
    String unixCmd
    unixCmd = "ls '/Applications/Igor Pro Folder'"

    String igorCmd

    sprintf igorCmd, "do shell script \"%s\"", unixCmd
    Print igorCmd                       // For debugging only.

       ExecuteScriptText igorCmd
    Print S_value                       // For debugging only.
    return S_value
End

// Windows: Open MatLab in the background:
ExecuteScriptText/B "C:\\Matlab\\bin\\matlab.exe myFile.m"

// Windows: Pass a script to Windows Script Host:
ExecuteScriptText/W=5 "WScript.exe \"C:\\Test Script.vbs\""

// Windows: Execute a batch file and leave the command window open
ExecuteScriptText "cmd.exe /K \"C:\\mybatch.bat\""
```

See Also
See **AppleScript** on page IV-234.

exists

exists(*objNameStr*)

The exists function returns a number which indicates if *objNameStr* contains the name of an Igor object, function or operation.

Details

objNameStr can optionally include a full or partial path to the object. If the name does not include a path, exists checks for waves, strings and variables in the current data folder.

objNameStr can optionally include a module name or independent module name prefix such as "ProcGlobal#" to check for the existence of functions. As of Igor 6.20 this works for macros as well.

The return values are:

0: Name not in use, or does not conflict with a wave, numeric variable or string variable in the specified data folder.
1: Name of a wave in the specified data folder.
2: Name of a numeric or string variable in the specified data folder.
3: Function name.
4: Operation name.
5: Macro name.
6: User-defined function name.

exists is not aware of local variables or parameters in user-defined functions, however it is aware of local variables and parameters in macros.

objNameStr is a string or string expression, *not* a name.

Examples

```
// Prints 2 if V_flag exists as a global variable in the current data folder:
Print exists("V_Flag")

// Prints 5 if a macro named Graph0 exists. Requires Igor Pro 6.20 or later.
Print exists("ProcGlobal#Graph0")
```

See Also

The **DataFolderExists** and **WaveExists** functions and the **WinType** operation.

exp

exp(*num*)

The exp function returns e^{num}. In complex expressions, *num* is complex, and exp(*num*) returns a complex value.

ExperimentModified

ExperimentModified [*newModifiedState*]

The ExperimentModified operation gets and optionally sets the modified (save) state of the current experiment.

Use this command to prevent Igor from asking you to save the current experiment after you have made changes you do not need to save or, conversely, to force Igor to ask about saving the experiment even though Igor would not normally do so.

The variable V_flag is always set to the experiment-modified state that was in effect before the ExperimentModified command executed: 1 for modified, 0 for not modified.

Parameters

If *newModifiedState* is present, it sets the experiment-modified state as follows:

newModifiedState = 0: Igor will not ask to save the experiment before quitting or opening another experiment, and the Save Experiment menu item will be disabled.

newModifiedState = 1: Igor will ask to save the experiment before quitting or opening another experiment, and the Save Experiment menu item will be enabled.

If *newModifiedState* is omitted, the state of experiment-modified state is not changed.

Details

Executing ExperimentModified 0 on the command line will not work because the command will be echoed to the history area, marking the experiment as modifed. Use the command in a function or macro that does not echo text to the history area.

Examples

The /Q flag is vital: it suppresses printing into the history area which would mark the experiment as modified again.

```
Menu "File"
    "Mark Experiment Modified",/Q,ExperimentModified 1    // Enables "Save Experiment"
    "Mark Experiment Saved",/Q,ExperimentModified 0       // Disables "Save Experiment"
End
```

See Also

The **SaveExperiment** operation, **Menu Definition Syntax** on page IV-107.

expInt

expInt(*n, x*)

The expInt function returns the value of the exponential integral $E_n(x)$:

$$E_n(x) = P\int_1^\infty \frac{e^{-xt}}{t^n}dt \qquad x > 0;\ n = 0, 1, 2, \ldots$$

See Also

The **ei** function.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

expnoise

expnoise(*b*)

The expnoise function returns a pseudo-random value from an exponential distribution whose average and standard deviation are *b* and the probability distribution function is

$$f(x) = \frac{1}{b}\exp\left(-\frac{x}{b}\right).$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

The **SetRandomSeed** operation.

Noise Functions on page III-332.

Chapter III-12, **Statistics** for a function and operation overview.

Extract

Extract [*type flags*] [**/INDX/O**] *srcWave, destWave, LogicalExpression*

The Extract operation finds data in *srcWave* wherever *LogicalExpression* evaluates to TRUE and stores the matching data sequentially in *destWave*, which will be created if it does not already exist.

Parameters

srcWave is the name of a wave.

destWave is the name of a new or existing wave that will contain the result.

LogicalExpression can use any comparison or logical operator in the expression.

Flags

/FREE Creates a free destWave (see **Free Waves** on page IV-71).

/FREE is allowed only in functions and only if a simple name or structure field is specified for destWave.

Requires Igor Pro 6.1 or later. For advanced programmers only.

/INDX Stores the index in *destWave* instead of data from *srcWave*.

/O Overwrites *destWave*.

Type Flags *(used only in functions)*

Extract also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-58 and **WAVE Reference Type Flags** on page IV-58 for a complete list of type flags and further details.

Details

srcWave may be of any type including text.

destWave has the same type as *srcWave*, but it is always one dimensional. With /INDX, the *destWave* type is set to unsigned 32-bit integer and the values represent a linear index into *srcWave* regardless of its dimensionality.

Example

```
Make/O source= x
Extract/O source,dest,source>10 && source<20
print dest
```

Prints the following to the history area:

```
  dest[0]= {11,12,13,14,15,16,17,18,19}
```

See Also

The **Duplicate** operation.

factorial

factorial(*n*)

The factorial function returns *n*!, where *n* is assumed to be a positive integer.

Note that while factorial is an integer-valued function, a double-precision number has 53 bits for the mantissa. This means that numbers over 2^{52} will be accurate to about one part in about $2x10^{16}$. Values of *n* greater than 170 result in overflow and return Inf.

FakeData

FakeData(*waveName*)

The FakeData function puts fake data in the named wave, which must be single-precision float. This is useful for testing things that require changing data before you have the source for the eventual real data. FakeData can be useful in a background task expression.

The FakeData function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

Examples

```
Make/N=200 wave0; Display wave0
SetBackground FakeData(wave0)        // define background task
CtrlBackground period=60, start      // start background task
// observe the graph for a while
CtrlBackground stop                  // stop the background task
```

FastGaussTransform

FastGaussTransform [*flags*] *srcLocationsWave, srcWeightsWave*

The FastGaussTransform operation implements an efficient algorithm for evaluating the discrete Gauss transform, which is given by

$$\boldsymbol{G}(\boldsymbol{y}) = \sum_{i=1}^{n} \boldsymbol{q}_i \exp\left[-\frac{\|\boldsymbol{y}-\boldsymbol{x}_i\|^2}{h}\right]$$

where $\boldsymbol{G}$ is an M-dimensional vector, $\boldsymbol{y}$ is an N-dimensional vector representing the observation position, $\{\boldsymbol{q}_i\}$ are the M-dimensional weights, $\{\boldsymbol{x}_i\}$ are N-dimensional vectors representing source locations, and h is the Gaussian width. The wave M_FGT contains the output in the current data folder.

Flags

/AERR=*aprxErr* Sets the approximate error, which determines how many terms of the Taylor expansion of the Gaussian are used by the calculation. Default value is 1e-5.

/WDTH=*h* Sets the Gaussian width. Default value is 1.

/OUTW=*locWave* Specifies the locations at which the output is computed. *locWave* must have the same number of columns as *srcLocationsWave*. The other /OUT flags are mutually exclusive; you should use only one at any time.

/OUT1={*x1*,*nx*,*x2*}
/OUT2={*x1*,*nx*,*x2*,*y1*,*ny*,*y2*}
/OUT3={*x1*,*nx*,*x2*,*y1*,*ny*,*y2*,*z1*,*nz*,*z2*}
Specifies gridded output of the required dimension. In each case you set the starting and ending values together with the number of intervals in that dimension. You cannot specify an output that does not match the dimensions of the input source.

/Q No results printed in the history area.

/RX=*rx* Sets the maximum radius of any cluster. The clustering algorithm terminates when the maximum radius is less than *rx*. Without /RX, the maximum radius is the same as the maximum radius encountered.

/RY=*ry* Sets the upper bound for the distance between an observation point and a cluster center for which the cluster contributes to the transform value. Default is 5*h*.

/TET=*nTerms* Sets the number of terms in the Taylor expansion. Use /TET to set the number of terms and bypass the default error estimate, which is estimated from the approximate error value (/AERR).

/Z No error reporting.

Details

The discrete Gauss transform can be computed as a direct sum. An exact calculation is practical only for moderate number of sources and observation points and for low spatial dimensionality. With increasing dimensionality and increasing number of sources it is more efficient to take advantage of some properties of the Gaussian function. The FastGaussianTransform operation does so in two ways: It first arranges the sources in N-dimensional spatial clusters so that it is not necessary to compute the contributions of all source points that belong to remote clusters (see **FPClustering**). The second component of the algorithm is an approximation that factorizes the sum into a factor that depends only on source points and a factor that depends only on observation points. The factor that depends only on source points is computed only once while the factor that depends on observation points is evaluated once for each observation point.

The trade-off between computation efficiency and accuracy can be adjusted using multiple parameters. By default, the operation calculates the number of terms it needs to use in the Taylor expansion of the Gaussian. You can modify the default approximate error value using /AERR or you can directly set the number of terms in the expansion using /TET.

FastGaussianTransform supports calculations in dimensions that may exceed the maximum allowed wave dimensionality. *srcLocationsWave* must be a 2D, real-valued single- or double-precision wave in which each row corresponds to a single source position and columns represent the components in each dimension (e.g., a triplet wave would represent 3D source locations). *srcWeightsWave* must have the same number of rows as *srcLocationsWave* and it must be a real-valued single- or double-precision wave. In most applications *srcWeightsWave* will have a single column so that the output $\boldsymbol{G}$ will be scalar. However, if *srcWeightsWave* has multiple columns than $\boldsymbol{G}$ is a vector. This can be handy if you need to test multiple sets of coefficients at one time. If you specify observation points using /OUTW then *locWave* must have the same number of columns as *srcLocationsWave* (the number of rows in the output is arbitrary). The operation does not support wave scaling.

FastOp

FastOp [**/C**] ***destwave*** **=** ***prod1*** [**±** ***prod2*** [**±** ***prod3***]]

The FastOp operation can be used to get improved speed out of certain wave assignment statements. The syntax was designed so that you can simply insert `FastOp` in front of any wave assignment statement that meets the syntax requirements.

Parameters

destWave An existing destination wave for the assignment expression. An error will be reported at runtime if the waves are not all the same length or number type.

prod1, *prod2*, *prod3* Products with the following formats:

*constexpr*wave1*wave2*

or

*constexpr*wave1/wave2*

constexpr may be a literal numeric constant or a constant expression in parentheses. Such expressions are evaluated only once.

Any component in a prod expression may be omitted.

Flags

/C Specifies a complex expression. Only applicable to floating point waves.

Details

Certain combinations are evaluated using faster specific code rather than more general but slower generic code. The following specific formats are given special consideration:

Single or Double Precision Real	Integer
waved = C0	*waved = C0*
*waved = C0 *waveA +C1*	*waved = waveA +C1*
waved = waveA +C1	*waved = waveA +waveB +C2*

In the above, pluses may be minuses and the trailing constant (*C0, C1, C2*) may be omitted.

Note: Integer waves are evaluated using double precision intermediate values except for the aforementioned special cases which are evaluated using the native format.

Typically, FastOp will improve performance by 10 to 40 times. The speed increase will be dependent on the computer and on the length of the waves, with the greatest improvement for waves having 1000 to 100,000 points.

This operation replaces the obsolete FastWaveOps XOP. It has all the capabilities of the XOP and then some and has an easier to read syntax.

Examples

Valid expressions:

```
FastOp waved= 3
FastOp waved= waveA + waveB
FastOp waved= 0.5*waveA + 0.5*waveB
FastOp waved= waveA*waveB
FastOp waved= (2*3)*waveA + 6
FastOp waved= (locvar)*waveA
```

Expressions that are **not** valid:

```
FastOp waved= 3*4
FastOp waved= (waveA + waveB)
FastOp waved= waveA*0.5 + 0.5*waveB
FastOp waved= waveA*waveB/2
FastOp waved= 2*3*waveA + 6
FastOp waved= locvar*waveA
```

See Also
The **MatrixOp** operation for more efficient matrix operations.

faverage

faverage(*waveName* [, *x1, x2*])

The faverage function returns the trapezoidal average value of the named wave from x=*x1* to x=*x2*.

If your data are in the form of an XY pair of waves, see **faverageXY**.

Details

If *x1* and *x2* are not specified, they default to -∞ and +∞, respectively.

If *x1* or *x2* are not within the X range of *waveName*, faverage limits them to the nearest X range limit of *waveName*.

faverage returns the area divided by (*x2*-*x1*). In other words, the X scaling of *waveName* is eliminated when computing the average.

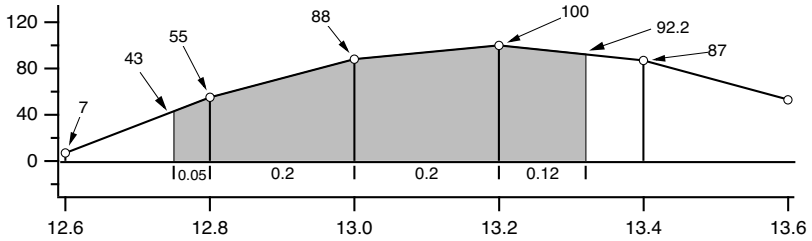
If any Y values in the specified X range are NaN, faverage returns NaN.

Unlike the **area** function, reversing the order of *x1* and *x2* does *not* change the sign of the returned value.

The faverage function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

Examples

Comparison of area, faverage and mean functions over interval (12.75,13.32)



area(wave,12.75,13.32)	= 0.05 · (43+55) / 2	// first trapezoid
	+ 0.20 · (55+88) / 2	// second trapezoid
	+ 0.20 · (88+100) / 2	// third trapezoid
	+ 0.12 · (100+92.2) / 2	// fourth trapezoid
	= 47.082	
faverage(wave,12.75,13.32)	= area(wave,12.75,13.32) / (13.32-12.75)	
	= 47.082/0.57 = 82.6	
mean(wave,12.75,13.32)	= (55+88+100+87)/4 = 82.5	

See Also
Integrate operation and **area** function.

faverageXY

faverageXY(*XWaveName, YWaveName* [, *x1, x2*])

The faverageXY function returns the trapezoidal average value of *YWaveName* from x=*x1* to x=*x2*, using X values from *XWaveName*.

This function operates identically to faverage, except that it uses an XY pair of waves for X and Y values.

Details

If *x1* and *x2* are not specified, they default to -∞ and +∞, respectively.

If *x1* or *x2* are not within the X range of *XWaveName*, faverageXY limits them to the nearest X range limit of *XWaveName*.

faverageXY returns the area divided by (*x2* -*x1*).

If any values in the X range are NaN, faverageXY returns NaN.

Reversing the order of *x1* and *x2* does not change the sign of the returned value.

The values in *XWaveName* may be increasing or decreasing. faverageXY assumes that the values in *XWaveName* are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any X values are NaN, the result is NaN.

The faverageXY function is not multidimensional aware. See Chapter II-6, **Multidimensional Waves** for details on multidimensional waves, particularly **Analysis on Multidimensional Waves** on page II-110.

See Also
See **faverage**, **areaXY**, **area**, and **PolygonArea**.

FBinRead

FBinRead [***flags***] ***refNum, objectName***

The FBinRead operation reads binary data from the file specified by *refNum* into the named object.

Parameters
refNum is a file reference number from the Open operation used to open the file.

objectName is the name of a wave, numeric variable, string variable, or structure.

Flags

/B[=*b*] Specifies file byte ordering.
- *b*=0: Native (same as no /B).
- *b*=1: Reversed (same as /B for compatibility with Igor Pro 3.0).
- *b*=2: Big-endian (Motorola/Macintosh).
- *b*=3: Little-endian (Intel/Windows).

/F=*f* Controls the number of bytes read and how the bytes are interpreted.
- *f*=0: Native binary format of the object (default).
- *f*=1: Signed one-byte integer.
- *f*=2: Signed 16-bit word; two bytes.
- *f*=3: Signed 32-bit word; four bytes.
- *f*=4: 32-bit IEEE floating point.
- *f*=5: 64-bit IEEE floating point.

/U Integer formats (/F=1, 2, or 3) are unsigned. If /U is omitted, integers are signed.

Details
If *objectName* is the name of a string variable then /F doesn't apply. The number of bytes read is the number of bytes in the string *before* the FBinRead operation is called. You can use the **PadString** function to set the size of a string.

The binary format that FBinRead uses for numeric variables or waves depends on the /F flag. If no /F flag is present, the native binary format of the named object is used.

Byte ordering refers to the order in which a multibyte datum is read from a file. For example, a 16-bit word (sometimes called a "short") consists of a high-order byte and a low-order byte. Under big-endian byte ordering, which is commonly used on Macintosh, the high-order byte is read from the file first. Under little-endian byte ordering, which is commonly used on Windows, the low-order byte is read from the file first.

FBinRead will read an entire structure from a disk file. The individual fields of the structure will be byte-swapped if the /B flag is designated.

The FBinRead operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

See Also
The **Open** operation. See **FSetPos** to set positions within files and **FStatus** for file information.

FBinWrite

FBinWrite [***flags***] ***refNum, objectName***

The FBinWrite operation writes the named object in binary to a file.

Parameters

refNum is a file reference number from the **Open** operation used to open the file.

objectName is the name of a wave, numeric variable, string variable, or structure.

Flags

/B[=*b*] Specifies file byte ordering.
- *b*=0: Native (same as no /B).
- *b*=1: Reversed (same as /B for compatibility with Igor Pro 3.0).
- *b*=2: Big-endian (Motorola/Macintosh).
- *b*=3: Little-endian (Intel/Windows).

/F=*f* Controls the number of bytes written and how the bytes are formatted.
- *f*=0: Native binary format of the object (default).
- *f*=1: Signed byte; one byte.
- *f*=2: Signed 16-bit word; two bytes.
- *f*=3: Signed 32-bit word; four bytes.
- *f*=4: 32-bit IEEE floating point.
- *f*=5: 64-bit IEEE floating point.

/P Adds an IgorBinPacket to the data. This is used for PPC or Apple event result packets (*refNum* = 0) and is not normally of use when writing to a file.

/U Integer formats (/F=1, 2, or 3) are unsigned. If /U is omitted, integers are signed.

Details

A zero value of *refNum* is used in conjunction with Program-to-Program Communication (PPC) or Apple events (*Macintosh*) or DDE (*Windows*). The data that would normally be written to a file is appended to the PPC or Apple event or DDE result packet.

If the object is a string variable then /F doesn't apply. The number of bytes written is the number of bytes in the string.

The binary format that FBinWrite uses for numeric variables or waves depends on the /F flag. If no /F flag is present, FBinWrite uses the native binary format of the named object.

Byte ordering refers to the order in which a multibyte datum is written to a file. For example, a 16-bit word (sometimes called a "short") consists of a high-order byte and a low-order byte. Under big-endian byte ordering, which is commonly used on Macintosh, the high-order byte is written to the file first. Under little-endian byte ordering, which is commonly used on Windows, the low-order byte is written to the file first.

FBinWrite will write an entire structure to a disk file. The individual fields of the structure will be byte-swapped if the /B flag is designated.

The FBinWrite operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

See Also

The **Open** operation and Chapter IV-10, **Advanced Programming**. See **FSetPos** to set positions within files and **FStatus** for file information.

FetchURL

FetchURL(*urlStr*)

The FetchURL function returns a string containing the server's response to a request to get the contents of the URL specified by *urlStr*. If *urlStr* contains a URL that uses the file:// scheme, the contents of the local file is returned.

Parameters

urlStr is a string containing the URL to retrieve. You can include a username, password, and server port number as part of the URL.

FetchURL expects that *urlStr* has been percent-encoded if it contains reserved characters. See **Percent Encoding** on page IV-239 for additional information on when percent-encoding is necessary and how to do it.

See **URLs** on page IV-239 for details about how to correctly specify the URL.

FetchURL supports only the http://, ftp://, and file:// schemes. See **Supported Network Schemes** on page IV-239 for details.

There are two special values of *urlStr* that can be used to get information about the network library that Igor uses. The keyword=value pairs returned when *urlStr* is "curl_version_info" may be useful to programmers in that the features and protocols available in the library are specified.

```
FetchURL("curl_version")
FetchURL("curl_version_info")
```

Details

If FetchURL encounters an error, the string it returns a NULL string. You should check for errors before using the returned string. In a user-defined function, use the **GetRTError** function.

```
String urlStr = "http://www.badserver"
String response = FetchURL(urlStr)
Variable error = GetRTError(1)       // Check for error before using response
if (error != 0)
    // FetchURL produced an error
    // so don't try to use the response.
endif
```

Limitations

It is possible for FetchURL to return a valid server response even though the URL you requested does not exist on the server or requires a username and password that you did not provide. In this situation, the response returned by the server will usually be a web page stating that the page was not found or another error message. You can check for this kind of error in your own code by examining the response.

FetchURL does not support advanced features such as network proxies, file or data uploads, or saving the server's response directly to a file. When using the http:// scheme, only the GET method is supported. This means that you cannot use FetchURL to submit form data to a web server that requires using the http POST method.

Encrypted connections using Secure Sockets Layer (SSL) using the https:// scheme are not supported.

Igor Pro is not capable of displaying the contents of a URL in a rendered form like a web browser.

Examples

```

FFT

FFT [*flags*] *srcWave*

The FFT operation computes the Discrete Fourier Transform of *srcWave* using a multidimensional prime factor decomposition algorithm. By default, *srcWave* is overwritten by the FFT.

Output Wave Name

For compatibility with earlier versions of Igor, if you use FFT with no flags or with just the /Z flag, the operation overwrites *srcWave*.

As of Igor Pro 5, if you use any flag other than /Z, FFT uses default output wave names: W_FFT for a 1D FFT and M_FFT for a multidimensional FFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting *srcWave*.

Flags

/COLS Computes the 1D FFT of 2D *srcWave* one column at a time, storing the results in the destination wave.

$$I[t_1][n] = \sum_{k=0}^{N-1} f[t_1][k]\exp\left(i2\pi kn / N\right).$$

You must specify a destination wave using the /DEST flag. No other flags are allowed with this flag. The number of rows must be even. If *srcWave* is a real (NxM) wave, the output matrix will be (1+N/2,M) in analogy with 1D FFT. To avoid changes in the number of points you can convert *srcWave* to complex data type. This flag applies only to 2D source waves. See also the /ROWS flag.

/DEST=*destWave* Specifies the output wave created by the FFT operation.

It is an error to attempt specify the same wave as both *srcWave* and *destWave*.

The default output wave name is W_FFT for a 1D FFT and M_FFT for a multidimensional FFT.

When used in a function, the FFT operation by default creates a complex wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-56 for details.

/HCC Hypercomplex transform (cosine). Computes the integral

$$I_c(\omega_1,\omega_2) = \int_{-\infty}^{\infty}\int f(t_1,t_2)\cos(t_1\omega_1)\exp(it_2\omega_2)dt_1dt_2$$

using the 2D FFT (see **Details**).

/HCS Hypercomplex transform (sine). Computes the integral

$$I_s(\omega_1,\omega_2) = \int_{-\infty}^{\infty}\int f(t_1,t_2)\sin(t_1\omega_1)\exp(it_2\omega_2)dt_1dt_2$$

using the 2D FFT (see **Details**).

/MAG Saves just the magnitude of the FFT in the output wave. See comments under /OUT.

/MAGS Saves the squared magnitude of the FFT in the output wave. See comments under /OUT.

/OUT=*mode* Sets the output wave format.

mode=1: Default for complex output.

mode=2: Real output.

mode=3: Magnitude.

mode=4: Magnitude square.

mode=5: Phase.

mode=6: Scaled magnitude.

mode=7: Scaled magnitude squared.

You can also identify modes 2-4 using the convenience flags /REAL, /MAG, and /MAGS. The convenience flags are mutually exclusive and are overridden by the /OUT flag.

The scaled quantities apply to transforms of real valued inputs where the output is normally folded in the first dimension (because of symmetry). The scaling applies a factor of 2 to the squared magnitude of all components except the DC. The scaled transforms should be used whenever Parseval's relation is expected to hold.

/PAD={*dim1* [, *dim2*, *dim3*, *dim4*]}

Converts *srcWave* into a padded wave of dimensions *dim1*, *dim2*…. The padded wave contains the original data at the start of the dimension and adds zero entries to each dimension up to the specified dimension size. The *dim1*… values must be greater than or equal to the corresponding dimension size of *srcWave*. If you need to pad just the lowest dimension(s) you can omit the remaining dimensions; for example, /Pad=*dim1* will set *dim2* and above to match the dimensions in *srcWave*.

/REAL Saves just the real part of the transform in the output wave. See comments under /OUT.

/ROWS Calculates the FFT of only the first dimension of a 2D *srcWave*. It thus computes the 1D FFT of one row at a time, storing the results in the destination wave.

$$N[n][t_2] = \sum_{k=0}^{M-1} f[k][t_2]\exp(i2\pi kn / M)$$

You must specify a destination wave using the /DEST flag. No other flags are allowed with this flag. The number of columns must be even. If *srcWave* is a real (NxM) wave, the output matrix will be (N,1+M/2) in analogy with 1D FFT. To avoid changes in the number of points you can convert *srcWave* to complex data type. See also /COLS flag.

/RP=[*startPoint*, *endPoint*]

/RX=(*startX*, *endX*) Defines a segment of a 1D *srcWave* that will be transformed. By default the operation transforms the whole wave. It is sometimes useful to take advantage of this feature in order to transform just the defined interval, which includes both end points. You can define the interval using wave point indexing with the /RP flag or using the X-values with the /RX flag. The interval must include at least four data points and the total number of points must be an even number.

/WINF=*windowKind*

Premultiplies a 1D *srcWave* with the selected window function.

In the following window definitions, $w(n)$ is the value of the window function that multiplies the signal, N is the number of points in the signal wave (or range if /R is specified), and n is the wave point index. With /R, n=0 for the first datum in the range.

Choices for *windowKind* are in bold (some windows, in italics, have multiple options for different constant values):

Bartlet: a synonym for Bartlett.

Bartlett: $$w(n) = \begin{cases} \dfrac{2n}{N} & n = 0,1,...\dfrac{N}{2} \\ 2 - \dfrac{2n}{N} & n = \dfrac{N}{2},...N-1 \end{cases}$$

Blackman: $w(n) = a_0 - a_1 \cos\left(\frac{2\pi}{N} n\right) + a_2 \cos\left(\frac{2\pi}{N} 2n\right) - a_3 \cos\left(\frac{2\pi}{N} 3n\right)$.

$n = 0,1,2...N-1.$

windowKind	a_0	a_1	a_2	a_3
Blackman367	0.42323	0.49755	0.07922	
Blackman361	0.44959	0.49364	0.05677	
Blackman492	0.35875	0.48829	0.14128	0.01168
Blackman474	0.40217	0.49703	0.09392	0.00183

Cos:

$$w(n) = \cos\left(\frac{n}{N}\pi\right)^{\alpha},$$

$$n = -\frac{N}{2},...,-1,0,1,...,\frac{N}{2}.$$

Cos1: $\alpha = 1.$
Cos2: $\alpha = 2.$
Cos3: $\alpha = 3.$
Cos4: $\alpha = 4.$

Hamming: $$w(n) = \begin{cases} 0.54 + 0.46\cos\left(\frac{2\pi n}{N}\right) & n = -\frac{N}{2},...,-1,0,1,...,\frac{N}{2} \\ 0.54 - 0.46\cos\left(\frac{2\pi n}{N}\right) & n = 0,1,2,...,N-1 \end{cases}$$

Hanning: $$w(n) = \begin{cases} \frac{1}{2}\left[1 + \cos\left(\frac{2\pi n}{N}\right)\right] & n = -\frac{N}{2},...,-1,0,1,...,\frac{N}{2} \\ \frac{1}{2}\left[1 - \cos\left(\frac{2\pi n}{N}\right)\right] & n = 0,1,2,...,N-1 \end{cases}$$

Kaiser Bessel: $$w(n) = \frac{I_0\left(\pi\alpha\sqrt{1-\left(\frac{2n}{N}\right)^2}\right)}{I_0(\pi\alpha)} \quad 0 \le |n| \le \frac{N}{2}.$$

where I_0 is the zero-order modified Bessel function of the first kind.

KaiserBessel20: $\alpha = 2.$
KaiserBessel25: $\alpha = 2.5.$
KaiserBessel30: $\alpha = 3.$

Parzen: $$w(n) = 1 - \left|\frac{2n}{N}\right|^2 \quad 0 \le |n| \le \frac{N}{2}.$$

Poisson: $$w(n) = \exp\left(-\alpha \frac{2|n|}{N}\right) \qquad 0 \le |n| \le \frac{N}{2}.$$

Poisson2: $\alpha = 2$.
Poisson3: $\alpha = 3$.
Poisson4: $\alpha = 4$.

Riemann: $$w(n) = \frac{\sin\left(\frac{2\pi n}{N}\right)}{\left(\frac{2\pi n}{N}\right)} \qquad 0 \le |n| \le \frac{N}{2}.$$

/Z Disables rotation of the FFT of a complex wave. Igor normally rotates the FFT result (which is also complex) by N/2 so that x=0 is at the center point (N/2). When /Z is specified, Igor does not perform this rotation and leaves x=0 at the first point (0).

Details

The data type of *srcWave* is arbitrary. The first dimension of *srcWave* must be an even number and the minimum length of *srcWave* is four points. When *srcWave* is a double precision wave, the FFT is computed in double precision. All other data types are transformed using single precision calculations. The result of the FFT operation is always a floating point number (single or double precision).

Depending on your choice of outputs, you may not be able to invert the transform in order to obtain the original *srcWave*.

srcWave or any of it's intervals must have at least four data points and must not contain NaNs or INFs.

The FFT algorithm is based on prime number decomposition, which decomposes the number of points in each dimension of the wave into a product of prime numbers. The FFT is optimized for primes < 5. In time consuming applications it is frequently worthwhile to pad the data so that the total number of points factors into small prime numbers.

The hypercomplex transforms are computed by writing the sine and cosine as a sum of two exponentials. Let the 2D Fourier transform of the input signal be

$$F[n_1][n_2] = \sum_{k_1=0}^{N_1-1} \sum_{k_2=0}^{N_2-1} f[k_1][k_2] \exp\left(i2\pi k_1 \frac{n_1}{N_1}\right) \exp\left(i2\pi k_2 \frac{n_2}{N_2}\right)$$

then the two hypercomplex transforms are given by

$$I_c[n_1][n_2] = \frac{1}{2}\left(F[n_1][n2] + F[-n_1][n2]\right)$$

and

$$I_s[n_1][n_2] = \frac{1}{2i}\left(F[n_1][n2] - F[-n_1][n2]\right)$$

FIFO2Wave

FIFO2Wave [**/R/S**] ***FIFOName, channelName, waveName***

The FIFO2Wave operation copies FIFO data from the specified channel of the named FIFO into the named wave. FIFOs are used for data acquisition.

Flags

/R=[*startPoint*,*endPoint*] Dumps the specified FIFO points into the wave.

/S=*s*
- *s*=0: Same as no /S.
- *s*=1: Sets the wave's X scaling x_0 value to the number of the first sample in the FIFO.
- *s*=2: Changes the wave's number type to match the FIFO channel's type.
- *s*=3: Combination of *s*=1 and *s*=2.

Details

The FIFO must be in the valid state for FIFO2Wave to work. When you create a FIFO, using NewFIFO, it is initially invalid. It becomes valid when you issue the start command via the CtrlFIFO operation. It remains valid until you change a FIFO parameter using CtrlFIFO.

If you specify a range of FIFO data points, using /R=[*startPoint*,*endPoint*] then FIFO2Wave dumps the specified FIFO points into the wave after clipping *startPoint* and *endPoint* to valid point numbers.

The valid point numbers depend on whether the FIFO is running and on whether or not it is attached to a file. If the FIFO is running then *startPoint* and *endPoint* are truncated to number of points in the FIFO. If the FIFO is buffering a file then the range can include the full extent of the file.

If you specify no range then FIFO2Wave transfers the most recently acquired FIFO data to the wave. The number of points transferred is the smaller of the number of points in the FIFO and number of points in the wave.

FIFO2Wave may or may not change the wave's X scaling and number type, depending on the current X scaling and on the /S flag.

Think of the wave's X scaling as being controlled by two values, x_0 and dx, where the X value of point p is x_0 + p*dx. FIFO2Wave always sets the wave's dx value equal to the FIFO's deltaT value (as set by the CtrlFIFO operation). If you use no /S flag, FIFO2Wave does not set the wave's x_0 value nor does it set the wave's number type.

If you are using FIFO2Wave to update a wave in a graph as quickly as possible, the /S=0 flag gives the highest update rate. The other /S values trigger more recalculation and slow down the updating.

If the wave's number type (possibly changed to match the FIFO channel) is a floating point type, FIFO2Wave scales the FIFO data before transferring it to the wave as follows:

```
scaled_value = (FIFO_value - offset) * gain
```

If the FIFO channel's gain is one and its offset is zero, the scaling would have no effect so FIFO2Wave skips it.

If the specified FIFO channel is an image strip channel (one defined using the optional vectPnts parameter to NewFIFOChan), then the resultant wave will be a matrix with the number of rows set by vectPnts and the number of columns set by the number of points described above for one-dimensional waves. To create an image plot that looks the same as the corresponding channel in a Chart, you will need to transpose the wave using **MatrixTranspose**.

See Also

FIFOStatus

FIFOStatus [/Q] ***FIFOName***

The FIFOStatus operation returns miscellaneous information about a FIFO and its channels. FIFOs are used for data acquisition.

Flags

/Q Doesn't print in the history area.

Details

FIFOStatus sets the variable V_flag to nonzero if a FIFO of the given name exists. If the named FIFO does exist then FIFOStatus stores information about the FIFO in the following variables:

V_FIFORunning	Nonzero if FIFO is running.
V_FIFOChunks	Number of chunks of data placed in FIFO so far.
V_FIFOnchans	Number of channels in the FIFO.
S_Info	Keyword-packed information string.

The keyword-packed information string consists of a sequence of sections with the following form: *keyword*:*value*;

You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions. Here are the keywords for S_Info:

Keyword	Type	Meaning
DATE	Number	The date/time when start was issued via CtrlFIFO.
DELTAT	Number	The FIFO's deltaT value as set by CtrlFIFO.
DISKTOT	Number	Current number of chunks written to the FIFO's file.
FILENUM	Number	The output file refNum or review file refNum as set by CtrlFIFO. This will be zero if the FIFO is connected to no file.
NOTE	String	The FIFO's note string as set by CtrlFIFO.
VALID	Number	Zero if FIFO is not valid.

In addition, FIFOStatus writes fields to S_Info for each channel in the FIFO. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named "Pressure" then the following would appear in the S_Info string: NAME4:Pressure.

In the following table, the channel's number is represented by "#".

Keyword	Type	Meaning
FSMINUS#	Number	Channel's minus full scale value as set by NewFIFOChan.
FSPLUS#	Number	Channel's plus full scale value as set by NewFIFOChan.
GAIN#	Number	Channel's gain value as set by NewFIFOChan.
NAME#	String	Name of channel.
OFFSET#	Number	Channel's offset value as set by NewFIFOChan.
UNITS#	String	Channel's units as set by NewFIFOChan.

The **NumberByKey** and **StringByKey** functions for parsing keyword-value strings.

FilterFIR

FilterFIR [***flags***] ***waveName*** [, ***waveName***]…

The FilterFIR operation convolves each *waveName* with automatically-designed filter coefficients or with *coefsWaveName* using time-domain methods.

The automatically-designed filter coefficients are simple lowpass and highpass window-based filters or a maximally-flat notch filter. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first *waveName* or just used to filter the data in *waveName*.

FilterFIR filters data faster than **Convolve** when there are many fewer filter coefficient values than data points in *waveName*.

Note: FilterFIR replaces the obsolete **SmoothCustom** operation.

Parameters

waveName is a destination wave that is overwritten by the convolution of itself and the filter.

waveName may be multidimensional, but only one dimension selected by /DIM is filtered (for two-dimensional filtering, see **MatrixFilter**).

Flags

/COEF [=*coefsWaveName*]

Replaces the first output *waveName* by the filter coefficients instead of the filtered results or, when *coefsWaveName* is specified, replaces the output wave(s) by the result of convolving *waveName* with coefficients in *coefsWaveName*.

coefsWaveName must not be one of the destination *waveName*s. It must be single- or double-precision numeric and one-dimensional.

To avoid shifting the output with respect to the input, *coefsWaveName* must have an odd length with the "center" coefficient in the middle of the wave.

The coefficients are usually symmetrical about the middle point, but FilterFIR does not enforce this.

/DIM=*d*

Specifies the wave dimension to filter.

d=-1: Treats entire wave as 1D (default).

For *d*=0, 1,…, operates along rows, columns, etc.

Use /DIM=0 to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all of the sound samples at a particular time.

/E=*endEffect*

Determines how the ends of the wave (*w*) are handled when fabricating missing neighbor values. *endEffect* has values:

0: Bounce method (default). Uses w[*i*] in place of the missing w[-*i*] and w[*n*-*i*] in place of the missing w[*n*+*i*].

1: Wrap method. Uses w[*n*-*i*] in place of the missing w[-*i*] and vice versa.

2: Zero method. Uses 0 for any missing value.

3: Fill method. Uses w[0] in place of the missing w[-*i*] and w[*n*] in place of the missing w[*n*+*i*].

/HI={*f1*, *f2*, *n*}

Creates a high-pass filter based on the windowing method, using the Hanning window unless another window is specified by /WINF.

f1 and *f2* are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

f1 is the end of the reject band, and *f2* is the start of the pass band:

$0 < f1 < f2 < 0.5$

n is the number of FIR filter coefficients to generate. A larger number gives better stop-band rejection. A good number to start with is 101.

Use both /HI and /LO to create a bandpass filter.

/LO={*f1*, *f2*, *n*}

Creates a low-pass filter. *f1* is the end of the pass band, *f2* is the start of the reject band, and *n* is the number of FIR filter coefficients. See /HI for more details.

/NMF={*fc*, *fw* [, *eps*, *nMult*]}

Creates a maximally-flat notch filter centered at *fc* with a -3dB width of *fw*. *fc* and *fw* are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

The longest filter length allowed is 4001 points, which requires *fw* >= 0.0079 (1.58% of the sampling frequency).

Coefficients at the ends that are smaller than the optional *eps* parameter are removed, making the filter shorter (and faster), though less accurate. The default is 2^{-40}. Use 0 to retain all coefficients, no matter how small, even zero coefficients.

nMult specifies how much longer the filter may be to obtain the most accurate notch frequency. The default is 2 (potentially twice as many coefficients). Set *nMult* <= 1 to generate the shortest possible filter.

The maximally flat notch filter design is based on Zahradník and Vlcek, and uses arbitrary precision math (see **APMath**) to compute the coefficients.

/WINF=*windowKind*

Applies the named "window" to the filter coefficients. Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when many filter coefficients are used.

If /WINF is not specified, the Hanning window is used. For no coefficient filtering, use /WINF=None.

Choices for *windowKind* are (see the **FFT** /WINF flag for window equations and details):

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.

Details

If *coefsWaveName* is specified, then /HI, /LO, and /NMF are ignored.

If more than one of /HI, /LO, and /NMF are specified, the filters are combined using linear convolution. The length of the combined filter is slightly less than the sum of the individual filter lengths.

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length should be small in comparison to the destination waves.

FilterFIR assumes that the middle point of *coefsWaveName* corresponds to the delay = 0 point. The "middle" point number = trunc(numpnts(*coefsWaveName* -1)/2). *coefsWaveName* usually contains the two-sided impulse response of a filter, and usually contains an odd number of points. This is the kind of coefficients data generated by /HI, /LO, and /NMF.

FilterFIR ignores the X scaling of all waves, except when /COEF creates a coefficients wave, which preserves the X scale deltax and alters the leftx value so that the zero-phase (center) coefficient is located at x=0.

Examples

```
// Make test sound from three sine waves
Variable/G fs= 44100                                // Sampling frequency
Variable/G seconds= 0.5                             // Duration
Variable/G n= 2*round(seconds*fs/2)
Make/O/W/N=(n) sound                                // 16-bit integer sound wave
SetScale/p x, 0, 1/fs, "s", sound
Variable/G f1= 200, f2= 1000, f3= 7000
Variable/G a1=100, a2=3000,a3=1500
sound= a1*sin(2*pi*f1*x)
sound += a2*sin(2*pi*f2*x)
sound += a3*sin(2*pi*f3*x)+gnoise(10)               // Add a noise floor

// Compute the sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundMag sound
soundMag= 20*log(soundMag)
SetScale d, 0, 0, "dB", soundMag

// Apply a 5 kHz low-pass filter to the sound wave
Duplicate/O sound, soundFiltered
FilterFIR/E=3/LO={4000/fs, 6000/fs, 101} soundFiltered

// Compute the filtered sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundFilteredMag soundFiltered
```

```
soundFilteredMag= 20*log(soundFilteredMag)
SetScale d, 0, 0, "dB", soundFilteredMag

// Compute the filter's frequency response in dB

Smoothing on page III-255; the **Smooth**, **Convolve**, **MatrixConvolve**, and **MatrixFilter** operations.

FilterIIR

FilterIIR [***flags***] [***waveName***,…]

The FilterIIR operation applies to each *waveName* either the automatically-designed IIR filter coefficients or the IIR filter coefficients in *coefsWaveName*. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first *waveName* or just used to filter the data in *waveName*.

The automatically-designed filter coefficients are bilinear transforms of the Butterworth analog prototype with an optional variable-width notch filter.

To design more advanced IIR filters, see **Designing the IIR Coefficients**.

Parameters

waveName may be multidimensional, but only the one dimension selected by /DIM is filtered (for two-dimensional filtering, see **MatrixFilter**).

waveName may be omitted for the purpose of checking the format of *coefsWaveName*. If the format is detectably incorrect an error code will be returned in V_flag. Use /Z to prevent command execution from stopping.

Flags

/CASC — Specifies that *coefsWaveName* contains cascaded bi-quad filter coefficients. The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form 1 filtering. See **Cascade Details**.

/COEF [=*coefsWaveName*] — Replaces the first output *waveName* by the filter coefficients instead of the filtered results or, when *coefsWaveName* is specified, replaces the output wave(s) by the result of filtering *waveName* with the IIR coefficients in *coefsWaveName*.

coefsWaveName must not be one of the destination *waveName*s. It must be single- or double-precision numeric and two-dimensional.

When used with /CASC, *coefsWaveName* must have 6 columns, containing real-valued coefficients for a product of ratios of second-order polynomials (cascaded bi-quad sections).

If /ZP is specified, it must be complex, otherwise it must be real.

See **Details** for the format of the coefficients in *coefsWaveName*.

/DIM=*d* — Specifies the wave dimension to filter.

d=-1: Treats entire wave as 1D (default).

For *d*=0, 1,…, operates along rows, columns, etc.

Use /DIM=0 to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all of the sound samples at a particular time.

/HI=*fHigh* — Creates a high-pass Butterworth filter with the -3dB corner at *fHigh*. The order of the filter is controlled by the /ORD flag.

fHigh is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

/LO=*fLow* — Creates a low-pass Butterworth filter with the -3dB corner at *fLow*. The /ORD flag controls the order of the filter.

fLow is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

Create bandpass and bandreject filters by specifying both /HI and /LO. For a bandpass filter, set *fLow* > *fHigh*, and for a band reject filter, set *fLow* < *fHigh*.

/N={*fNotch*, *notchQ*} — Creates a notch filter with the center frequency at *fNotch* and a -3dB width of *fNotch*/*notchQ*.

fNotch is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

notchQ is a number greater than 1, typically 10 to 100. Large values produce a filter that "rings" a lot.

/ORD=*order* — Sets the order of the Butterworth filter(s) created by /HI and /LO. The default is 2 (second order), and the maximum is 100.

/Z=*z* — Prevents procedure execution from aborting when an error occurs. Use /Z=1 to handle this case in your procedures using **GetRTError**(1) rather than having execution abort. /Z=0 is the same as no /Z at all.

/ZP — Specifies that *coefsWaveName* contains complex z-domain zeros (in column 0) and poles (in column 1) or, if *coefsWaveName* is not specified, that the first output *waveName* is to be replaced by filter coefficients in the zero-pole format. See **Zeros and Poles Details**.

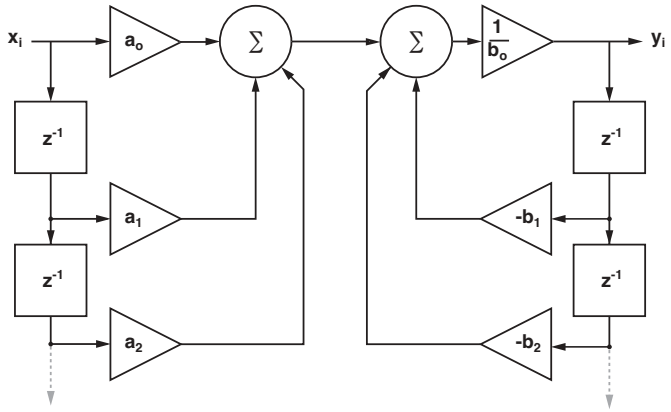
Details

FilterIIR sets V_flag to 0 on success or to an error code if an error occurred. Command execution stops if an error occurs unless the /Z flag is set. Omit /Z and call **GetRTError** and **GetRTErrMessage** under similar circumstances to see what the error code means.

Direct Form 1 Details

Unless /CASC or /ZP are specified, the coefficients in *coefsWaveName* describe a ratio of two polynomials of the Z transform:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2} + \ldots}{b_0 + b_1 z^{-1} + b_2 z^{-2} + \ldots}$$



Direct Form I Implementation

$$y_i = \frac{a_0 x_i + a_1 x_{i-1} + a_2 x_{i-2} + \ldots - b_1 y_{i-1} - b_2 y_{i-2} + \ldots}{b_0}$$

where x is the input wave *waveName* and y is the output wave (either *waveName* again or *destWaveName*).

FilterIIR computes the filtered result using the Direct Form I implementation of $H(z)$.

The rational polynomial numerator (a_i) coefficients in are column 0 and denominator (b_i) coefficients in column 1 of *coefsWaveName*.

The coefficients in row 0 are the nondelayed coefficients a_0 (in column 0) and b_0 (in column 1).

The coefficients in row 1 are the z^{-1} coefficients, a_1 and b_1.

The coefficients in row n are the z^{-n} coefficients, a_n and b_n.

The number of coefficients for the numerator can differ from the number of coefficients for the denominator. In this case, specify 0 for unused coefficients.

Note: If all the coefficients of the denominator are 0 (b_i= 0 except b_0 = 1), then the filter is actually a causal FIR filter (Finite Impulse Response filter with delay of n-1). In this sense, FilterIIR implements a superset of the FilterFIR operation.

Alternate Direct Form 1 Notation

The designation of a_i, etc. as the numerator is at odds with many textbooks such as *Digital Signal Processing*, which uses b for the numerator coefficients of the rational function, a for the denominator coefficients with an implicit a_0 = 1, in addition to reversing the signs of the remaining denominator coefficients so that they can write $H(z)$ as:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{\sum_{i=0}^{n} b_i z^{-i}}{1 - \sum_{i=1}^{n} a_i z^{-i}}.$$

Coefficients derived using this notation need their denominator coefficients sign-reversed before putting them into rows 1 through n of column 1 (the second column), and the "missing" nondelayed denominator coefficient of 1.0 placed in row 0, column 1.

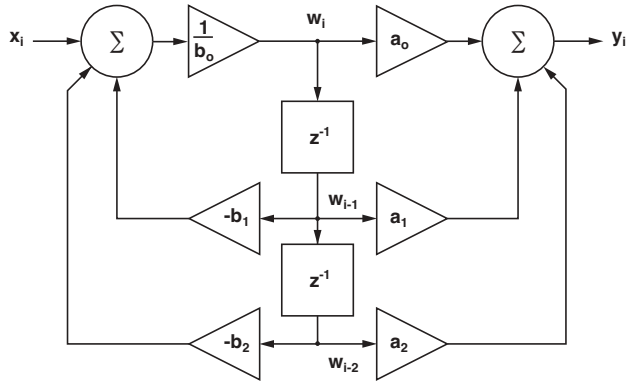
Cascade Details

When using /CASC, coefficients in *coefsWaveName* describe the product of one or more ratios of two quadratic polynomials of the Z transform:

$$H(z) = \frac{Y(z)}{X(z)} = \prod_{k=1}^{k} \frac{a_{0_k} + a_{1_k} z^{-1} + a_{2_k} z^{-2}}{b_{0_k} + b_{1_k} z^{-1} + b_{2_k} z^{-2}}.$$

Each product term implements a "cascaded bi-quad section", and $H(z)$ can be realized by feeding the output of one section to the next one.

The cascade coefficients filter the data using a Direct Form II cascade implementation:



$$w_i = \frac{x_i - b_1 w_{i-1} - b_2 w_{i-2}}{b_0}$$

$$y_i = a_0 w_i + a_1 w_{i-1} + a_2 w_{i-2}$$

Cascaded Bi-Quad Direct Form II Implementation

The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form I filtering. Cascade IIR filtering is recommended when the filter order exceeds 16 (a 16th-order Direct Form I filter has 17 numerator coefficients and 17 denominator coefficients).

coefsWaveName must be a six-column real-valued numeric wave. Each row describes one bi-quad section. The coefficients for the second term (or "section") of the product (*k*=2) are in the following row, etc.:

k	Row	Col 0	Col 1	Col 2	Col 3	Col 4	Col 5
1	0	a_{0_1}	a_{1_1}	a_{2_1}	b_{0_1}	b_{1_1}	b_{2_1}
2	1	a_{0_2}	a_{1_2}	a_{2_2}	b_{0_2}	b_{1_2}	b_{2_2}
	…						

The number of coefficients for the numerator (*a*'s) is allowed to differ from the number of coefficients for the denominator (*b*'s). In this case, specify 0 for unused coefficients.

For example, a third order filter (three poles and three zeros) cascade implementation is a single-order section combined with a second order section. The values for a_{2_k}, b_{2_k} for that section (*k*) would be 0. Here the second section is specified as the first-order section:

k	Row	Col 0	Col 1	Col 2	Col 3	Col 4	Col 5
1	0	a_{0_1}	a_{1_1}	a_{2_1}	b_{0_1}	b_{1_1}	b_{2_1}
2	1	a_{0_2}	a_{1_2}	0	b_{0_2}	b_{1_2}	0

Alternate Cascade Notation

In the DSP literature, the b_{0_k} gain values are typically one and the $H(z)$ expression contains an overall gain value, usually *K*. Here each product term (or "section") has a user-settable gain value. Computing the correct gain values to control overflow in integer implementations is the responsibility of the user. For floating implementations, you might as well set all b_{0_k} values to one except, say, b_{0_1}, to control the overall gain.

Zeros and Poles Details

When using /ZP, coefficients in *coefsWaveName* contains complex zeros and poles in the (also complex) Z transform domain:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{(z-z_0)\bullet(z-z_1)\bullet(z-z_2)\bullet\ldots}{(z-p_0)\bullet(z-p_1)\bullet(z-p_2)\bullet\ldots}.$$

coefsWaveName must be a two-column complex wave with zero0, zero1,… zeroN in the first column of N+1 rows, and pole0, pole1,… poleN in the second column of those same rows:

k	Row	Col 0	Col 1
1	0	(zero0Real, zero0Imag)	(pole0Real, pole0Imag)
2	1	(zero1Real, zero1Imag)	(pole1Real, pole1Imag)
3	2	(zero2Real, zero2Imag)	(pole2Real, pole2Imag)
	…		

If a zero or pole has a nonzero imaginary component, the conjugate zero or pole must be included in *coefsWaveName*. For example, if a zero is placed at (0.7, 0.5), the conjugate is (0.7, -0.5), and that value must also appear in column 0. These two zeros form what is known as a "conjugate pair". The conjugate values must match within the greater of 1.0e-6 or 1.0e-6 * |zeroOrPole|.

Use (0,0) for unused poles or zeros, as a zero or pole at *z*= (0,0) has no effect on the filter frequency response.

The /ZP format for the coefficients is internally converted into the Direct Form 1 implementation, or into the Cascade Direct Form 2 implementation if /CASC is specified. There is no option for returning these implementation-dependent coefficients in a wave.

Designing the IIR Coefficients

Simple IIR filters can be used or created by specifying the /LO, /HI, /ORD, /N, /CASC, and /ZP flags. Use /COEF without *coefsWaveName* to put these simple IIR filter coefficients into the first *waveName*.

More advanced IIR filters (Bessel, Chebyshev) can be designed using the separate IFDL package. IFDL is a suite of extensions and macros that you use to design FIR (Finite Impulse Response) and IIR (Infinite Impulse Response) filters and to apply them to your data. The IIR design software creates IIR coefficients based on bilinear transforms of analog prototype filters such as Bessel, Butterworth, and Chebyshev. See the WaveMetrics web site for more about IFDL.

Even without IFDL, you can create custom IIR filters by manually placing poles and zeros in the Z plane using the Pole and Zero Filter Design procedures. Copy the following line to your Procedure window and click the Compile button at the bottom of the procedure window:

```
#include <Pole And Zero Filter Design>
```

Then choose Pole and Zero Filter Design from the Analysis menu.

Examples

```
// Make test sound from three sine waves
Variable/G fs= 44100                          // Sampling frequency
Variable/G seconds= 0.5                       // Duration
Variable/G n= 2*round(seconds*fs/2)
Make/O/W/N=(n) sound                          // 16-bit integer sound wave
SetScale/p x, 0, 1/fs, "s", sound
Variable/G f1= 200, f2= 1000, f3= 7000
Variable/G a1=100, a2=3000,a3=1500
sound= a1*sin(2*pi*f1*x)
sound += a2*sin(2*pi*f2*x)
sound += a3*sin(2*pi*f3*x)+gnoise(10)             // Add a noise floor

// Compute the sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundMag sound
soundMag= 20*log(soundMag)
SetScale d, 0, 0, "dB", soundMag

// Apply a 5 kHz, 6th order low-pass filter to the sound wave
Duplicate/O sound, soundFiltered
FilterIIR/LO=(5000/fs)/ORD=6 soundFiltered        // Second order by default
```

```
// Compute the filtered sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundFilteredMag soundFiltered
soundFilteredMag= 20*log(soundFilteredMag)
SetScale d, 0, 0, "dB", soundFilteredMag

// Compute the filter's frequency and phase by filtering an impulse
Make/O/D/N=2048 impulse= p==0                    // Impulse at t==0
SetScale/P x, 0, 1/fs, "s", impulse
Duplicate/O impulse, impulseFiltered
FilterIIR/LO=(5000/fs)/ORD=6 impulseFiltered
FFT/MAG/DEST=impulseMag impulseFiltered
impulseMag= 20*log(impulseMag)
SetScale d, 0, 0, "dB", impulseMag
FFT/OUT=5/DEST=impulsePhase impulseFiltered
impulsePhase *= 180/pi                           // Convert to degrees
SetScale d, 0, 0, "deg", impulsePhase
Unwrap 360, impulsePhase                         // Continuous phase

// Graph the frequency responses
Display/R/T impulseMag as "IIR Lowpass Example"

FindDimLabel

FindDimLabel(*waveName, dimNumber, labelString*)

Returns the index value corresponding to the label for the given dimension. Returns -1 if the label is for the entire dimension. Returns -2 if the label is not found.

Use *dimNumber* =0 for rows, 1 for columns, 2 for layers, or 3 for chunks.

FindLevel

FindLevel [***flags***] ***waveName, level***

The FindLevel operation searches the named wave to find the X value at which the specified Y *level* is crossed.

Flags

/B=*box* Sets box size for sliding average. If /B=*box* is omitted or *box* equals 1, no averaging is done. If you specify an even box size then the next higher (odd) integer is used. If you use a box size greater than 1, FindLevel will be unable to find a level crossing that occurs in the first or last *box*/2 -1 points of the wave since these points don't have enough neighbors for computing the derived average wave values.

/EDGE=*e* Specifies searches for either increasing or decreasing level crossing.

- *e*=1: Searches only for crossing where Y values are increasing as *level* is crossed from wave start towards wave end.
- *e*=2: Searches only for crossing where the Y values are decreasing as *level* is crossed from wave start towards wave end.
- *e*=0: Same as no /EDGE flag (searches for either increasing and decreasing level crossing).

/P Computes the X crossing location in terms of point number. If /P is omitted, the level crossing location is computed in terms of X values.

/Q Don't print results in history and don't report error if *level* is not found.

/R=(*startX*,*endX*) Specifies an X range of the wave to search. You may exchange *startX* and *endX* to reverse the search direction.

/R=[*startP*,*endP*] Specifies a point range of the wave to search. You may exchange *startP* and *endP* to reverse the search direction. If you specify the range as /R=[*startP*] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is searched.

/T=*dx* Search for two level crossings. *dx* must be less than *minWidthX*, so you must also specify /M if you use /T. (FindLevel limits *dx* so that second search start isn't beyond where the first search for next edge will be.)

/T=*dx* Performs a second search after finding the initial level crossing. The second search starts *dx* units beyond the initial level crossing and looks back in the direction of the initial crossing. If FindLevel finds a second level crossing, it sets V_LevelX to the average of the initial and second crossings. Otherwise, it sets V_LevelX to the initial crossing.

Details

FindLevel scans through the wave comparing *level* to values derived from the Y values of the wave. Each derived value is a sliding average of the Y values.

FindLevel searches for two derived wave values that straddle *level*. If it finds these values it computes the X value at which *level* is located by linearly interpolating between the straddling Y values.

Note: FindLevel does not locate values exactly equal to *level*; it locates transitions through *level*. See **BinarySearch** for one method of locating exact values.

FindLevel reports its results by setting these variables:

`V_flag`	0: *level* was found. 1: *level* was not found.
`V_LevelX`	Interpolated X value at which *level* was found, or the corresponding point number if /P is specified.
`V_rising`	0: Y values at the crossing are decreasing from wave start towards wave end. 1: Y values at the crossing are increasing.

If you do not use the /Q flag then FindLevel also reports its results by printing them in the history area, and if *level* is not found FindLevel generates an error which puts up an error alert and also halts execution of any command line or macro that is in progress.

These X locations and distances are in terms of the X scaling of the named wave unless you use the /P flag, in which case they are in terms of point number.

V_LevelX is returned in terms of the X scaling of the named wave unless you use the /P flag, in which case it is in terms of point number.

The FindLevel operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

The **EdgeStats**, **FindLevels**, **FindValue**, and **PulseStats** operations and the **BinarySearch** and **BinarySearchInterp** functions.

FindLevels

**`FindLevels [`*`flags`*`] `*`waveName, level`*

The FindLevels operation searches the named wave to find one or more X values at which the specified Y *level* is **crossed**.

To find where the wave is equal to a given value, use **FindValue** instead.

Flags

/B=*box*	Sets box size for sliding average. See the **FindLevel** operation.
/D=*destWaveName*	Specifies wave into which FindLevels is to store the level crossing values. If /D and /DEST are omitted, FindLevels creates a wave named W_FindLevels to store the level crossing values in.
/DEST=*destWaveName*	Same as /D. Added /DEST for Igor 6.13; now the named wave need not pre-exist. Both /D and /DEST create a real wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-56 for details.
/EDGE=*e*	Specifies searches for either increasing or decreasing level crossing. *e*=1: Searches only for crossings where the Y values are increasing as level is crossed from wave start towards wave end. *e*=2: Searches only for crossings where the Y values are decreasing as level is crossed from wave start towards wave end. *e*=0: Same as no /EDGE flag (searches for both increasing and decreasing level crossings).
/M=*minWidthX*	Sets the minimum X distance between level crossings. This determines where FindLevels searches for the next crossing after it has found a level crossing. The search starts *minWidthX* X units beyond the crossing. The default value for *minWidthX* is 0.

/N=*maxLevels*	Sets a maximum number of crossings that FindLevels is to find. The default value for *maxLevels* is the number of points in the specified range of *waveName*.
/P	Compute crossings in terms of points. See the **FindLevel** operation.
/Q	Doesn't print to history and doesn't abort if no levels are found.
/R=(*startX*,*endX*)	Specifies X range. See the **FindLevel** operation.
/R=[*startP*,*endP*]	Specifies point range. See the **FindLevel** operation.
/T=*dx*	Search for two level crossings. *dx* must be less than *minWidthX*, so you must also specify /M if you use /T. (FindLevels limits *dx* so that second search start isn't beyond where the first search for next edge will be.) See **FindLevel** for more about /T.

Details

The algorithm for finding a level crossing is the same one used by the **FindLevel** operation.

If FindLevels finds *maxLevels* crossings or can not find another level crossing, it stops searching.

FindLevels sets the following variables:

`V_flag`	0: *maxLevels* level crossings were found.
	1: At least one but less than *maxLevels* level crossings were found.
	2: No level crossings were found.
`V_LevelsFound`	Number of level crossings found.

Examples

```
// Prior to Igor 6.13, any /D wave had to exist:
Make/O/D/N=0 destWave
FindLevels/Q/D=destWave data, 5
if( V_LevelsFound )
   Print destWave[0]   // First crossing X location

// As of Igor 6.13, /D and /DEST create the destination wave if it does not exist:
FindLevels/Q/D=destWave data, 5
if( V_LevelsFound )
   Print destWave[0]   // First crossing X location
```

See Also

The **FindLevel** operation for details about the level crossing detection algorithm and the /B, /P, /Q, /R, and /T flag values.

The FindLevels operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

FindListItem

FindListItem(*itemStr, listStr* [, *listSepStr* [, *start* [, *matchCase*]]])

The FindListItem function returns a numeric offset into *listStr* where *itemStr* begins. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use FindListItem to locate the start of an item in a string containing a "wave0;wave1;" style list such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

Use WhichListItem to determine the index of an item in the list.

If *itemStr* is not found, if *listStr* is `""`, or if *start* is not within the range of 0 to strlen(*listStr*)-1, then -1 is returned.

listSepStr, *startIndex*, and *matchCase* are optional; their defaults are ";", 0, and 1 respectively.

Details

ItemStr may have any length.

listStr is searched for the first instance of the item string bound by a *listSepStr* on the left and a *listSepStr* on the right. The returned number is the character index where the first character of *itemStr* was found in *listSepStr*.

The search starts from the character position in *listStr* specified by *start*. A value of 0 starts with the first character in *listStr*, which is the default if *start* is not specified.

listString is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are always case-sensitive. The comparison of *itemStr* to the contents of *listStr* is usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparison case insensitive.

Only the first character of *listSepStr* is used.

If *startIndex* is specified, then *listSepStr* must also be specified. If *matchCase* is specified, *startIndex* and *listSepStr* must be specified.

Examples

```
Print FindListItem("w1", "w0;w1;w2,")                // prints 3
Print FindListItem("v2", "v1,v2,v3,", ",")           // prints 3
Print FindListItem("v2", "v0,v2,v2,", ",", 4)        // prints 6
Print FindListItem("C", "a;c;C;")                    // prints 4
Print FindListItem("C", "a;c;C;", ";", 0, 0)         // prints 2
```

FindPeak

FindPeak [***flags***] ***waveName***

The FindPeak operation searches for a minimum or maximum by analyzing the smoothed first and second derivatives of the named wave. Information about the peak position, amplitude, and width are returned in the output variables.

Flags

Some of the flags have the same meaning as for the FindLevel operation.

/B=*box*	Sets box size for sliding average.
/I	Modify the search criteria to accommodate impulses (peaks of one sample) by requiring only one value to exceed *minLevel*. The default criteria requires that two successive values exceed *minLevel* for a peak to be found (or two successive values be less than the /M level when searching for negative peaks). Impulses can also be found by omitting *minLevel*, in which case /I is superfluous.
/M=*minLevel*	Defines minimum level of a peak. /N changes this to maximum level (see **Details**).
/N	Searches for a negative peak (minimum) rather then a positive peak (maximum).
/P	Location output variables (see **Details**) are reported in terms of (floating point) point numbers. If /P is omitted, they are reported as X values.
/Q	Doesn't print to history and doesn't abort if no peak is found.
/R=(*startX*,*endX*)	Specifies X range and direction for search.
/R=[*startP*,*endP*]	Specifies point range and direction for search.

Details

FindPeak sets the following variables:

V_flag	Set only when using the /Q flag. 0: Peak was found. Any nonzero value means the peak was not found.
V_LeadingEdgeLoc	Interpolated location of the peak edge closest to *startX* or *startP*. If you use the /P flag, V_LeadingEdgeLoc is a point number rather than to an X value. If the edge was not found, this value is NaN.
V_PeakLoc	Interpolated X value at which the peak was found. If you use the /P flag, FindPeak sets V_PeakLoc to a point number rather than to an X value. Set to NaN if peak wasn't found.
V_PeakVal	The *approximate* Y value of the found peak. If the peak was not found, this value is NaN (Not a Number).
V_PeakWidth	Interpolated peak width. If you use the /P flag, V_PeakWidth is expressed in point numbers rather than as an X value. V_PeakWidth is never negative. If either peak edge was not found, this value is NaN.

V_TrailingEdgeLoc Interpolated location of the peak edge closest to *endX* or *endP*. If you use the /P flag, V_TrailingEdgeLoc is a point number rather than to an X value. If the edge was not found, this value is NaN.

FindPeak computes the sliding average of the input wave using the BoxSmooth algorithm with the *box* parameter. The peak center is found where the derivative of this smoothed result crosses zero. The peak edges are found where the second derivative of the smoothed result crosses zero. Linear interpolation of the derivatives is used to more precisely locate the center and edges. The peak value is simply the greater of the two unsmoothed values surrounding the peak center (if /N, then the lesser value).

FindPeak is not a high-accuracy measurement routine; it is intended as a simple peak-finder. Use the **PulseStats** operation for more precise statistics.

Without /M, a peak is found where the derivative crosses zero, regardless of the peak height.

If you use the /M=*minLevel* flag, FindPeak ignores peaks that are lower than *minLevel* (i.e., the Y value of a found peak will exceed *minLevel*) in the box-smoothed input wave. If /N is also specified (search for minimum), FindPeak ignores peaks whose amplitude is greater than *minLevel* (i.e., the Y value of a found peak will be *less* than *minLevel*).

Without /I, a peak must have two successive values that exceed *minLevel*. Use /I when you are searching for peaks that may have only one value exceeding *minLevel*.

The search for the peak begins at *startX* (or the first point of the wave if /R is not specified), and ends at *endX* (or the last point of the wave if no /R). Searching backwards is permitted, and exchanges the values of V_LeadingEdgeLoc and V_TrailingEdgeLoc.

A simple automatic peak-finder is implemented in the procedure file:

```
#include <Peak AutoFind>
```

one of the `#include <Multi-peak fitting 1.3>` procedures that provides support for Gaussian, Lorentzian, and Voigt fitting functions. See the "Multi-peak fit" example experiment for details (:Examples:Curve Fitting: folder).

The FindPeak operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

See Also

The **PulseStats** operation, the **FindLevel** operation for details about the /B, /P, /Q, and /R flag values.

FindPointsInPoly

FindPointsInPoly *xWaveName, yWaveName, xPolyWaveName, yPolyWaveName*

The FindPointsInPoly operation determines if points fall within a certain polygon. It can be used to write procedures that operate on a subset of data identified graphically in a graph.

Details

FindPointsInPoly determines which points in *yWaveName* vs *xWaveName* fall within the polygon defined by *yPolyWaveName* vs *xPolyWaveName*.

xWaveName must have the same number of points as *yWaveName* and *xPolyWaveName* must have the same number of points as *yPolyWaveName*.

FindPointsInPoly creates an output wave named W_inPoly with the same number of points as *xWaveName*. FindPointsInPoly indicates whether the point *yWaveName*[p] vs *xWaveName*[p] falls within the polygon by setting `W_inPoly[p]=1` if it is within the polygon, or `W_inPoly[p]=0` if it is not.

FindPointsInPoly uses integer arithmetic with a precision of about 1 part in 1000. This should be good enough for visually determined (hand-drawn) polygons but might not be sufficient for mathematically generated polygons.

The FindPointsInPoly operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

The **GraphWaveDraw** operation.

FindRoots

FindRoots [***flags***] ***funcspec, pWave*** [**,** ***funcspec, pwave*** [**, …**]]

FindRoots /P=*PolyCoefsWave*

The FindRoots operation determines roots or zeros of a specified nonlinear function or system of functions. The function or system of functions must be defined in the form of Igor user procedures.

Using the second form of the command, FindRoots finds all the complex roots of a polynomial with real coefficients. The polynomial coefficients are specified by *PolyCoefsWave*.

Flags for roots of nonlinear functions

/B [= *doBracket*] Specifies bracketing for roots of a single nonlinear function only.

doBracket=0: Skips an initial check of the root bracketing values and the possible search for bracketing values. This means that you must provide good bracketing values via the /L and /H flags. See /L and /H flags for details on bracketing of roots. /B alone is the same as /B=0.

doBracket=1: Uses default root bracketing.

/F=*trustRegion* Sets the expansion factor of the trust region for the search algorithm when finding roots of systems of functions. Smaller numbers will result in a more stable search, although for some functions larger values will allow the search to zero in on a root more rapidly. Default is 1.0; useful values are usually between 0.1 and 100.

/I=*maxIters* Sets the maximum number of iterations in searching for a root to *maxIters*. Default is 100.

/L=*lowBracket*
/H=*highBracket* /L and /H are used only when finding roots of a single nonlinear function. *lowBracket* and *highBracket* are X values that bracket a zero crossing of the function. A root is found between the bracketing values.

If *lowBracket* and *highBracket* are on the same side of zero, it will try to find a minimum or maximum between *lowBracket* and *highBracket*. If it is found, and it is on the other side of zero, Igor will find two roots.

If *lowBracket* and *highBracket* are on the same side of zero, but no suitable extreme point is found between, it will search outward from these values looking for a zero crossing. If it is found, Igor determines one root.

If *lowBracket* and *highBracket* are equal, it adds 1.0 to *highBracket* before looking for a zero crossing.

The default values for *lowBracket* and *highBracket* are zero. Thus, not using either *lowBracket* or *highBracket* is the same as /L=0/H=1.

/Q Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.

/T=*tol* Sets the acceptable accuracy to *tol*. That is, the reported root should be within ±*tol* of the real root.

/X=*xWave*
/X={*x1*, *x2*, …} Sets the starting point for searching for a root of a system of functions. There must be as many X values as functions. The starting point can be specified with a wave having as many points as there are functions, or you can write out a list of X values in braces. If you are finding roots of a single function, use /L and /H instead.

If you specify a wave, this wave is also used to receive the result of the root search.

/Z=*yValue* Finds other solutions, that is, places where f(x) = *yValue*. FindRoots usually finds zeroes — places where f(x) = 0.

Flag for roots of polynomials

/P=*PolyCoefsWave* Specifies a wave containing real polynomial coefficients. With this flag, it finds polynomial roots and does not expect to find user function names on the command line.

The /P flag causes all other flags to be ignored.

Use of this flag is not permitted in a thread-safe function.

Parameters

func specifies the name of a user-defined function.

pwave gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified. It is intended for your private use to pass adjustable constants to your function.

These parameters occur in pairs. For a one-dimensional problem, use a single *func*, *pwave* pair. An N-dimensional problem requires N pairs unless you use the combined function form (see **Combined Format for Systems of Functions**).

Function Format for 1D Nonlinear Functions

Finding roots of a nonlinear function or system of functions requires that you realize the function in the form of an Igor user function of a certain form. In the FindRoots command you then specify the functions with one or more function names paired with parameter wave names. See **Finding Function Roots** on page III-283 for detailed examples.

The functions must have a particular form. If you are finding the roots of a single 1D function, it should look like this:

```
Function myFunc(w,x)
    Wave w
    Variable x

    return f(x)          // an expression …
End
```

Replace "`f(x)`" with an appropriate expression. The FindRoots command might then look like this:

```
FindRoots /L=0 /H=1 myFunc, cw       // cw is a parameter wave for myFunc
```

Function Format for Systems of Multivariate Functions

If you need to find the roots of a system of multidimensional functions, you can use either of two forms. In one form, you provide N functions with N independent variables. You must have a function for each independent variable. For instance, to find the roots of two 2D functions, the functions must have this form:

```
Function myFunc1(w, x1, x2)
    Wave w
    Variable x1, x2

    return f1(x1, x2)       // an expression …
End

Function myFunc2(w, x1, x2)
    Wave w
    Variable x1, x2

    return f2(x1, x2)       // an expression …
End
```

In this case, the FindRoots command might look like this (where `cw1` and `cw2` are parameter waves that must be made before executing FindRoots):

```
FindRoots /X={0,1} myFunc1, cw1, myFunc2, cw2
```

You can also use a wave to pass in the X values. Make sure you have the right number of points in the X wave — it must have N points for a system of N functions.

```
Function myFunc1(w, xW)
    Wave w, xW

    return f1(xW[0], xW[1])        // an expression …
End

Function myFunc2(w, xW)
    Wave w, xW

    return f2(xW[0], xW[1])        // an expression …
End
```

Combined Format for Systems of Functions

For large systems of equations it may get tedious to write a separate function for each equation, and the FindRoots command line will get very long. Instead, you can write it all in one function that returns N Y values through a Y wave. The X values are passed to the function through a wave with N elements. The parameter wave for such a function must have N columns, one column for each equation. The parameters for equation N are stored in column N-1. FindRoots will complain if any of these waves has other than N rows.

Here is an template for such a function:

```
Function myCombinedFunc(w, xW, yW)
    Wave w, xW, yW

    yW[0] = f1(w[0][...], xW[0], xW[1],..., xW[N-1])
    yW[1] = f2(w[1][...], xW[0], xW[1],..., xW[N-1])
```

```
    …
    yW[N-1] = fN(w[N-1][...], xW[0], xW[1],..., xW[N-1])
End
```

When you use this form, you only have one function and parameter wave specification in the FindRoots command:

```
Make/N=(nrows, nequations) paramWave
fill in paramWave with values
Make/N=(number of equations) guessWave
guessWave = {x0, x1, …, xN}
FindRoots /X=guessWave myCombinedFunc, paramWave
```

FindRoots has no idea how many actual equations you have in the function. If it doesn't match the number of rows in your waves, your results will not be what you expect!

Coefficients for Polynomials

To find the roots of a polynomial, you first create a wave with the correct number of points. For a polynomial of degree N, create a wave with N+1 points. For instance, to find roots of a cubic equation you need a four-point wave.

The first point (row zero) of the wave contains the constant coefficient, the second point contains the coefficient for X, the third for X^2, etc.

There is no hard limit on the maximum degree, but note that there are significant numerical problems associated with computations involving high-degree polynomials. Round-off error most likely limits reasonably accurate results to polynomials with degree limited to 20 to 30.

Ultimately, if you are willing to accept very limited accuracy, the numerical problems will result in a failure to converge. In limited testing, we found no failures to converge with polynomials up to at least degree 100. At degree 150, we found occasional failures. At degree 200 the failures were frequent, and at degree 500 we found no successes.

Note that you really can't evaluate a polynomial with such high degree, and we have no idea if the computed roots for a degree-100 polynomial have any practical relationship to the actual roots.

While FindRoots is a thread-safe operation, finding polynomial roots is not. Using FindRoots/P=polyWave in a ThreadSafe function results in a compile error.

Results for Nonlinear Functions and Systems of Functions

The FindRoots operation reports success or failure via the V_flag variable. A nonzero value of V_flag indicates the reason for failure:

`V_flag`	0:	Successful search for a root. Otherwise, the value indicates what went wrong:
	1:	User abort.
	3:	Exceeded maximum allowed iterations
	4:	/T=*tol* was too small. Reported by the root finder for systems of nonlinear functions.
	5:	The search algorithm wasn't making sufficient progress. It may mean that /T=*tol* was set to too low a value, or that the search algorithm has gotten trapped at a false root. Try restarting from a different starting point.
	6:	Unable to bracket a root. Reported when finding roots of single nonlinear functions.
	7:	Fewer roots than expected. Reported by the polynomial root finder. This may indicate that roots were successfully found, but some are doubled. Happens only rarely.
	8:	Decreased degree. Reported by the polynomial root finder. This indicates that one or more of the highest-order coefficients was zero, and a lower degree polynomial was solved.
	9:	Convergence failure or other numerical problem. Reported by the polynomial root finder. This indicates that a numerical problem was detected during the computation. The results are not valid.

The results of finding roots of a single 1D function are put into several variables:

`V_numRoots`	The number of roots found. Either 1 or 2.

V_Root	The root.
V_YatRoot	The Y value of the function at the root. *Always* check this; some discontinuous functions may give an indication of success, but the Y value at the found root isn't even close to zero.
V_Root2	Second root if FindRoots found two roots.
V_YatRoot2	The Y value at the second root.

Results for roots of a system of nonlinear functions are reported in waves:

W_Root	X values of the root of a system of nonlinear functions. If you used /X=*xWave*, the root is reported in your wave instead.
W_YatRoot	The Y values of the functions at the root of a system of nonlinear functions. Only one root is found during a single call to FindRoots.

Roots of a polynomial are reported in a wave:

W_polyRoots	A complex wave containing the roots of a polynomial. The number of roots should be equal to the degree of the polynomial, unless a root is doubled.

See Also

Finding Function Roots on page III-283.

The FindRoots operation uses the Jenkins-Traub algorithm for finding roots of polynomials:

Jenkins, M.A., Algorithm 493, Zeros of a Real Polynomial, *ACM Transactions on Mathematical Software*, *1*, 178-189, 1975. Used by permission of ACM (1998).

FindSequence

FindSequence [***flags***] ***srcWave***

The FindSequence operation finds the location of the specified sequence starting the search from the specified start point. The result of the search stored in V_value is the index of the entry in the wave where the first value is found or -1 if the sequence was not found.

Flags

/I=*wave*	Specifies an integer sequence wave for integer search.
/M=*val*	If there are repeating entries in the match sequence, *val* is a tolerance value that specifies the maximum difference between the number of repeats. So, for example, if the match sequence is aaabbccc and the *srcWave* contains a sequence aabbcc then the sequence will not be considered a match if *val*=0 but will be considered a match if *val*=1.
/S=*start*	Sets starting point of the search. If /S is not specified, start is 0.
/T=*tolerance*	Defines the tolerance (value ± *tolerance* will be accepted) when comparing floating point numbers.
/U=*uValue*	Specifies the match sequence wave in case of unsigned long range.
/V=*rValue*	Specifies the match sequence wave in the case of single/double precision numbers.
/Z	No error reporting.

Details

If the match sequence is specified via the /V flag, it is considered to be a floating point wave (i.e., single or double precision) in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the /T flag, the default value 1.0^{-7}.

If the match sequence is specified via the /I flag, the sequence is assumed to be an integer wave (this includes both signed and unsigned char, signed and unsigned short as well as long). In this case *srcWave* must also be of integer type and the operation searches for the sequence based on exact equality between the match sequence and entries in the wave as signed long integers.

If the match sequence is unsigned long wave use the /U flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

```
col=floor(V_value/rowsInWave)
row=V_value-col*rowsInWave
```

See Also
The **FindValue** operation.

FindValue

FindValue [***flags***] ***srcWave***
FindValue [***flags***] ***txtWave***

This operation finds the location of the specified value starting the search from the specified start point. The result of the search stored in V_value is the index of the entry in the wave where the value is found or -1 if not found.

Flags

/I=*ivalue* Specifies an integer value for integer search.

/S=*start* Sets start of search in the wave. If /S is not specified, start is set to 0.

/T=*tolerance* Use this flag when comparing floating point numbers to define a non-negative tolerance such that the specified value ± *tolerance* will be accepted.

/TEXT=*templateString*
Specifies a template string that will be searched for in *txtWave*.

/TXOP=*txOptions* Specifies the search options using a combination of binary values

txOptions	Search Type
1	Case sensitive
2	Whole word
4	Whole wave element

/U=*uValue* Specifies the match value in case of unsigned long range.

/V=*rValue* Specifies the match value in the case of single/double precision numbers.

/Z No error reporting.

Details

If the match value is specified via the /V flag, it is considered to be a floating point value in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the /T flag, the value 10^{-7} is used.

If the match value is specified via the /I flag, the value is assumed to be an integer. In this case *srcWave* must be of integer type and the operation searches for the value based on exact equality between the match value and entries in the wave as signed long integers.

If the match value is unsigned long use the /U flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

```
col=floor(V_value/rowsInWave)
row=V_value-col*rowsInWave
```

When searching for text in a text wave the operation creates the variable V_value as above but it also creates the variable V_startPos to specify the position of *templateString* from the start of the particular wave element.

See Also
The **FindSequence**, **FindLevel** and **FindLevels** operations.

FitFunc

FitFunc

Marks a user function as a user-defined curve fit function. By default, only functions marked with this keyword are displayed in the Function menu in the Curve Fit dialog.

If you wish other functions to be displayed in the Function menu, you can select the checkbox labelled "Show old-style functions (missing FitFunc keyword)".

See Also
User-Defined Fitting Function: Detailed Description on page III-217.

floor

floor(*num*)
The floor function returns the closest integer less than or equal to *num*.

See Also
The **round**, **ceil**, and **trunc** functions.

FontList

FontList(*separatorStr* [, *options*])
The FontList function returns a list of the installed fonts, separated by the characters in *separatorStr*.

Parameters
A maximum of 10 characters from *separatorStr* are appended to each font name as the output string is generated. *separatorStr* is usually ";".

Use *options* to limit the returned font list according to font type. It is restricted to returning only scalable fonts (TrueType, PostScript, or OpenType), which you can do with *options* = 1.

To get a list of nonscalable fonts (bitmap or raster), use:

```
String bitmapFontList = RemoveFromList(FontList(";",1), FontList(";"))
```

(Most Mac OS X fonts are scalable, so bitmapFontList may be empty.)

Examples

```
Function SetFont(fontName)
    String fontName
    Prompt fontName,"font name:",popup,FontList(";")+"default;"
    DoPrompt "Pick a Font", fontName

    Print fontName

    Variable type= WinType("")                  // target window type
    String windowName= WinName(0,127)
    if((type==1) || (type==3) || (type==7))     // graph, panel, layout
        Print "Setting drawing font for "+windowName
        Execute "SetDrawEnv fname=\""+fontName+"\""
    else
        if( type == 5 )                         // notebook
            Print "Setting font for selection in "+windowName
            Notebook $windowName font=fontName
        endif
    endif
End
```

Execute on the command line:

```
SetFont("")
```

See Also
The **FontSizeStringWidth**, **FontSizeHeight**, and **WinType** functions, and the **Execute**, **SetDrawEnv**, and **Notebook** Operations.

FontSizeHeight

FontSizeHeight(*fontNameStr, fontSize, fontstyle* [,*appearanceStr*])
The FontSizeHeight function returns the line height in pixels of any string when rendered with the named font and the given font style and size.

Parameters
fontNameStr is the name of the font, such as `"Helvetica"`.

fontSize is the size (height) of the font in pixels.

fontStyle is text style (bold, italic, etc.). Use 0 for plain text.

Details

The returned height is the sum of the font's ascent and descent heights. Variations in *fontStyle* and typeface design cause the actual font height to be different than *fontSize* would indicate. (Typically a font "height" refers to only the ascent height, so the total height will be slightly larger to accommodate letters that descend below the baseline, such as g, p, q, and y).

FontSize is in pixels. To obtain the height of a font specified in points, use the **ScreenResolution** function and the conversion factor of 72 points per inch (see Examples).

If the named font is not installed, FontSizeHeight returns NaN.

FontSizeHeight understands "default" to mean the current experiment's default font.

fontStyle is a binary coded integer with each bit controlling one aspect of the text style as follows:

bit 0:	Bold.
bit 1:	Italic.
bit 2:	Underline.
bit 3:	Outline (*Macintosh only*).
bit 4:	Shadow (*Macintosh only*).

To set bit 0 and bit 2 (bold, underline), use $2^0+2^2 = 1+4 = 5$ for *fontStyle*. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

The optional *appearanceStr* parameter has no effect on Windows.

On Macintosh, the *appearanceStr* parameter is used for determining the height of a string drawn by a control. Set *appearanceStr* to "native" if you are measuring the height of a string drawn by a "native GUI" control or to "os9" if not.

Set *appearanceStr* to "default" to use the appearance set by the user in the Miscellaneous Settings dialog. "os9" is the default value.

Usually you will want to set *appearanceStr* to the S_Value output of **DefaultGUIControls**/W=winName when determining the height of a string drawn by a control.

Examples

```
Variable pixels= 12 * ScreenResolution/72         // convert 12 points to pixels
Variable pixelHeight= FontSizeHeight("Helvetica",pixels,0)
Print "Height in points= ", pixelHeight * 72/ScreenResolution
```

```
Function FontIsInstalled(fontName)
   String fontName
   if( numtype(FontSizeHeight(fontName,10,0)) == 2 )
      return 0            // NaN returned, font not installed
   else
      return 1
   endif
End
```

See Also

The **FontList**, **FontSizeStringWidth**, **numtype**, **ScreenResolution**, and **DefaultGUIControls** functions.

FontSizeStringWidth

FontSizeStringWidth(*fontNameStr, fontSize, fontstyle, theStr* [,*appearanceStr*])

The FontSizeStringWidth function returns the width of *theStr* in pixels, when rendered with the named font and the given font style and size.

Parameters

fontNameStr is the name of the font, such as `"Helvetica"`.

fontSize is the size (height) of the font in pixels.

fontStyle is text style (bold, italic, etc.). Use 0 for plain text.

theStr is the string whose width is being measured.

The optional *appearanceStr* parameter has no effect on Windows.

On Macintosh, the *appearanceStr* parameter is used for determining the width of a string drawn by a control. Set *appearanceStr* to "native" if you are measuring the width of a string drawn by a "native GUI" control or to "os9" if not.

Set *appearanceStr* to "default" to use the appearance set by the user in the Miscellaneous Settings dialog. "os9" is the default value.

Usually you will want to set *appearanceStr* to the S_Value output of **DefaultGUIControls**/W=winName when determining the width of a string drawn by a control.

Details

If the named font is not installed, FontSizeStringWidth returns NaN.

FontSizeStringWidth understands "default" to mean the current experiment's default font.

FontSize is in pixels. To obtain the width of a font specified in points, use the **ScreenResolution** function and the conversion factor of 72 points per inch (see Examples).

fontStyle is a binary coded integer with each bit controlling one aspect of the text style as follows:

bit 0:	Bold.
bit 1:	Italic.
bit 2:	Underline.
bit 3:	Outline (*Macintosh only*).
bit 4:	Shadow (*Macintosh only*).

To set bit 0 and bit 2 (bold, underline), use $2^0+2^2 = 1+4 = 5$ for *fontStyle*. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

Example 1

```
Variable fsPix= 10 * ScreenResolution/72          // 10 point text in pixels
String text= "How long is this text?"
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text)
Print "width in inches= ", WidthPix / ScreenResolution
```

Example 2

```
Variable fsPix= 13 * ScreenResolution/72          // 13 point text in pixels
String text= "text for a control"
DefaultGUIControls/W=Panel0                       // Sets S_Value
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text,S_Value)
Print "width in points= ", WidthPix / ScreenResolution * 72
```

See Also

The **FontList**, **FontSizeHeight**, **ScreenResolution** and **DefaultGUIControls** functions.

for-endfor

```
for(<initialize>;<exit test>;<update>)
   <loop body>
endfor
```

A for-endfor loop executes *loop body* code until *exit test* evaluates as FALSE, zero, or until a break statement is executed within the body code. When the loop starts, the *initialize* expressions are evaluated once. For each iteration, the *exit test* is evaluated at the beginning, and the *update* expressions are evaluated at the end.

See Also

For Loop on page IV-37 and **break** for more usage details.

FPClustering

```
FPClustering [flags] srcWave
```

The FPClustering operation performs cluster analysis using the farthest-point clustering algorithm. The input for the operation *srcWave* defines M points in N-dimensional space. Outputs are the waves W_FPCenterIndex and W_FPClusterIndex.

Flags

/CAC	Computes all the clusters specified by /MAXC.
/CM	Computes the center of mass for each cluster. The results are stored in the wave M_clustersCM in the current data folder. Each row corresponds to a single cluster with columns providing the respective dimensional components.
/INCD	Computes the inter-cluster distances. The result is stored in the current data folder in the wave M_InterClusterDistance, a 2D wave in which the [*i*][*j*] element contains the distance between cluster *i* and cluster *j*.
/MAXC=*nClusters*	Terminates the calculation when the number of clusters reaches the specified value. Note that this termination condition is sufficient but not necessary, i.e., the operation can terminate earlier if the farthest distance of an element from a hub is less than the average distance.
/MAXR=*maxRad*	Terminates the calculation when the maximum distance is less than or equal to *maxRad*.
/NOR	Normalizes the data on a column by column basis. The normalization makes each columns of the input span the range [0,1] so that even when *srcWave* contains columns that may be different by several orders of magnitude, the algorithm is not biased by a larger implied cartesian distance.
/Q	Don't print information to the history window.
/SHUB=*sHub*	Specifies the row which is used as a starting hub number. By default the operation uses the first row in *srcWave*.
/Z	No error reporting.

Details

The input for FPClustering is a 2D wave *srcWave* which consists of M rows by N columns where each row represents a point in N-dimensional space. *srcWave* can contain only finite real numbers and must be of type SP or DP. The operation computes the clustering and produces the wave W_FPCenterIndex which contains the centers or "hubs" of the clusters. The hubs are specified by the zero-based row number in *srcWave* which contains the cluster center. In addition, the operation creates the wave W_FPClusterIndex where each entry maps the corresponding input point to a cluster index. By default, the operation continues to add clusters as long as the largest possible distance is greater than the average intercluster distance. You can also stop the processing when the operation has formed a specified number of clusters (see /MAXC).

The variable V_max contains the maximum distance between any element and its cluster hub.

It is possible that in some circumstances you can get slightly different clustering depending on your starting point. The default starting hub is row zero of *srcWave* but you can use the /SHUB flag to specify a different starting point.

FPClustering computes the Cartesian distance between points. As a result, if the scale of any dimension is significantly larger than other dimensions it might bias the clustering towards that dimension. To avoid this situation you can use the /NOR flag which normalizes each column to the range [0,1] and hence equalizes the weight of each dimension in the clustering process.

The **KMeans** operation.

References

Gonzalez, T., Clustering to minimize the maximum intercluster distance, *Theoretical Computer Science*, *38*, 293-306, 1985.

fprintf

fprintf *refNum*, *formatStr* [, *parameter*]…

The fprintf operation prints formatted output to a text file.

Parameters

refNum is a file reference number from the **Open** operation used to open the file.

formatStr is the format string, as used by the **printf** operation.

parameter varies depending on *formatStr*.

Details

If *refNum* is 1, fprintf will print to the history area instead of to a file, as if you used printf instead of fprintf. This useful for debugging purposes.

A zero value of *refNum* is used in conjunction with Program-to-Program Communication (PPC), Apple events (*Macintosh*) or DDE (*Windows*). Data that would normally be written to a file is appended to the PPC, Apple event or DDE result packet.

The fprintf operation supports numeric (real only) and string fields from structures. All other field types will cause a compile error.

See Also

The **printf** operation for complete format and parameter descriptions. The **Open** operation and **Creating Formatted Text** on page IV-230.

FReadLine

FReadLine [**/N/T**] ***refNum, stringVarName***

The FReadLine operation reads bytes from a file into the named string variable. The read starts at the current file position and continues until a terminator character is read, the end of the file is reached, or the maximum number of characters is read.

Parameters

refNum is a file reference number from the **Open** operation used to create the file.

Flags

/N=*n*	Specifies the maximum number of characters to read.
/T=*termcharStr*	Specifies the terminator character.
	`/T=(num2char(13))` specifies carriage return (CR, ASCII code 13).
	`/T=(num2char(10))` specifies linefeed (LF, ASCII code 10).
	`/T=";"` specifies the terminator as a semicolon.
	`/T=""` specifies the terminator as null (ASCII code 0).
	See **Details** for default behavior regarding the terminator.

Details

If /N is omitted, there is no maximum number of characters to read. When reading lines of text from a normal text file, you will not need to use /N. It may be of use in specialized cases, such as reading text embedded in a binary file.

If /T is omitted, FReadLine will terminate on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.) FReadLine reads whichever of these appears in the file, terminates the read, and returns just a CR in the output string. This default behavior transparently handles files that use CR, LF, CRLF, or LFCR as the terminator and will be suitable for most cases.

If you use the /T flag, then FReadLine will terminate on the specified character only and will return the specified character in the output string.

Once you have read all of the characters in the file, FReadLine will return zero characters via *stringVarName*. The example below illustrates testing for this.

Example

```
Function PrintAllLinesInFile()
    Variable refNum
    Open/R refNum as ""           // Display dialog
    if (refNum == 0)
        return -1                 // User canceled
    endif

    Variable lineNumber, len
    String buffer
    lineNumber = 0
    do
        FReadLine refNum, buffer
        len = strlen(buffer)
        if (len == 0)
```

```
            break                   // No more lines to be read
        endif
        Printf "Line number %d: %s", lineNumber, buffer
        if (CmpStr(buffer[len-1],"\r") != 0)       // Last line has no CR ?
            Printf "\r"
        endif
    lineNumber += 1
    while (1)

    Close refNum
    return 0
End
```

The **fresnelCos** and **fresnelCS** functions.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

FSetPos

FSetPos *refNum, filePos*

The FSetPos operation attempts to set the current file position to the given position.

Parameters

refNum is a file reference number obtained from the **Open** operation when the file was opened.

filePos is the desired position of the file in bytes from the start of the file.

Details

FSetPos generates an error if *filePos* is greater than the number of bytes in the file. You can ascertain this limit with the **FStatus** operation.

When a file that is open for writing is closed, any bytes past the end of the current file position are deleted by the operating system. Therefore, if you use FSetPos, make sure to set the current file position properly before closing the file.

As of Igor Pro 6.1, FSetPos supports very big files theoretically up to about 4.5E15 bytes in length.

See Also

The **Open** and **FStatus** operations.

FStatus

FStatus *refNum*

The FStatus operation provides file status information for a file.

Parameters

refNum is a file reference number obtained from the **Open** operation.

Details

As of Igor Pro 6.1, FStatus supports very big files theoretically up to about 4.5E15 bytes in length.

FStatus sets the following variables:

V_flag	Nonzero (true) if *refNum* is valid, in which case FStatus sets the other variables as well.
V_filePos	Current file position for the file in bytes from the start.
V_logEOF	Total number of bytes in the file.
S_fileName	Name of the file.
S_path	Path from the volume to the folder containing the file. For example, "hd:Folder1:Folder2:". This is suitable for use as an input to the **NewPath** operation. Note that on the Windows operating system Igor uses a colon between folders instead of the Windows-standard backslash to avoid confusion with Igor's use of backslash to start an escape sequence (see **Escape Characters in Strings** on page IV-13).
S_info	Keyword-packed information string.

The keyword-packed information string for S_info consists of a sequence of sections with the following form: *keyword*:*value*; You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions.

Here are the keywords for S_info:

Keyword	Type	Meaning
PATH	string	Name of the symbolic path in which the file is located. This will be empty if there is no such symbolic path.
WRITEABLE	number	1 if file can be written to, 0 if not.

See Also

The **Open** operation.

FTPCreateDirectory

FTPCreateDirectory [***flags***] ***urlStr***

The FTPCreateDirectory operation creates a directory on an FTP server on the Internet.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-244.

FTPCreateDirectory sets V_flag to zero if the operation succeeds or to a non-zero error code if it fails.

If the directory specified by *urlStr* already exists on the server, the server contents are not touched and V_flag is set to -1. This is not treated as an error.

Parameters

urlStr specifies the directory to create. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/test/newDirectory"). For example:

```
"ftp://ftp.wavemetrics.com/test/newDirectory"
```

urlStr must always end with a directory name, and must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test/newDirectory
```

If you do not specify that the path in *urlStr* is absolute, it is interpreted as relative to the FTP user's base directory. Since pub is the base directory for an anonymous user at wavemetrics.com, these URLs reference the same directory for an anonymous user:

```
ftp://ftp.wavemetrics.com//pub/test/newDirectory  // Absolute path
ftp://ftp.wavemetrics.com/test/newDirectory       // Relative to base directory
```

Special characters, such as punctuation, that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-239 for additional information.

Flags

/N=*portNumber*
: Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, the default will be correct so you won't need to use the /N flag.

/U=*userNameStr*
: Specifies the user name to be used when logging in to the FTP server. If /U is omitted or if *userNameStr* is "", the login is done as an anonymous user. Use /U if you have an account on the FTP server.

/V=*diagnosticMode*
: Determines what kind of diagnostic messages FTPCreateDirectory will display in the history area. *diagnosticMode* is a bitwise parameter, with the bits defined as follows:

  Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.

  Bit 1: Show errors. This displays additional information when errors occur.

  Bit 2: Show status. This displays commands sent to the server and the server's response.

  The default value for *diagnosticMode* is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.

  See **FTP Troubleshooting** on page IV-247 for other troubleshooting tips.

/W=*passwordStr*
: Specifies the password to be used when logging in to the FTP server. Use /W if you have an account on the FTP server.

  If /W is omitted, the login is done using a default password that will work with most anonymous FTP servers.

  Note: See **Safe Handling of Passwords** on page IV-241 for information on handling sensitive passwords.

/Z
: Errors are not fatal. Will not abort procedure execution if an error occurs.

  Your procedure can inspect the V_flag variable to see if the transfer succeeded. V_flag will be zero if it succeeded, -1 if the specified directory already exists, or another nonzero value if an error occurred.

Examples

```
// Create a directory.
String url = "ftp://ftp.wavemetrics.com/pub/test/newDirectory"
FTPCreateDirectory url
```

See Also

File Transfer Protocol (FTP) on page IV-244.

FTPDelete, **FTPDownload**, **FTPUpload**, **URLEncode**

FTPDelete

FTPDelete [***flags***] ***urlStr***

The FTPDelete operation deletes a file or a directory from an FTP server on the Internet.

Warning: If you delete a directory on an FTP server, all contents of that directory and any subdirectories are also deleted.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-244.

FTPDelete sets V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if an FTP error occurs.

Parameters

urlStr specifies the file or directory to delete. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/test/TestFile1.txt"

urlStr must always end with a file name if you are deleting a file or with a directory name if you are deleting a directory. In the case of a directory, *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is absolute, it is interpreted as relative to the FTP user's base directory. Since pub is the base directory for an anonymous user at wavemetrics.com, these URLs reference the same directory for an anonymous user:

```
ftp://ftp.wavemetrics.com//pub/test
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-239 for additional information

Flags

/D — Deletes a complete directory and all its contents. Omit /D if you are deleting a file.

/N=*portNumber* — Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, the default will be correct so you won't need to use the /N flag.

/U=*userNameStr* — Specifies the user name to be used when logging in to the FTP server. If /U is omitted or if userNameStr is "", the login is done as an anonymous user. Use /U if you have an account on the FTP server.

/V=*diagnosticMode* — Determines what kind of diagnostic messages FTPCreateDirectory will display in the history area. *diagnosticMode* is a bitwise parameter, with the bits defined as follows:

Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.

Bit 1: Show errors. This displays additional information when errors occur.

Bit 2: Show status. This displays commands sent to the server and the server's response.

The default value for *diagnosticMode* is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.

See **FTP Troubleshooting** on page IV-247 for other troubleshooting tips.

/W=*passwordStr* — Specifies the password to be used when logging in to the FTP server. Use /W if you have an account on the FTP server.

If /W is omitted, the login is done using a default password that will work with most anonymous FTP servers.

Note: See **Safe Handling of Passwords** on page IV-241 for information on handling sensitive passwords.

/Z — Errors are not fatal. Will not abort procedure execution if an error occurs.

Your procedure can inspect the V_flag variable to see if the transfer succeeded. V_flag will be zero if it succeeded, or a nonzero value if an error occurred.

Examples

```
// Delete a file.
String url = "ftp://ftp.wavemetrics.com/test/TestFile1.txt"
FTPDelete url

// Delete a directory.
String url = "ftp://ftp.wavemetrics.com/test/TestDir1"
FTPDelete/D url
```

File Transfer Protocol (FTP) on page IV-244.

FTPCreateDirectory, **FTPDownload**, **FTPUpload**, **URLEncode**

FTPDownload

FTPDownload [*flags*] *urlStr*, *localPathStr*

The FTPDownload operation downloads a file or a directory from an FTP server on the Internet.

Warning: When you download a file or directory using the path and name of a file or directory that already exists on your local hard disk, all previous contents of the local file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-244.

FTPDownload sets a variable named V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if a FTP error occurs.

If the operation succeeds, FTPDownload sets a string named S_Filename to the full file path of the downloaded file or, if the /D flag was used, the full path to the base directory that was downloaded. This is useful in conjunction with the /I flag.

If the operation fails, S_Filename is set to "".

Parameters

urlStr specifies the file or directory to download. It consists of a naming scheme (always `"ftp://"`), a computer name (e.g., `"ftp.wavemetrics.com"` or `"38.170.234.2"`), and a path (e.g., `"/Test/TestFile1.txt"`). For example: `"ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"`.

urlStr must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is an absolute path, it is interpreted as a path relative to the FTP user's base directory. Since pub is the base directory for an anonymous user, this URL references the same directory:

```
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-239 for additional information.

localPathStr and *pathName* specify the name to use for the file or directory that will be created on your hard disk. If you use a full or partial path for *localPathStr*, see **Path Separators** on page III-398 for details on forming the path.

localPathStr must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, *localPathStr* must not end with a colon or backslash.

FTPDownload displays a dialog through which you can identify the local file or directory in the following cases:

1. You have used the /I (interactive) flag.
2. You did not completely specify the location of the local file or directory via *pathName* and *localPathStr*.

3. There is an error in *localPathStr*. This can be either a syntactical error or a reference to a nonexistent file or directory.
4. The specified local file or directory exists and you have not used the /O (overwrite) flag.

See **Examples** for examples of constructing a URL and local path.

Flags

/D — Downloads a complete directory. Omit it if you are downloading a file.

/I — Interactive mode which will prompt you to specify the name and location of the file or directory to be created on the local hard disk.

/M=*messageStr* — Specifies the prompt message used by the dialog in which you specify the name and location of the file or directory to be created.

/N=*portNumber* — Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won't need to use the /N flag.

/O[=*mode*] — Controls whether a local file or directory whose name is in conflict with the file or directory being downloaded is overwritten without prompting the user.

- 0: Prompts the user to allow the overwrite. This is the default behavior if /O is omitted.
- 1: Overwrites without prompting the user. If the /D flag is also used, all contents of the destination directory are deleted if it already exists. /O=1 is the same as /O.
- 2: Merges files and subdirectories downloaded with the contents of the destination directory. Unlike /O=1, the contents of the destination directory are not deleted, however files and directories downloaded from the server will overwrite existing files and directories of the same name. When downloading a file this mode is accepted but has the same effect as /O=1.

/P=*pathName* — Contributes to the specification of the file or directory to be created on your hard disk. *pathName* is the name of an existing symbolic path. See **Examples**.

/S=*showProgress* — Displays a progress dialog.

- 0: No progress dialog.
- 1: Show a progress dialog (default).

/T=*transferType* — Transfers in image binary mode.

- 0: Image (binary) transfer (default).
- 1: ASCII transfer.

See **FTP Transfer Types** on page IV-247 for more discussion.

/U=*userNameStr* — Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if *userNameStr* is `""`, you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.

/V=*diagnosticMode* — Determines what kind of diagnostic messages FTPDownload will display in the history area. *diagnosticMode* is a bitwise parameter, with the bits defined as follows:

- Bit 0: Show basic diagnostics. Currently, this displays the URL and the local path in the history.
- Bit 1: Show errors. This displays additional information when errors occur.
- Bit 2: Show status. This displays commands sent to the server and the server's response.

The default value for this parameter is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.

See **FTP Troubleshooting** on page IV-247 for other troubleshooting tips.

/W=*passwordStr* — Specifies the password to be used when logging in to the FTP server. Use this flag if you have an account on the FTP server.

If this flag is omitted, "nopassword" will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the /W="<your email address>" flag.

If /W is omitted, the login is done using a default password that will work with most anonymous FTP servers.

Note: See **Safe Handling of Passwords** on page IV-241 for information on handling sensitive passwords.

/Z — Errors are not fatal. Will not abort procedure execution if an error occurs.

Your procedure can inspect the V_flag variable to see if the transfer succeeded. V_flag will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.

Examples

Download a file using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test Folder:TestFile1.txt"
FTPDownload url, localPath
```

Download a file using a local symbolic path and file name:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String pathName = "Igor"      // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPDownload/P=$pathName url, fileName
```

Download a directory using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPDownload/D url, localPath
```

See Also

File Transfer Protocol (FTP) on page IV-244.

FTPCreateDirectory, **FTPDelete**, **FTPUpload**, **URLEncode**, **FetchURL**.

FTPUpload

FTPUpload [***flags***] ***urlStr, localPathStr***

The FTPUpload operation uploads a file or a directory to an FTP server on the Internet.

Warning: When you upload a file or directory to an FTP server, all previous contents of the server file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-244.

FTPUpload sets a variable named V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if a FTP error occurs.

If the operation succeeds, FTPUpload sets a string named S_Filename to the full file path of the uploaded file or, if the /D flag was used, to the full path to the base directory that was uploaded. This is useful in conjunction with the /I flag.

If the operation fails, S_Filename is set to "".

Parameters

urlStr specifies the file or directory to create. It consists of a naming scheme (always `"ftp://"`), a computer name (e.g., `"ftp.wavemetrics.com"` or `"38.170.234.2"`), and a path (e.g., `"/Test/TestFile1.txt"`). For example: `"ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"`.

urlStr must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory, in which case *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is an absolute path, it is interpreted as a path relative to the FTP user's base directory. Since pub is the base directory for an anonymous user, this URL references the same directory:

```
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-239 for additional information.

localPathStr and *pathName* specify the name and location on your hard disk of the local file to be uploaded. If you use a full or partial path for *localPathStr*, see **Path Separators** on page III-398 for details on forming the path.

localPathStr must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory. In the case of a directory, *localPathStr* must not end with a colon or backslash.

FTPUpload displays a dialog that you can use to identify the file or directory to be uploaded in the following cases:

1. You used the /I (interactive) flag.
2. You did not completely specify the location of the file or folder to be uploaded via *pathName* and *localPathStr*.
3. There is an error in *localPathStr*. This can be either a syntactical error or a reference to a nonexistent directory.

See **Examples** for examples of constructing a URL and local path.

Flags

/D — Uploads a complete directory. Omit it if you are uploading a file.

/I — Interactive mode which displays a dialog for choosing the local file or directory to be uploaded.

/M=*messageStr* — Specifies the prompt message used by the dialog in which you choose the local file or directory to be uploaded.

/N=*portNumber* — Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won't need to use the /N flag.

/O[=*mode*] — Overwrite. FTPUpload *always* overwrites the specified server file or directory, whether /O is used or not.

If /O=2 is *not* used, all files and subdirectories in the destination directory on the server are first deleted and then the local files and directories are uploaded to the server.

If /O=2 *is* used, the existing contents the contents of the local source directory are merged into the remote directory instead of completely overwriting it.

/P=*pathName* — Contributes to the specification of the file or directory to be uploaded. *pathName* is the name of an existing symbolic path. See **Examples**.

/S=*showProgress* — Displays a progress dialog.

0: No progress dialog.

1: Shows a progress dialog (default).

/T=*transferType* — Transfers in image binary mode.

0: Image (binary) transfer (default).

1: ASCII transfer.

See **FTP Transfer Types** on page IV-247 for more discussion.

/U=*userNameStr* — Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if *userNameStr* is `""`, you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.

/V=*diagnosticMode* — Determines what kind of diagnostic messages FTPUpload will display in the history area. *diagnosticMode* is a bitwise parameter, with the bits defined as follows:

Bit 0: Show basic diagnostics. Currently, this displays the URL and the local path in the history.

Bit 1: Show errors. This displays additional information when errors occur.

Bit 2: Show status. This displays status information returned by the operating system to FTPUpload.

The default value for this parameter is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.

See **FTP Troubleshooting** on page IV-247 for other troubleshooting tips.

/W=*passwordStr* Specifies the password used when logging in to the FTP server. Use this flag if you have an account on the FTP server.

If this flag is omitted, "nopassword" will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the /W="<your email address>" flag.

If /W is omitted, the login is done using a default password that will work with most anonymous FTP servers.

Note: See **Safe Handling of Passwords** on page IV-241 for information on handling sensitive passwords.

/Z Errors are not fatal. Will not abort procedure execution if an error occurs.

Your procedure can inspect the V_flag variable to see if the transfer succeeded. V_flag will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.

Examples

Upload a file using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test Folder:TestFile1.txt"
FTPUpload url, localPath
```

Upload a file using a local symbolic path and file name:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String pathName = "Igor"      // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPUpload/P=$pathName url, fileName
```

Upload a directory using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPUpload/D url, localPath
```

File Transfer Protocol (FTP) on page IV-244.

FTPCreateDirectory, **FTPDelete**, **FTPDownload**, **URLEncode**.

FuncFit

FuncFit [***flags***] ***fitFuncName, cwaveName, waveName*** [***flag parameters***]

FuncFit [***flags***] {***fitFuncSpec***}, ***waveName*** [***flag parameters***]

The FuncFit operation performs a curve fit to a user defined function, or to a sum of fit functions using the second form (see **Fitting Sums of Fit Functions** on page V-195). Fitting can be done using any method that can be selected using the /ODR flag (see **CurveFit** for details).

FuncFit operation parameters are grouped in the following categories: flags, parameters (*fitFuncName*, *cwaveName*, *waveName* or {*fitFuncSpec* }, *waveName*), and flag parameters. The sections below correspond to these categories. Note that flags must precede the *fitFuncName* or `fitFuncSpec` and flag parameters must follow *waveName*.

Flags

See **CurveFit** for all available flags.

Parameters

fitFuncName The user-defined function to fit to, which can be a function taking multiple independent variables (see also **FuncFitMD**). Multivariate fitting with FuncFit *requires* /X=*xwaveSpec*.

cwaveName Wave containing the fitting coefficients.

waveName The wave containing the dependent variable data to be fit to the specified function. For functions of just one independent variable, the dependent variable data is often referred to as "Y data". You can fit to a subrange of the wave by supplying (*startX*,*endX*) or [*startP*,*endP*] after the wave name. See **Wave Subrange Details** below for more information on subranges of waves in curve fitting.

fitFuncSpec List of fit functions and coefficient waves, with some optional information. Using this format fits a model consisting of the sum of the listed fit functions. Intended for fitting multiple peaks, but probably useful for other applications as well. See **Fitting Sums of Fit Functions** on page V-195.

Flag Parameters

These flag parameters must follow *waveName*.

/*E=ewaveName* A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave.

/STRC=*structureInstance*
Used only with **Structure Fit Functions** on page III-226. When using a structure fit function, you must specify an instance of the structure to FuncFit. This will be an instance that has been initialized by a user-defined function that you write in order to invoke FuncFit.

/*X=xwaveSpec* An optional wave containing X values for each of the input data values. If the fitting function has more than one independent variable, *xwaveSpec* is required and must be either a 2D wave with a column for each independent variable, or a list of waves, one for each independent variable. A list must be in braces: /X={*xwave0*, *xwave1*,…}. There must be exactly one column or wave for each independent variable in the fitting function.

/NWOK Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to FuncFit is normally treated as an error. By using /NWOK, you are telling FuncFit that a null wave reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls FuncFit with optional waves.

The waves affected are the X wave or waves (/X), weight wave (/W), epsilon wave (/E) and mask wave (/M). The destination wave (/D=wave) and residual wave (/R=wave) are also affected, but the situation is more complicated because of the dual use of /D and /R to mean "do autodestination" and "do autoresidual". See /AR and /AD.

If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.

Note: To work properly this flag must be the last one in the command.

Other parameters are used as for the **CurveFit** operation, with some exceptions for multivariate fits.

Details for Multivariate Fits

The dependent variable data wave, *waveName*, must be a 1D wave even for multivariate fits. For fits to data in a multidimensional wave, see **FuncFitMD**.

For multivariate fits, the auto-residual (/R with no wave specified) is calculated and appended to the top graph if the dependent variable data wave is graphed in the top graph as a simple 1D trace. Auto residuals are calculated but not displayed if the data are displayed as a contour plot.

The autodest wave (/D with no wave specified) for multivariate fits has the same number of points as the data wave, with a model value calculated at the X values contained in the wave or waves specified with /*X=xwaveSpec*.

Confidence bands are not supported for multivariate fits.

Wave Subrange Details

Almost any wave you specify to FuncFit can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command (see **Subrange Display Syntax** on page II-288 for details). See **Wave Subrange Details** on page V-91 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for CurveFit apply to FuncFit as well.

In addition to the waves discussed in the CurveFit documentation, it is possible to use subranges when specifying the coefficient wave and the epsilon wave. Since the coefficient wave and epsilon wave must have the same number of points, it might make sense to make them two columns from a single multicolumn wave. For instance, here is an example in which the first column is used as the coefficient wave, the second is used as the epsilon wave, and the third is used to save a copy of the initial guesses for future reference:

```
Make/D/N=(5, 3) myCoefs
myCoefs[][0] = {1,2,3,4,5}              // hypothetical initial guess
```

```
myCoefs[][1] = 1e-6                        // reasonable epsilon values
myCoefs[][2] = myCoefs[p][0]               // save copy of initial guess
FuncFit myFitFunc, myCoefs[][0] myData /E=myCoefs[][1] …
```

You might have a fit function that uses a subset of the coefficients that are used by another. It might be useful to use a single wave for both. Here is an example in which a function that takes four coefficients is used to fit a subset of the coefficients, and then that solution is used as the initial guess for a function that takes six coefficients:

```
Make/D/N=6 Coefs6={1,2,3,4,5,6}
FuncFit Fit4Coefs, Coefs6[0,3] fitfunc4Coefs …
FuncFit Fit6Coefs, Coefs6 ...
```

Naturally, the two fit functions must be worked out carefully to allow this.

Fitting Sums of Fit Functions

If Igor encounters a left brace at the beginning of the fit function name, it expects a list of fit functions to be summed during the fit. This is useful for, for instance, fitting several peaks in a data set to a sum of peak functions.

The fit function specification includes at least the name of the fitting function and an associated coefficient wave. A sum of fit functions requires multiple coefficient waves, one for each fit function. Any coefficient wave-related options must be specified in the fit function specification via keyword-value pairs.

The syntax of the sum-of-fit-functions specification is as follows:

{{*func1, coef1, keyword=value*},{*func2, coef2, keyword=value*}, …}

or

{*string=fitSpecStr*}

Within outer braces, each fit function specification is enclosed within inner braces. You can use one or more fit function specifications, with no intrinsic limit on the number of fit functions.

The second format is available to overcome limitations on the length of a command line in Igor. This format is just like the first, but everything inside the outer braces is contained in a string expression (which may be just a single string variable).

You can use any fit function that can be used for ordinary fitting, including the built-in functions that are available using the CurveFit operation. If you should write a user-defined fitting function with the same name as a built-in fit function, the user-defined function will be used (this is strongly discouraged).

Every function specification must include an appropriate coefficient wave, pre-loaded with initial guesses.

The comma between each function specification is optional.

The keyword-value pairs are optional, and are used to communicate further options on a function-by-function basis. Available keywords are:

HOLD=*holdstr*
: Indicates that a fit coefficient should be held fixed during fitting. *holdstr* works just like the hold string specified via the /H flag for normal fitting, but applies only to the coefficient wave associated with the fit function it appears with.

  If you include HOLD in a string expression (the {`string=fitSpecStr`} syntax), you must escape the quotation marks around the hold string.

  If you use the command-line syntax {{`func1,coef1,HOLD=`*`holdStr`*}, `...`}, *holdStr* may be a reference to a global variable acquired using SVAR, or it may be a quoted literal string.

  If you use {`string=`*`fitSpecStr`*}, *fitSpecStr* is parsed at run-time outside the context of any running function. Consequently, you cannot use a general string expression. You can use either `HOLD="quotedLiteralString"` or `HOLD=root:globalString`.

CONST={*constants*}
: Sets the values of constants in the fitting function. So far, only two built-in functions take constants: exp_XOffset and dblexp_XOffset. They each take just one constant (the X offset), so you will have a "list" of one number inside the braces.

EPSW=*epsilonWave*
: Specifies a wave holding epsilon values. Use only with a user-defined fitting function to set the differencing interval used to calculate numerical estimates of derivatives of the fitting function.

STRC=*structureInstance*
: Specifies an instance of the structure to FuncFit when using a structure fit function. *structureInstance* is an instance that was initialized by a user-defined function that invokes FuncFit. This keyword (and structure fitting functions) can be used only

when calling FuncFit from within a user-defined function. See **Structure Fit Functions** on page III-226 for more details.

For more details, and for examples of sums of fit functions in use, **Fitting Sums of Fit Functions** on page III-213.

See Also

The **CurveFit** operation for parameter details. See also **FuncFitMD** for user-defined multivariate fits to data in a multidimensional wave.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See **Using the Curve Fitting Dialog** on page III-159, especially the section **Fitting to a User-Defined Function** on page III-171.

For details on the form of a user-defined function, see **User-Defined Fitting Function: Detailed Description** on page III-217.

FuncFitMD

FuncFitMD [***flags***] ***fitFuncName, cwaveName, waveName*** [***flag parameters***]

The FuncFitMD operation performs a curve fit to the specified multivariate user defined *fitFuncSpec*. FuncFitMD handles gridded data sets in multidimensional waves. Most parameters and flags are the same as for the **CurveFit** and **FuncFit** operations; differences are noted below.

cwaveName is a 1D wave containing the fitting coefficients, and *functionName* is the user-defined fitting function, which has 2 to 4 independent variables.

FuncFitMD operation parameters are grouped in the following categories: flags, parameters (*fitFuncName*, *cwaveName*, *waveName*), and flag parameters. The sections below correspond to these categories. Note that flags must precede the *fitFuncName* and flag parameters must follow *waveName*.

Flags

/L=*dimSize* Sets the dimension size of the wave created by the auto-trace feature, that is, /D without destination wave. The wave fit_*waveName* will be a multidimensional wave of the same dimensionality as *waveName* that has *dimSize* elements in each dimension. That is, if you are fitting to a matrix wave, fit_*waveName* will be a square matrix that has dimensions *dimSize* X*dimSize*. **Beware**: *dimSize* =100 requires 100 million points for a 4-dimensional wave!

Parameters

fitFuncName User-defined function to fit to, which must be a function taking 2 to 4 independent variables.

cwaveName 1D wave containing the fitting coefficients.

waveName The wave containing the dependent variable data to be fit to the specified function. For functions of just one independent variable, the dependent variable data is often referred to as "Y data". You can fit to a subrange of the wave by supplying (*startX*,*endX*) or [*startP*,*endP*] for each dimension after the wave name. See **Wave Subrange Details** below for more information on subranges of waves in curve fitting.

Flag Parameters

These flag parameters must follow *waveName*.

/E=*ewaveName* A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave.

/T=*twaveName* Like /X except for the T independent variable. This is a 1D wave having as many elements as *waveName* has chunks.

/X=*xwaveName* The X independent variable values for the data to fit come from *xwaveName* instead of from the X scaling of *waveName*. This is a 1D wave having as many elements as *waveName* has rows.

/Y=*ywaveName* Like /X except for the Y independent variable. This is a 1D wave having as many elements as *waveName* has columns.

/Z=*ywaveName* Like /X except for the Z independent variable. This is a 1D wave having as many elements as *waveName* has layers.

/NWOK Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to FuncFitMD is normally treated as an error. By using /NWOK, you are telling FuncFitMD that a null wave reference is

not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls FuncFitMD with optional waves.

The waves affected are the X wave or waves (/X), the Y spacing wave (/Y), the Z spacking wave (/Z) the T spacing wave (/T), weight wave (/W), epsilon wave (/E) and mask wave (/M). The destination wave (/D=wave) and residual wave (/R=wave) are also affected, but the situation is more complicated because of the dual use of /D and /R to mean "do autodestination" and "do autoresidual". See /AR and /AD.

If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.

Note: To work properly this flag must be the last one in the command.

Details

Auto-residual (/R with no wave specified) and auto-trace (/D with no wave specified) for functions having two independent variables are plotted in a separate graph window if *waveName* is plotted as a contour or image in the top graph. An attempt is made to plot the model values and residuals in the same way as the input data.

By default the auto-trace and auto-residual waves are 50x50 or 25x25x25 or 15x15x15x15. Use /L=*dimSize* for other sizes. Make your own wave and use /D=*waveName* or /R=*waveName* if you want a wave that isn't square. In this case, the wave dimensions must be the same as the dependent data wave.

Confidence bands are not available for multivariate fits.

Wave Subrange Details

Almost any wave you specify to FuncFitMD can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command; see **Subrange Display Syntax** on page II-288 for details. Note that the dependent variable data (*waveName*) must be a multidimensional wave; this requires an extension of the subrange syntax to allow a multidimensional subrange. See **Wave Subrange Details** on page V-194 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for **CurveFit** apply to FuncFitMD as well.

A subrange could be used to pick a plane from a 3D wave for fitting using a fit function taking two independent variables:

```
Make/N=(100,100,3) DepData
FuncFitMD fitfunc2D, myCoefs, DepData[][][0] …
```

See Also

The **CurveFit** operation for parameter details.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See **Using the Curve Fitting Dialog** on page III-159, especially the section **Fitting to a User-Defined Function** on page III-171.

For details on the form of a user-defined function, see **User-Defined Fitting Function: Detailed Description** on page III-217.

FUNCREF

FUNCREF *protoFunc func* [**= *funcSpec***]

Within a user function, FUNCREF is a reference that creates a local reference to a function or a variable containing a function reference.

When passing a function as an input parameter to a user function, the syntax is:

`FUNCREF` *protoFunc func*

In this FUNCREF reference, *protoFunc* is a function that specifies the format of the function that can be passed by the FUNCREF, and *func* is a function reference used as an input parameter.

When you declare a function reference variable within a user function, the syntax is:

`FUNCREF` *protoFunc* `func =` *funcSpec*

Here, the local FUNCREF variable, `func`, is assigned a *funcSpec*, which can be a literal function name, a $ string expression that evaluates at runtime, or another FUNCREF variable.

See Also

Function References on page IV-84 for an example and further usage details.

FuncRefInfo

FuncRefInfo(*funcRef*)

The FuncRefInfo function returns information about a **FUNCREF**.

Parameters

funcRef is a function reference variable declared by a FUNCREF statement in a user-defined function.

Details

FuncRefInfo returns a semicolon-separated keyword/value string containing the following information:

Keyword	Information
NAME	The name of the reference function or "" if the FUNCREF variable has not been assigned to point to a function.
ISPROTO	0 if the FUNCREF variable has been assigned to point to a function.
	1 if it has not been assigned and therefore still points to the prototype function.
ISXFUNC	0 if it points to a user-defined function.
	1 if the FUNCREF points to an external function.

See Also

Function References on page IV-84 and **FUNCREF** on page V-197.

Function

Function [[/C /D /S /DF /WAVE] *functionName*([*parameters*])

The Function keyword introduces a user-defined function in a procedure window.

The optional flags specify the return value type, if any, for the function.

Flags

/C	Returns a complex number.
/D	Returns a double-precision number. Obsolete, accepted for backward compatibility.
/S	Returns a string.
/DF	Returns a data folder reference. See **Data Folder Reference Function Results** on page IV-64.
/WAVE	Returns a wave reference. See **Wave Reference Function Results** on page IV-60.

Details

If you omit all flags, the result is a scalar double-precision number.

The /D flag is not needed because all numeric return values are double-precision.

The /DF and /WAVE flags require Igor Pro 6.1 or later.

See Also

Chapter IV-3, **User-Defined Functions** and **Function Syntax** on page IV-29 for further information.

FunctionInfo

FunctionInfo(*functionNameStr* [, *procedureWinTitleStr*])

The FunctionInfo function returns a keyword-value pair list of information about the user-defined or external function name in *functionNameStr*.

Parameters

functionNameStr a string expression containing the name or multipart name of a user-defined or external function. *functionNameStr* is usually just the name of a function.

To return information about a static function, supply both the module name and the function name in MyModule#MyFunction format (see **Regular Modules** on page IV-212), or specify the function name and *procedureWinTitleStr* (see below).

To return information about a function in a different independent module, supply the independent module name in addition to any module name and function name (a double or triple name):

Name	What It Refers To
MyIndependentModule#MyFunction	Refers to a non-static function in an independent module.
MyIndependentModule#MyModule#MyFunction	Refers to a static function in a procedure file with `#pragma moduleName=MyModule` in an independent module.

(See **Independent Modules** on page IV-214 for details on independent modules.)

The optional *procedureWinTitleStr* can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf") in which to search for the named user-defined function. The information about the named function in the specified procedure window is returned.

The *procedureWinTitleStr* parameter makes it possible to select one of several static functions with identical names among different procedure windows, even if they do not contain a `#pragma moduleName=myModule` statement.

If you execute this command:

```
SetIgorOption IndependentModuleDev=1
```

then *procedureWinTitleStr* can also be a title followed by an independent module name in brackets to return information about the named function in the procedure window of the given title that belongs to named independent module.

procedureWinTitleStr can also be just an independent module name in brackets to return information about the named nonstatic function in any procedure window that belongs to named independent module.

Details

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

User-Defined and External Functions

Keyword	Information Following Keyword
`NAME`	The name of the function. Same as contents of *functionNameStr* in most cases. Just the function name if you use the `module#function` format.
`TYPE`	Value is "UserDefined" or "XFunc".
`RETURNTYPE`	Number giving the return type of the function. See the table **Return Type and Parameter Type Codes** on page V-200.
`N_PARAMS`	Number of parameters for this function.
`PARAM_`*n*`_TYPE`	Number encoding the type of each parameter. There will be N of these keywords, one for each parameter. The part shown as *n* will be a number from 0 to N.

See **Examples** for a method for decoding these keywords.

User-Defined Functions Only

Keyword	Information Following Keyword	
PROCWIN	Title of procedure window containing the function definition.	
MODULE	Module containing function definition (see **Regular Modules** on page IV-212).	
INDEPENDENTMODULE	Independent module containing function definition (see See **Independent Modules** on page IV-214).	
SPECIAL	The value part has one of three values:	
	no:	Not a "special" function.
	static:	Is a static function. Use the module#function format to get info about static functions.

User-Defined Functions Only

Keyword	Information Following Keyword
	override: Function is an override function. See **Function Overrides** on page IV-84.
SUBTYPE	The function subtype, for instance **FitFunc**. See **Procedure Subtypes** on page V-12 for others.
PROCLINE	Line number within the procedure window of the function definition.
VISIBLE	Either "Yes" or "No". Set to No in the unlikely event that the function is defined in an invisible file.
N_OPT_PARAMS	Number of optional parameters. Usually zero.

External Functions Only

Keyword	Information Following Keyword
XOP	Name of the XOP module containing the function.

Return Type and Parameter Type Codes

Type	Code	Code in Hex
Complex	1	0x1
Variable	4	0x4
Single Precision	2	0x2
Double Precision	4	0x4
Byte	8	0x8
16-bit Integer	16	0x10
32-bit Integer	32	0x20
Unsigned	64	0x40
Data folder reference	256	0x100
Structure	512	0x200
Function reference	1024	0x400
Pass by reference parameter	4096	0x1000
String	8192	0x2000
Wave	16384	0x4000

Functions can return either a numeric value or a string. A numeric value is always double precision and my be complex. Thus, the return type will always be one of the values 4 (numeric), 5 (4+1 for complex numeric) or 8192 (string).

These codes may be combined to indicate combinations of attributes. For instance, the code for a variable is 4 and the code for complex is 1. Consequently, the code for a complex variable is 5. The code for a complex variable passed by reference is (4+1+4096) = 4101.

Variables are always double-precision, hence the code of 4.

Waves may have a variety of codes. Numeric waves will combine with one of the number type codes such as 2 or 16. This does not reflect the numeric type of any actual wave, but rather any flag you may have used in the Wave reference. Thus, if the beginning of your function looks like

```
Function myFunc(w)
    Wave w
```

the code for the parameter w will be 16386 (16384 + 2) indicating a single-precision wave. You can use a numeric type flag with the Wave reference:

```
Function myFunc(w)
    Wave/I w
```

In this case, the code will be 16416 (16384 + 32).

Such codes are not very useful, as it is very rare to use a numeric type flag because the numeric type will be resolved correctly at runtime regardless of the flag.

A text wave has no numeric type, so its code is exactly 16384. Thus, the numeric type part of the code for a numeric wave serves to distinguish a numeric wave from a text wave.

Examples

This function formats function information nicely and prints it in the history window in an organized fashion. You can copy it into the Procedure window to try it out. It uses the function `interpretParamType()` below to print a human-readable version of the parameter and return types. To try `PrintFuncInfo()`, you will need to copy the code for `interpretParamType()` as well.

```
Function PrintFuncInfo(FunctionName)
    String FunctionName

    String infostr = FunctionInfo(FunctionName)
    if (strlen(infostr) == 0)
        print "The function "+FunctionName+" does not exist."
        return -1
    endif

    print "Name: ", StringByKey("NAME", infostr)

    String typeStr = StringByKey("TYPE", infostr)
    print "Function type: ", typeStr
    Variable IsUserDefined = CmpStr(typeStr, "UserDefined")==0

    // It's not really necessary to use an IF statement here;
    // it simply prevents lines with blank information being printed for an XFUNC.

    if (IsUserDefined)
        print "Module: ", StringByKey("MODULE", infostr)
        print "Procedure window: ", StringByKey("PROCWIN", infostr)
        print "Subtype: ", StringByKey("SUBTYPE", infostr)
        print "Special? ", StringByKey("SPECIAL", infostr)

        // Note use of NumberByKey to get a numeric key value
        print "Line number: ", NumberByKey("PROCLINE", infostr)
    endif

    // See function interpretParamType() below for example of
    // interpreting type information

    Variable dummy = NumberByKey("RETURNTYPE", infostr)
    String dummyStr = interpretParamType(dummy)
    print "Return type: ", dummy, dummyStr

    Variable nparams = NumberByKey("N_PARAMS", infostr)
    print "Number of Parameters: ", nparams

    Variable nOptParams = 0
    if (IsUserDefined)
        nOptParams = NumberByKey("N_OPT_PARAMS", infostr)
        print "Optional Parameters: ", nOptParams
    endif

    Variable i
    for (i = 0; i < nparams; i += 1)

        // Note how the PARAM_n_TYPE keyword string is constructed here
        String paramKeyStr = "PARAM_"+num2istr(i)+"_TYPE"
        Variable ptype = NumberByKey(paramKeyStr, infostr)

        String output = "Parameter "+num2istr(i)+"; "
        output += "type as number: "+num2istr(ptype)+"; "
        output += "type as string: "+interpretParamType(ptype)
        print output
    endfor
End
```

Function that creates a human-readable string with information about parameter and return types. Note that various attributes of the type info is tested using the bitwise AND operator (&) to test for individual bits. The

constants are expressed as hexadecimal values (prefixed with "0x") to make them more readable (at least to a programmer). Otherwise, 0x4000 would be 16384; at least, 0x4000 is clearly a single-bit constant.

```
Function/S interpretParamType(ptype)
    Variable ptype

    String typeStr = ""

    // flag to tell whether to print out "complex" and "real"
    // We don't want that information on strings and text waves

    Variable wantRC = 1

    if (ptype & 0x4000)              // test for WAVE bit set
        typeStr += "Wave "

        // If *only* wave bit set, its a text wave. A numeric
        // wave has some other information causing the value
        // to be different from 0x4000

        if (ptype == 0x4000)
            typeStr += "text "
            // don't want to print "real" and "complex" for text waves
            wantRC = 0
        endif

    elseif (ptype & 0x2000)          // test for STRING bit set
        typeStr += "String "
        // don't want to print "real" and "complex" for strings
        wantRC = 0
    elseif (ptype & 4)               // test for VARIABLE bit
        typeStr += "Variable "
    elseif (ptype & 0x200)           // test for STRUCTURE bit
        typeStr += "Struct "
        wantRC = 0
    elseif (ptype & 0x400)           // test for FUNCREF bit
        typeStr += "FuncRef "
        wantRC = 0
    endif

    // print "real" and "complex" for numeric objects only
    if (wantRC)
        if (ptype & 1)               // test for COMPLEX bit
            typeStr += "cmplx "
        else
            typeStr += "real "
        endif
    endif

    if (ptype & 0x1000)              // test for PASS BY REFERENCE bit
        typeStr += "reference "
    endif

    return typeStr
End
```

See Also

The **StringByKey** and **NumberByKey** functions.

StringByKey, **NumberByKey**, and **FunctionList** functions.

Regular Modules on page IV-212 and **Independent Modules** on page IV-214.

FunctionList

FunctionList(*matchStr*, *separatorStr*, *optionsStr*)

The FunctionList function returns a string containing a list of built-in or user-defined function names satisfying certain criteria. This is useful for making a string to list functions in a pop-up menu control. Note that if the procedures need to be compiled, then FunctionList will not list user-defined functions.

Parameters

Only functions having names that match *matchStr* string are listed. Use `"*"` to match all names. See **WaveList** for examples.

The first character of *separatorStr* is appended to each function name as the output string is generated. *separatorStr* is usually `";"` for list processing (See **Processing Lists of Waves** on page IV-174 for details on list processing).

Use *optionsStr* to further qualify the list of functions. *optionsStr* is a string containing keyword-value pairs separated by commas. Available options are:

KIND:*nk*

nk=1: List built-in functions.

nk=2: List normal and override user-defined functions.

nk=4: List external functions (defined by an XOP).

nk=8: List only curve fitting functions; must be summed with 1, 2, 4, or 16. For example, use 10 to list user-defined fitting functions.

nk=16: Include static user-defined functions (requires WIN: option).

SUBTYPE:*typeName*

Lists functions that have the type *typeName*. That is, you could use ButtonControl as *typeName* to list only functions that are action procedures for buttons.

VALTYPE:*nv*

Restricts list to functions whose return type is a certain kind.

nv=1: Real-valued functions.

nv=2: Complex-valued functions.

nv=4: String functions.

nv=8: WAVE functions

nv=16: DFREF functions

Use a sum of these values to include more than one type. The return type is not restricted if this option is omitted.

NPARAMS:*np*

Restricts the list to functions having exactly *np* parameters. Omitting this option lists functions having any number of parameters.

NINDVARS:*ni*

Restricts the list to fitting functions for exactly *ni* independent variables. NINDVARS is ignored if you have not elected to list curve fitting functions using the KIND option. Functions for any number of independent variables are listed if the NINDVARS option is omitted.

WIN:*windowTitle*

Lists functions that are defined in the procedure window with the given title. "Procedure" is the title of the built-in procedure window.

Note: Because the *optionsStr* keyword-value pairs are comma separated and procedure window names can have commas in them, the WIN:keyword must be the last one specified.

WIN:windowTitle [*independentModuleName*]

Lists functions that are defined in the named procedure window that belongs to the independent module *independentModuleName*. See **Independent Modules** on page IV-214 for details. Requires `SetIgorOption IndependentModuleDev=1`, otherwise no functions are listed.

Requires *independentModuleName*=ProcGlobal or SetIgorOption independentModuleDev=1, otherwise no functions are listed.

Note: The syntax is literal and strict: the window title must be followed by one space and a left bracket, followed directly by the independent module name and a closing right bracket.

WIN:[*independentModuleName*]

Lists functions that are defined in any procedure file that belongs to the named independent module.

Requires *independentModuleName*=ProcGlobal or SetIgorOption independentModuleDev=1, otherwise no functions are listed.

Note: The syntax is literal and strict: 'WIN:' must be followed by a left bracket, followed directly by the independent module name and a closing right bracket, like this:

```
FunctionList(...,"WIN:[myIndependentModuleName]")
```

Examples

To list user-defined fitting functions for two independent variables:

```
Print FunctionList("*",";","KIND:10,NINDVARS:2")
```

To list button-control functions that start with the letter *b* (note that button-control functions are user-defined):

```
Print FunctionList("b*",";","KIND:2,SUBTYPE:ButtonControl")
```

See Also

Independent Modules on page IV-214.

For details on procedure subtypes, see **Procedure Subtypes** on page IV-179, as well as **Button**, **CheckBox**, **SetVariable**, and **PopupMenu**.

The **DisplayProcedure** operation and the **MacroList**, **OperationList**, **StringFromList**, and **WinList** functions.

FunctionPath

FunctionPath(*functionNameStr*)

The FunctionPath function returns a path to the file containing the named function. This is useful in certain specialized cases, such as if a function needs access to a lookup table of a large number of values.

The most likely use for this is to find the path to the file containing the currently running function. This is done by passing `""` for *functionNameStr*, as illustrated in the example below.

The returned path uses Macintosh syntax regardless of the current platform. See **Path Separators** on page III-398 for details.

If the procedure file is a normal standalone procedure file, the returned path will be a full path to the file such as `"hd:Igor Pro Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf"`.

If the function resides in the built-in procedure window the returned path will be `":Procedure"`. If the function resides in a packed procedure file, the returned path will be `":<packed procedure window title>"`.

If FunctionPath is called when procedures are in an uncompiled state, it returns ":".

Parameters

If *functionNameStr* is `""`, FunctionPath returns the path to the currently executing function or `""` if no function is executing.

Otherwise FunctionPath returns the path to the named function or `""` if no function by that name exists.

Examples

This example loads a lookup table into memory. The lookup table is stored as a wave in an Igor binary file.

```
Function LoadMyLookupTable()
   String path

   path = FunctionPath("")    // Path to file containing this function.
   if (CmpStr(path[0],":") == 0)
      // This is the built-in procedure window or a packed procedure
      // file, not a standalone file. Or procedures are not compiled.
      return -1
   endif

   // Create path to the lookup table file.
   path = ParseFilePath(1, path, ":", 0, 0) + "MyTable.ibw"

   String dfSave = GetDataFolder(1)

   // A previously-created place to store my private data.
   SetDataFolder root:Packages:MyData

   // Load the lookup table.
   LoadWave/O path

   SetDataFolder dfSave

   return 0
End
```

See Also

The **FunctionList** function.

GalleryGlobal

GalleryGlobal#*pictureName*

The GalleryGlobal keyword is used in an independent module to reference a picture in the global picture gallery which you can view by choosing Misc→Pictures.

See Also

See **Independent Modules and Pictures** on page IV-220.

gamma

gamma(*num*)

The gamma function returns the value of the gamma function of *num*. If *num* is complex, it returns a complex result. Note that the return value for *num* close to negative integers is NaN, not ±Inf.

See Also

The **gammln** function.

gammaInc

gammaInc(*a*, *x* [, *upperTail*])

The gammaInc function returns the value of the incomplete gamma function, defined by the integral

$$\Gamma(a,x) = \int_x^\infty e^{-t}t^{e-1}dt$$

If *upperTail* is zero, the limits of integration are 0 to x. If *upperTail* is absent, it defaults to 1, and the limits of integration are x to infinity, as shown. Note that `gammaInc(a, x) = gamma(a) - gammaInc(a, x, 0)`.

Defined for x > 0, a ≥ 0 (*upperTail* = zero or absent) or a > 0 (*upperTail* = 0).

See Also

The **gamma**, **gammp**, and **gammq** functions.

gammaNoise

gammaNoise(*a* [, *b*])

The gammaNoise function returns a pseudo-random value from the gamma distribution

$$f(x) = \frac{x^{a-1}\exp\left(-\frac{x}{b}\right)}{b^a\Gamma(a)}, \qquad x>0, a>0, b>0$$

whose mean is *ab* and variance is ab^2. For backward compatibility you can omit the parameter *b* in which case its value is set to 1. When $a \rightarrow 1$ gammaNoise reduces to **expnoise**.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

References

Marsaglia, G., and W. W. Tsang, *ACM*, 26, 363-372, 2000.

See Also

The **SetRandomSeed** operation.

Noise Functions on page III-332.

Chapter III-12, **Statistics** for a function and operation overview.

gammln

gammln(*num* [, *accuracy*])

The gammln function returns the natural log of the gamma function of *num*, where *num* > 0. If *num* is complex, it returns a complex result. Optionally, *accuracy* can be used to specify the desired fractional accuracy. If *num* is complex, it returns a complex result. In this case, *accuracy* is ignored.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7}, that means that you wish that the absolute value of $(f_{actual} - f_{returned})/f_{actual}$ be less than 10^{-7}.

For backward compatibility, if you don't include *accuracy*, gammln uses older code that achieves an accuracy of about $2x10^{-10}$.

With *accuracy*, newer code is used that is both faster and more accurate. The output has fractional accuracy better than $1x10^{-15}$ except for values near zero, where the absolute accuracy ($f_{actual} - f_{returned}$) is better than $2x10^{-16}$.

The speed of calculation depends only weakly on accuracy. Higher accuracy is significantly slower than lower accuracy only for *num* between 6 and about 10.

See Also

The **gamma** function.

gammp

gammp(*a, x* [, *accuracy*])

The gammp function returns the regularized incomplete gamma function P(*a,x*), where $a > 0$, $x \geq 0$. Optionally, *accuracy* can be used to specify the desired fractional accuracy. Same as `gammaInc(a, x, 0)/gamma(a)`.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7}, that means that you wish that the absolute value of $(f_{actual} - f_{returned})/f_{actual}$ be less than 10^{-7}.

For backward compatibility, if you don't include *accuracy*, gammp uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

The ability of gammp to return a value having full fractional accuracy is limited by double-precision calculations. This means that it will mostly have fractional accuracy better than about 10^{-15}, but this is not guaranteed, especially for extreme values of *a* and *x*.

See Also

The **gammaInc** and **gammq** functions.

gammq

gammq(*a, x* [, *accuracy*])

The gammq function returns the regularized incomplete gamma function 1-P(*a,x*), where $a > 0$, $x \geq 0$. Optionally, *accuracy* can be used to specify the desired fractional accuracy. Same as `gammaInc(a, x)/gamma(a)`.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7}, that means that you wish that the absolute value of $(f_{actual} - f_{returned})/f_{actual}$ be less than 10^{-7}.

For backward compatibility, if you don't include *accuracy*, gammq uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

The ability of gammq to return a value having full fractional accuracy is limited by double-precision calculations. This means that it will mostly have fractional accuracy better than about 10^{-15}, but this is not guaranteed, especially for extreme values of *a* and *x*.

See Also

The **gammaInc** and **gammp** functions.

Gauss

Gauss(x,*xc*,*wx* [,y,*yc*,*wy* [,z,*zc*,*wz* [,t,*tc*,*wt*]]])

The Gauss function returns a normalized Gaussian for the specified dimension.

$$\text{Gauss}(\underline{r}, \underline{c}, \underline{w}) = \prod_{i=1}^{n} \frac{1}{w_i \cdot \sqrt{2\pi}} \exp\left\{-\frac{1}{2}\left(\frac{r_i - c_i}{w_i}\right)^2\right\}$$, where n is the number of dimensions.

Parameters

xc, *yc*, *zc*, and *tc* are the centers of the Gaussian in the X, Y, Z, and T directions, respectively.

wx, *wy*, *wz*, and *wt* are the widths of the Gaussian in the X, Y, Z, and T directions, respectively.

Note that w_i here is the standard deviation of the Gaussian. This is different from the width parameter in the gauss curve fitting function, which is sqrt(2) times the standard deviation.

Note also that the Gauss function lacks the cross-correlation parameter that is included in the Gauss2D curve fitting function.

Examples

```
Make/n=100 eee=gauss(x,50,10)
Print area(eee,-inf,inf)
  0.999999
Make/n=(100,100) ddd=gauss(x,50,10,y,50,15)
Print area(ddd,-inf,inf)
  0.999137
```

Gauss1D

Gauss1D(*w, x*)

The Gauss1D function returns the value of a Gaussian peak defined by the coefficients in the wave *w*. The equation is the same as the Gauss curve fit:

$$w[0] = w[0] + w[1]\exp\left[-\left(\frac{x - w[2]}{w[3]}\right)^2\right].$$

Examples

Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range:

```
Make/O/N=100 junkg                        // fake data wave
Setscale/I x -1,1,junkg
Display junkg
junkg = 1+2.5*exp(-((x-.5)/.3)^2)+gnoise(.1)
Duplicate/O junkg, junkgfit
junkgfit = NaN
AppendToGraph junkgfit
CurveFit gauss junkg[50,99] /D=junkgfit
// now extend the model trace
junkgfit = Gauss1D(w_coef, x)
```

See Also

The **CurveFit** operation.

Gauss2D

Gauss2D(*w, x, y*)

The Gauss2D function returns the value of a two-dimensional Gaussian peak defined by the coefficients in the wave *w*. The equation is the same as the Gauss2D curve fit:

$$w[0] + w[1]\exp\left[\frac{-1}{2(1 - w[6]^2)}\left(\left(\frac{x - w[2]}{w[3]}\right)^2 + \left(\frac{y - w[4]}{w[5]}\right)^2 - \frac{2w[6](x - w[2])(y - w[4])}{w[3]w[5]}\right)\right].$$

Examples

Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range (watch out for the very long wave assignment to junkg2D):

```
Make/O/N=(100,100) junkg2D                        // fake data wave
Setscale/I x -1,1,junkg2D
Setscale/I y -1,1,junkg2D
Display; AppendImage junkg2D
//Caution! Next command wrapped to fit page:
junkg2D = -1 + 2.5*exp((-1/(2*(1-.4^2)))*(((x-.1)/.2)^2+((y+.2)/.35)^2+2*.4*
          ((x-.1)/.2)*((y+.2)/.35)))
junkg2D += gnoise(.01)
Duplicate/O junkg2D, junkg2Dfit
junkg2Dfit = NaN
AppendMatrixContour junkg2Dfit
CurveFit gauss2D junkg2D[20,80][10,70] /D=junkg2Dfit[20,80][10,70]
// now extend the model trace
junkg2Dfit = Gauss2D(w_coef, x, y)
```

See Also

The **CurveFit** operation.

gcd

gcd(*A, B*)

The gcd function calculates the greatest common divisor of *A* and *B*, which are both assumed to be integers.

Examples

Compute least common multiple (LCM) of two integers:

```
Function LCM(a,b)
   Variable a, b
   return((a*b)/gcd(a,b))
End
```

GetAxis

GetAxis [**/W=*winName* /Q**] ***axisName***

The GetAxis operation determines the axis range and sets the variables V_min and V_max to the minimum and maximum values of the named axis.

Parameters

axisName is usually `"left"`, `"right"`, `"top"` or `"bottom"`, though it may also be the name of a free axis such as `"VertCrossing"`.

Flags

/Q	Prevents values of V_flag, V_min, and V_max from being printed in the history area. The results are still stored in the variables.
/W=*winName*	Retrieves axis info from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

GetAxis sets V_min according to the bottom of vertical axes or left of horizontal axes and V_max according to the top of vertical axes or right of horizontal axes. It also sets the variable V_flag to 0 if the specified axis is actually used in the graph, or to 1 if it is not.

See Also

The **AxisInfo** function.

GetDataFolder

GetDataFolder(*mode* [, *dfr*])

The GetDataFolder function returns a string containing the name of or full path to the current data folder or, if *dfr* is present, the specified data folder.

For Igor Pro 6.1 or later, **GetDataFolderDFR** is preferred.

Parameters

If *mode*=0, it returns just the name of the data folder.

If *mode*=1, GetDataFolder returns a string containing the full path to the data folder.

dfr, if present, specifies the data folder of interest. This parameter was added in Igor Pro 6.1.

Details

GetDataFolder can be used to save and restore the current data folder in a procedure. However, as of Igor Pro 6.1, GetDataFolderDFR is preferred for that purpose.

Examples

```
String savedDataFolder = GetDataFolder(1)          // Save
SetDataFolder root:
Variable/G gGlobalRootVar
SetDataFolder savedDataFolder                      // and restore
```

See Also

Chapter II-8, **Data Folders**.

The **SetDataFolder** operation and **GetDataFolderDFR** function.

GetDataFolderDFR

GetDataFolderDFR()

The GetDataFolderDFR function returns the data folder reference for the current data folder.

Requires Igor Pro 6.1 or later.

Details

GetDataFolderDFR can be used to save and restore the current data folder in a procedure. It is like GetDataFolder but returns a data folder reference rather than a string.

Example

```
DFREF saveDFR = GetDataFolderDFR()                // Save
SetDataFolder root:
Variable/G gGlobalRootVar
SetDataFolder saveDFR                             // and restore
```

See Also

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-61.

The **SetDataFolder** operation.

GetDefaultFont

GetDefaultFont(*winName*)

The GetDefaultFont function returns a string containing the name of the default font for the named window or subwindow.

Parameters

If *winName* is null (that is, `""`) returns the default font for the experiment.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

Only graph windows and the experiment as a whole have default fonts. If *winName* is the name of a window other than a graph (e.g., a layout), or if *winName* is not the name of any window, GetDefaultFont returns the experiment default font.

In user-defined functions, font names are usually evaluated at compile time. To use the output of GetDefaultFont in a user-defined function, you will usually need to build a command as a string expression and execute it with the **Execute** operation.

Examples

```
String fontName = GetDefaultFont("Graph0")
String command= "SetDrawEnv fname=\"" + fontName + "\", save"
Execute command
```

See Also

The **GetDefaultFontSize**, **GetDefaultFontStyle**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

GetDefaultFontSize

GetDefaultFontSize(*graphNameStr, axisNameStr*)

The GetDefaultFontSize function returns the default font size of the graph or of the graph's axis (in points) in the specified window or subwindow.

Details

If *graphNameStr* is `""` the top graph is examined.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

If *axisNameStr* is `""`, the font size of the default font for the graph is returned.

If named axis exists, the default font size for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

See Also
The **GetDefaultFont**, **GetDefaultFontStyle**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

GetDefaultFontStyle

GetDefaultFontStyle(*graphNameStr, axisNameStr*)
The GetDefaultFontStyle function returns the default font style of the graph or of the graph's axis in the specified window or subwindow.

Details
If *graphNameStr* is `""` the top graph is examined.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

If *axisNameStr* is `""`, the font style of the default font for the graph is returned.

If named axis exists, the default font style for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

The returned value is a binary coded number with each bit identifying one aspect of the font style as follows:

bit 0:	Bold.
bit 1:	Italic.
bit 2:	Underline.
bit 3:	Outline (*Macintosh only*).
bit 4:	Shadow (*Macintosh only*).
bit 5:	Condensed (*Macintosh only*).
bit 6:	Extended (*Macintosh only*).

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

See Also
The **GetDefaultFont**, **GetDefaultFontSize**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

GetDimLabel

GetDimLabel(*waveName, dimNumber, dimIndex*)
The GetDimLabel function returns a string containing the label for the given dimension or dimension element.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks.

If *dimIndex* is -1, it returns the label for the entire dimension. If *dimIndex* is ≥ 0, it returns the dimension label for that element of the dimension.

See Also
The **SetDimLabel** function. **Dimension Labels** on page II-109 for further usage details and examples.

GetFileFolderInfo

GetFileFolderInfo [***flags***] [***fileOrFolderNameStr***]
The GetFileFolderInfo operation returns information about a file or folder.

Parameters
fileOrFolderNameStr specifies the file (or folder) for which information is returned. It is optional if /P=*pathName* and /D are specified, in which case information about the directory associated with *pathName* is returned.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-398 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

If Igor can not determine the location of the file from *fileOrFolderNameStr* and *pathName*, it displays a dialog allowing you to specify the file to be examined. Use /D to select a folder.

Flags

/D — Uses the Select Folder dialog rather than Open File dialog when *pathName* and *fileOrFolderNameStr* do not specify an existing file or folder.

/P=*pathName* — Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.

/Q — No information printed to the history window.

/Z[=*z*] — Prevents procedure execution from aborting if GetFileFolderInfo tries to get information about a file or folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

- /Z=0: Same as no /Z at all.
- /Z=1: Used for getting information for a file or folder only if it exists. /Z alone has the same effect as /Z=1.
- /Z=2: Used for getting information for a file or folder if it exists and displaying a dialog if it does not exist.

Variables

GetFileFolderInfo returns information in the following variables:

`V_flag`
- 0: File or folder was found.
- -1: User cancelled the Open File dialog.
- Other: An error occurred, such as the specified file or folder does not exist.

`S_path` — File system path of the selected file.

`V_isFile` — 1: *fileOrFolderNameStr* is a file.

`V_isFolder` — 1: *fileOrFolderNameStr* is a folder.

`V_isInvisible` — 1: File is invisible (*Macintosh*) or Hidden (*Windows*).

`V_isReadOnly` — Set if the file is locked (*Macintosh*) or is read-only (*Windows*).

On Windows, V_isReadonly is either 0 (unlocked) or 1 (locked). To set this manually, right-click the file and choose "Properties", then select or deselect the "read-only" checkbox.

On Macintosh, V_isReadonly is a bitmap of two settings:

- 0: Unlocked.
- 1: "Locked" with the Finder. Only files can be locked this way.

  You set this kind of locking with the Finder's Get Info window by selecting the "Locked" checkbox.
- 2: "File Locked" as with ResEdit. You can't set this kind of locking with the Finder, but applications can. See **SetFileFolderInfo**.
- 3: Both kinds of locking are set.

`V_creationDate` — Number of seconds since midnight on January 1, 1904 when the file or folder was first created. Use **Secs2Date** to get a text format date.

`V_modificationDate` — Number of seconds since midnight on January 1, 1904 when the file or folder was last modified. Use **Secs2Date** to get a text format date.

`V_isAliasShortcut` — 1: File is an alias (*Macintosh*) or a shortcut (*Windows*) and S_aliasPath is also set.

If *fileOrFolderNameStr* refers to a file (not a folder), GetFileFolderInfo returns additional information in the following variables:

`S_aliasPath` — Full path to the file or folder that is the source for an alias (*Macintosh*) or a shortcut (*Windows*).

When the source is a folder, S_aliasPath ends with a ":" character.

`V_isStationery` — 1: The stationery bit is set (*Macintosh*) or (*Windows*) the file type is one of the stationery file types (.pxt, .uxt, .ift).

S_fileType	Four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment). On Windows, these codes are fabricated by translating from the equivalent file name extensions, such as .txt and .pxp.
S_creator	Four-character creator code, such as 'IGR0' (Igor Pro creator code). On Windows, S_creator is set to 'IGR0' if the file name extensions is one of those registered to Igor Pro, such as .pxp or .bwav (but not .txt). For other registered extensions, S_creator is set to the full file path of the registered application. Otherwise it is set to "".
V_logEOF	Number of bytes in the file data fork. For other forks, use **Open**/F and **FStatus**.
V_version	Version number of the file. On Macintosh, this is the value in the vers(1) resource. On Windows, a file version such as 3.10.2.1 is returned as 4.021: use S_fileVersion to avoid the problem of the second digit overflowing into the first digit. "0": File version can't be determined, or the file can't be examined because it is already open.
S_fileVersion	The file version as a string, added in Igor 5.02. On Macintosh, this is just a string representation of V_Version. On Windows, a file version such as 3.10.2.1 is returned as "3.10.2.1". "0": (*Macintosh*) file version can't be determined. "0.0.0.0": (*Windows*) file version can't be determined.

Details

You can change some of the file information by using **SetFileFolderInfo**.

Examples

Print the modification date of a file:

```
GetFileFolderInfo/Z "Macintosh HD:folder:afile.txt"
if( V_Flag == 0 && V_isFile )                    // file exists
   Print Secs2Date(V_modificationDate,0), Secs2Time(V_modificationDate,0)
endif
```

Determine if a folder exists (easier than creating a path with NewPath and then using PathInfo):

```
GetFileFolderInfo/Z "Macintosh HD:folder:subfolder"
if( V_Flag && V_isFolder )
   Print "Folder Exists!"
endif
```

Find the source for a shortcut or alias:

```
GetFileFolderInfo/Z "Macintosh HD:fileThatIsAlias"
if( V_Flag && V_isAliasShortcut )
   Print S_aliasPath
endif
```

See Also

The **SetFileFolderInfo**, **PathInfo**, **ImageFileInfo**, and **FStatus** operations. The **IndexedFile**, **Secs2Date**, and **ParseFilePath** functions.

GetErrMessage

GetErrMessage(*errorCode* [, *substitutionOption*])

GetErrMessage returns a string containing an explanation of the error associated with *errorCode*.

Details

errorCode is a value sometimes returned in V_Flag, as per the documentation of the an Igor function or operation; the **Execute** operation is an example.

For a few error codes, the corresponding error message is designed to be combined with "substituted" information available only immediately after the error occurs. An example is the "parameter out of range" error which produces an error message such as "expected number between *x* and *y*". To get the correct error message, you must call GetErrMessage immediately after calling the function or operation that generated the error and you must pass the appropriate value for *substitutionOption* as explained below.

Substitution

Igor maintains two environments which store the substitution information: one for macros created using the Macro, Proc and Window keywords and another for user-defined functions created with the Function keyword. The optional *substitutionOption* parameter gives you the ability to choose between those environments or to not substitute at all. Set *substitutionOption* to one of:

substitutionOption	GetErrMessage Action
0	Substitution values are filled in with "(not avail)". This is the default when *substitutionOption* is not specified.
1	Substitution values are blank.
2	Substitution is performed based on the presumption that the error was received while executing a macro or a command using Igor's command line. This includes a command executed via the Execute operation even from a user-defined function because such commands are executed as if entered in the command line.
3	Substitution is performed based on the presumption that the error was received while executing a user-defined function.

For most purposes you should pass 3 for *substitutionOption* when the error was generated in a user-defined function other than through the Execute operation and pass 2 otherwise.

Examples

```
// Macro, Execute or command line
Execute/Q/Z "Duplicate/O nonexistentWave, dup"
Print GetErrMessage(V_Flag,2)
```

Prints:

```
    expected wave name
```

```
// Function example
Function Test()
    Make/O/N=(2,2) data= 0
    FilterIIR/COEF=data/LO=999/Z data    // purposely wrong /LO value
    Print GetErrMessage(V_Flag)
    Print GetErrMessage(V_Flag,1)
    Print GetErrMessage(V_Flag,2)
    Print GetErrMessage(V_Flag,3)
End

Test()
```

Prints:

```
  expected (not avail) between (not avail) and (not avail)
  expected  between  and
  expected  between  and
  expected /LO frequency between 0 and 0.5
```

See Also

The **GetRTErrMessage** and **GetRTError** functions.

GetFormula

GetFormula(*objName*)

The GetFormula function returns a string containing the named object's dependency formula. The named object must be a wave, numeric variable or string variable.

Details

Normally an object will have an empty dependency formula and GetFormula will return an empty string (""). If you assign a expression to an object using the := operator or the SetFormula operation, the text on the right side of the := or the parameter to SetFormula is the object's dependency formula and this is what GetFormula will return.

Examples

```
Variable/G dependsOnIt
Make/O wave0 := dependsOnIt*2     //wave0 changes when dependsOnItdoes
Print GetFormula(wave0)
```

Prints the following in the history area:

```
  dependsOnIt*2
```

See Also

See **Dependency Formulas** on page IV-200, and the **SetFormula** operation.

GetIndependentModuleName

GetIndependentModuleName()

The GetIndependentModuleName function returns the name of the currently running Independent Module. If no independent module is running, it returns "ProcGlobal".

See Also

Independent Modules on page IV-214.

IndependentModuleList.

GetIndexedObjName

GetIndexedObjName(*sourceFolderStr, objectType, index*)

The GetIndexedObjName function returns a string containing the name of the indexth object of the specified type in the data folder specified by the string expression.

For Igor Pro 6.1 or later, **GetIndexedObjNameDFR** is preferred.

Parameters

sourceFolderStr can be either ":" or "" to specify the current data folder. You can also use a full or partial data folder path. *index* starts from zero. If no such object exists a zero length string ("") is returned. *objectType* is one of the following values:

objectType	What You Get
1	Waves
2	Numeric variables
3	String variables
4	Data folders

Examples

```
Function PrintAllWaveNames()
    String objName
    Variable index = 0
    do
        objName = GetIndexedObjName(":", 1, index)
        if (strlen(objName) == 0)
            break
        endif
        Print objName
        index += 1
    while(1)
End
```

See Also

The **CountObjects** function, and Chapter II-8, **Data Folders**.

GetIndexedObjNameDFR

GetIndexedObjNameDFR(*dfr, objectType, index*)

The GetIndexedObjNameDFR function returns a string containing the name of the indexth object of the specified type in the data folder referenced by *dfr*.

Requires Igor Pro 6.1 or later.

GetIndexedObjNameDFR is the same as GetIndexedObjName except the first parameter, *dfr*, is a data folder reference instead of a string containing a path.

Parameters

index starts from zero. If no such object exists a zero length string ("") is returned.

objectType is one of the following values:

objectType	What You Get
1	Waves
2	Numeric variables
3	String variables
4	Data folders

Examples

```
Function PrintAllWaveNames()
    String objName
    Variable index = 0
    DFREF dfr = GetDataFolderDFR()    // Reference to current data folder
    do
        objName = GetIndexedObjNameDFR(dfr, 1, index)
        if (strlen(objName) == 0)
            break
        endif
        Print objName
        index += 1
    while(1)
End
```

See Also

Chapter II-8, **Data Folders** and **Data Folder References** on page IV-61.

The **CountObjectsDFR** function.

GetKeyState

GetKeyState(*flags*)

The GetKeyState function returns a bitwise numeric value that indicates the state of certain keyboard keys.

GetKeyState is normally called from a procedure that is invoked directly through a user-defined button or user-defined menu item. The procedure tests the state of one or more modifier keys and adjusts its behavior accordingly.

Another use for GetKeyState is to determine if Escape is pressed. This can be used to detect that the user wants to stop a procedure.

GetKeyState tests the keyboard at the time it is called. It does not tell you if keys were pressed between calls to the function. Consequently, when a procedure uses the escape key to break a loop, the user must press Escape until the running procedure gets around to calling the function.

Parameters

flags is reserved for future use and currently must be zero.

Details

When set, the return value is interpreted bitwise as follows:

Bit 0:	Command (*Macintosh*) or Ctrl (*Windows*) pressed.
Bit 1:	Option (*Macintosh*) or Alt (*Windows*) pressed.
Bit 2:	Shift pressed.
Bit 3:	Caps Lock pressed.
Bit 4:	Control pressed (*Macintosh only*).
Bit 5:	Escape pressed.

To test if a particular key is pressed, do a bitwise AND of the return value with the mask value 1, 2, 4, 8, 16, and 32 for bits 0 through 5 respectively. To test if a particular key and only that key is pressed compare the return value with the mask value.

On Macintosh, it is currently possible to define a keyboard shortcut for a user-defined menu item and then, in the procedure invoked by the keyboard shortcut, to use GetKeyState to test for modifier keys. This is not possible on Windows because the keyboard shortcut will not be activated if a modifier key not specified in the keyboard shortcut is pressed. It is also possible that this ability on Macintosh will be compromised by future operating system changes. On both operating systems, however, you can test for a modifier key when the user chooses a user-defined menu item or clicks a user-defined button using the mouse.

Examples

```
Function ShiftKeyExample()
    Variable keys = GetKeyState(0)

    if (keys == 0)
        Print "No modifier keys are pressed."
    endif

    if (keys & 4)
        if (keys == 4)
            Print "The Shift key and only the Shift key is pressed."
        else
            Print "The Shift key is pressed."
        endif
    endif
End

Function EscapeKeyExample()
    Variable keys

    do
        keys = GetKeyState(0)
        if ((keys & 32) != 0)          // User is pressing escape?
            break
        endif
    while(1)
End
```

See Also

Keyboard Shortcuts on page IV-118. **Setting Bit Parameters** on page IV-12 for details about bit settings.

GetLastUserMenuInfo

GetLastUserMenuInfo

The GetLastUserMenuInfo operation sets variables in the local scope to indicate the value of the last selected user-defined menu item.

Details

GetLastUserMenuInfo creates and sets these special variables:

`V_flag` The kind of menu that was selected:

V_flag	Menu Kind
0	Normal text menu item, including **Optional Menu Items** (see page IV-110) and **Multiple Menu Items** (see page IV-111).
3	"*FONT*"
6	"*LINESTYLEPOP*"

V_flag	Menu Kind
7	"*PATTERNPOP*"
8	"*MARKERPOP*"
9	"*CHARACTER*"
10	"*COLORPOP*"
13	"*COLORTABLEPOP*"

See **Specialized Menu Item Definitions** on page IV-112 for details about these special user-defined menus.

`V_value` Which menu item was selected. The value also depends on the kind of menu the item was selected from:

V_flag	V_value meaning
0	Text menu item number (the first menu item is number 1).
3	Font menu item number (use S_Value, instead).
6	Line style number (0 is solid line)
7	Pattern number (1 is the first selection, a SW-NE light diagonal).
8	Marker number (1 is the first selection, the X marker).
9	Character as an integer, = char2num(S_Value). Use S_Value instead.
10	Color menu item (use V_red, V_green, and V_blue instead).
13	Color table list menu item (use S_Value instead).

`S_value` The menu item text, depending on the kind of menu it was selected from:

V_flag	S_value meaning
0	Text menu item text.
3	Font name or “default”.
6	Name of the line style menu or submenu.
7	Name of the pattern menu or submenu.
8	Name of the marker menu or submenu.
9	Character as string.
10	Name of the color menu or submenu.
13	Color table name.

In the case of **Specialized Menu Item Definitions** (see page IV-112), S_value will be the title of the menu or submenu, etc.

`V_red`, `V_green`, `V_blue`

If a user-defined color menu ("*COLORPOP*" menu item) was chosen then these values hold the red, green, and blue values of the selected color. The values range from 0 to 65535.

Will be 0 if the last user-defined menu selection was not a color menu selection.

`S_graphName`, `S_traceName`

These are set only when any user-defined menu is chosen from a graph’s trace contextual menu. (Menu “TracePopup” or Menu “AllTracesPopup” definitions).

Initially `""` until a user-defined menu selection was made from one of these contextual menus, these are not reset for each user-defined menu selection.

S_graphName is the full host-child specification for the graph. If the graph is embedded into a host window, S_graphName might be something like "Panel0#G0". See **Subwindow Syntax** on page III-95.

S_traceName is name of the trace that was selected by the trace contextual menu, or "" if the AllTracesPopup menu was chosen. See **Subwindow Syntax** on page III-95.

Examples

A Multiple Menu Items menu definition:

```
Menu "Wave List", dynamic
    "Menu Item 1", <some command>
    "Menu Item 2", <some command>
    WaveList("*",";",""), DoSomethingWithWave()
End
```

If the user selects one of the (many) menu items created by the "Wave List" menu item definition, the DoSomethingWithWave user function can call GetLastUserMenuInfo to determine which wave was selected:

```
Function DoSomethingWithWave()
    GetLastUserMenuInfo
    WAVE/Z selectedWave = $S_value
    …use selectedWave for something…
End
```

A trivial user-defined color menu definition:

```
Menu "Color"
    "*COLORPOP*", DoSomethingWithColor()
End

Function DoSomethingWithColor()
    GetLastUserMenuInfo
    …do something with V_red, V_green, V_blue…
End
```

See **Specialized Menu Item Definitions** on page IV-112 for another color menu example.

A Trace contextual menu Items menu definition:

```
Menu "TracePopup", dynamic        // menu when a trace is right-clicked
    "-"                       // separator divides this from built-in menu items
    ExportTraceName(), ExportSelectedTrace()
End

Function/S ExportTraceName()
    GetLastUserMenuInfo     // only S_graphName, S_traceName are set.
    Return "Export "+S_traceName
End

Function ExportSelectedTrace()
    GetLastUserMenuInfo
    …do something with S_graphName, S_traceName…
End
```

GetMarquee

GetMarquee [**/K/W=*winName*/Z**] [***axisName*** [**, *axisName***]]

The GetMarquee operation provides a way for you to use the marquee as an input mechanism in graphs and page layout windows. It puts information about the marquee into variables.

Parameters

If you specify *axisName* (allowed only for graphs) the coordinates are in axis units. If you specify an axis that does not exist, Igor generates an error.

If you specify only one axis then Igor sets only the variables appropriate to that axis. For example, if you execute "GetMarquee left" then Igor sets the V_bottom and V_top variables but does *not* set V_left and V_right.

Flags

/K Kills the marquee. Usually you will want to kill the marquee when you call GetMarquee, so you should use the /K flag. This is modeled after what happens when you create a marquee in a graph and then choose Expand from the Marquee menu.

There may be some situations in which you want the marquee to persist. Igor also automatically kills the marquee anytime the window containing the marquee is deactivated, including when a dialog is summoned.

/W=*winName* Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

/Z No runtime error generated if the target window isn't a graph or layout, but V_flag will be zero. /Z does not prevent other kinds of problems from generating a runtime error.

Details

GetMarquee is intended to be used in procedures invoked through user menu items added to the graph Marquee menu and the layout Marquee menu.

GetMarquee sets the following variables and strings:

`V_flag`	0: There was no marquee when GetMarquee was invoked.
	1: There was a marquee when GetMarquee was invoked.
`V_left`	Marquee left coordinate.
`V_right`	Marquee right coordinate.
`V_top`	Marquee top coordinate.
`V_bottom`	Marquee bottom coordinate.
`S_marqueeWin`	Name of window containing the marquee, or `""` if no marquee. If subwindow, subwindow syntax will be used.

When called from the command line, GetMarquee sets global variables and strings in the current data folder. When called from a procedure, it sets local variables and strings.

In addition, creating, adjusting, or removing a marquee may set additional marquee global variables (see the **Marquee Globals** section, below).

The target window must be a layout or a graph. Use /Z to avoid generating a runtime-error (V_flag will be 0 if the target window was not a layout or graph).

If the target is a layout then Igor sets the variables in units of points relative to the top/left corner of the paper.

If the target is a graph then Igor sets V_left and V_right based on the specified horizontal axis. If no horizontal axis was specified, V_left and V_right are set relative to the left edge of the base window in points.

If the target is a graph then Igor sets V_bottom and V_top based on the specified vertical axis. If no vertical axis was specified, V_top and V_bottom are set relative to the top edge of the base window in points.

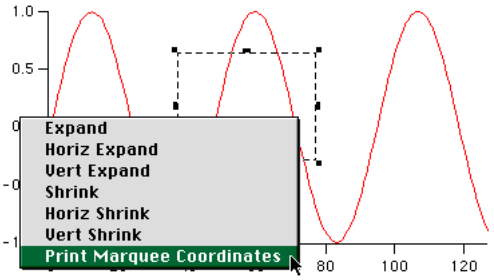
If there is no marquee when you invoke GetMarquee then Igor sets V_left, V_top, V_right, V_bottom based on the last time the marquee was active.

GetMarquee Example

```
Menu "GraphMarquee"
    "Print Marquee Coordinates", PrintMarqueeCoords()
End

Function PrintMarqueeCoords()
    GetMarquee left, bottom
    if (V_flag == 0)
        Print "There is no marquee"
    else
        printf "marquee left in bottom axis terms: %g\r", V_left
        printf "marquee right in bottom axis terms: %g\r", V_right
        printf "marquee top in left axis terms: %g\r", V_top
        printf "marquee bottom in left axis terms: %g\r", V_bottom
    endif
End
```

You can run this procedure by putting it into the procedure window, making a marquee in a graph, clicking in the marquee and choosing Print Marquee Coordinates:



The procedure calls GetMarquee to set the local marquee variables and then prints their values in the history area:

```
•PrintMarqueeCoords()
  marquee left in bottom axis terms: 32.1149
  marquee right in bottom axis terms: 64.7165
  marquee top in left axis terms: 0.724075
  marquee bottom in left axis terms: -0.131061
```

Marquee Globals

You can cause Igor to update global marquee variables whenever the user adjusts the marquee (without the need for you to invoke GetMarquee) by creating a global variable named V_marquee in the root data folder:

```
Variable/G root:V_marquee = 1     //Creates V_marquee and sets bit 0 only
```

When the user adjusts the marquee Igor checks to see if root:V_marquee exists and which bits are set, and updates (and creates if necessary) these globals:

`Variable/G root:V_left`	Marquee left coordinate.
`Variable/G root:V_right`	Marquee right coordinate.
`Variable/G root:V_top`	Marquee top coordinate.
`Variable/G root:V_bottom`	Marquee bottom coordinate.
`String/G root:S_marqueeWin`	Name of window that contains marquee, or `""` if no marquee. Set only if root:V_Marquee has bit 15 (0x8000) set.

Unlike the local variables, for graphs these global variables are never in points. Root:V_left and V_right will be axis coordinates based on the first bottom axis created for the graph (if none, then for the first top axis). The axis creation order is the same as is returned by **AxisList**. Similarly, root:V_top and root:V_bottom will be axis coordinates based on the first left axis or the first right axis.

Igor examines the global root:V_marquee for bitwise flags to decide which globals to update, and when:

root:V_marquee Bit Meaning	Bit Number	Bit Value
Update global variables for graph marquees	0	1
Update global variables for layout marquees	2	4
Update S_marqueeWin when updating global variables	15	0x8000

Marquee Globals Example

By creating the global variable root:V_marquee this way:

```
Variable/G root:V_marquee = 1 + 4 + 0x8000
```

whenever the user creates, adjusts, or removes a marquee in any graph or layout Igor will create and update the global root:V_left, etc. coordinate variables and set the global string root:S_marqueeWin to the name of the window which has the marquee in it. When the marquee is removed, root:S_marqueeWin will be set to `""`.

This mechanism does neat things by making a **ValDisplay** or **SetVariable** control depend on any of the globals. See the Marquee Demo experiment in the Examples:Feature Demos folder for an example.

You can also cause a function to run whenever the user creates, adjusts, or removes a marquee by setting up a dependency formula using **SetFormula** to bind one of the marquee globals to one of the function's input arguments:

```
Variable/G root:dependencyTarget
SetFormula root:dependencyTarget, "MyMarqueeFunction(root:S_marqueeWin)"
Function MyMarqueeFunction(marqueeWindow)
    String marqueeWindow          // this will be root:S_marqueeWin
    if( strlen(marqueeWindow) )
        NVAR V_left= root:V_left, V_right= root:V_right
        NVAR V_top= root:V_top, V_bottom= root:V_bottom
        Printf marqueeWindow + " has a marquee at: "
        Printf "%d, %d, %d, %d\r", V_left, V_right, V_top, V_bottom
    else
        Print "The marquee has disappeared."
    endif
    return 0                      // return value doesn't really matter
End
```

See Also

The **SetMarquee** and **SetFormula** operations. **Setting Bit Parameters** on page IV-12 for information about bit settings.

GetRTError

GetRTError(*flag*)

The GetRTError function returns information about the error state of Igor's user-defined function runtime execution environment.

If *flag* is 0, GetRTError returns an error code if an error has occurred or 0 if no error has occurred.

If *flag* is 1, GetRTError returns an error code if an error has occurred or 0 if no error has occurred and it clears the error state of Igor's runtime execution environment. Use this if you want to detect and handle runtime errors yourself.

If *flag* is 2, GetRTError returns the state of Igor's internal abort flag but does not clear it.

For *flag*=0 and *flag*=1, you can call **GetErrMessage** to obtain the error message associated with the returned error code, if any.

Example

```
// This illustrates how to detect and handle a runtime error
// rather than allowing it to cause Igor to abort execution.
Function Demo()
    <Call an Igor operation or a user-defined function>
    Variable err = GetRTError(0)
    if (err != 0)
        String message = GetErrMessage(err)
        Printf "Error in Demo: %s\r", message
        err = GetRTError(1)                    // Clear error state
        Print "Continuing execution"
    endif
    <Call an Igor operation or a user-defined function>
End
```

See also

The **GetErrMessage** and **GetRTErrMessage** functions.

GetRTErrMessage

GetRTErrMessage()

In a user function, GetRTErrMessage returns a string containing the name of the operation that caused the error, a semicolon, and an error message explaining the cause of the error. This is the same information that appears in the alert dialog displayed. If no error has occurred, the string will be of zero length. GetRTErrMessage must be called before the error is cleared by calling GetRTError with a nonzero argument.

See also

The **GetRTError** and **GetErrMessage** functions.

GetRTStackInfo

GetRTStackInfo(*selector*)

The GetRTStackInfo function returns information about "runtime stack" (the chain of macros and functions that are executing).

Details

If *selector* is 0, GetRTStackInfo returns a semicolon-separated list of the macros and procedures that are executing. This list is the same you would see in the debugger's stack list.

The currently executing macro or function is the last item in the list, the macro or function that started execution is the first item in the list.

If *selector* is 1, it returns the name of the currently executing function or macro.

If *selector* is 2, it returns the name of the calling function or macro.

If *selector* is 3, GetRTStackInfo returns a semicolon-separated list of routine names, procedure file names and line numbers. This is intended for advanced debugging by advanced programmers only.

For example, if RoutineA in procedure file ProcA.ipf calls RoutineB in procedure file ProcB.ipf, and RoutineB calls GetRTStackInfo(3), it will return:

```
RoutineA,ProcA.ipf,7;RoutineB,ProcB.ipf,12;
```

The numbers 7 and 12 would be the actual numbers of the lines that were executing in each routine. Line numbers are zero-based.

GetRTStackInfo does not work correctly with string macros executed via the Execute operation.

In future versions of Igor, *selector* may request other kinds of information.

Examples

```
Function Called()
   Print "Called by " + GetRTStackInfo(2) + "()"
   Print "Routines in calling chain: " + GetRTStackInfo(0)
End

Function Calling()
   Called()
End

Macro StartItUp()
   Calling()
End
```

Executing on the Command line:

```
•StartItUp()
  Called by Calling()
  Routines in calling chain: StartItUp;Calling;Called;
```

See Also

StringFromList, **ItemsInList**, and **GetRTError** functions. **The Stack and Variables Lists** on page IV-187.

GetScrapText

GetScrapText()

The GetScrapText function returns a string containing any plain text on the Clipboard (aka "scrap"). This is the text that would be pasted into a text document if you used Paste in the Edit menu.

See Also

The **PutScrapText** and **LoadPICT** operations.

GetSelection

GetSelection *winType, winName, bitflags*

The GetSelection operation returns information about the current selection in the specified window.

Parameters

winType is one of the following keywords:

```
graph, panel, table, layout, notebook, procedure
```

winName is the name of a window of the specified type.

When identifying a subwindow with winName, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

If *winType* is procedure then *winName* is actually a procedure window title inside a $"" wrapper, such as:

```
GetSelection procedure $"DemoLoader.ipf", 3
```

bitflags is a bitwise parameter that is used in different ways for different window types, as described in **Details**. You should use 0 for undefined bits. **Setting Bit Parameters** on page IV-12 for further details about bit settings.

Details

For all window types, GetSelection sets V_flag:

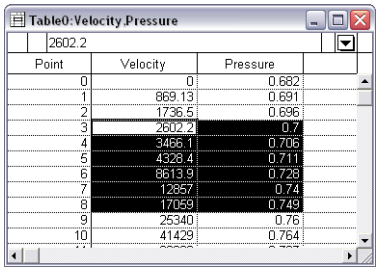
`V_flag`	0:	No selection when GetSelection was invoked.
	1:	There was a selection when GetSelection was invoked.

Here is a description of what GetSelection does for each window type:

winType	*bitFlags*	**Action**
`graph`		Does nothing.
`panel`		Does nothing.
`table`	1	Sets V_startRow, V_startCol, V_endRow, and V_endCol based on the selected cells in the table. The top/left cell, not including the Point column, is (0, 0).
	2	Sets S_selection to a semicolon-separated list of column names.
	4	Sets S_dataFolder to a semicolon-separated list of data folders, one for each column.
`layout`	2	Sets S_selection to a semicolon separated list of selected objects in the layout layer (not any drawing layers). S_selection will be `""` if no objects are selected.
`notebook`	1	Sets V_startParagraph, V_startPos, V_endParagraph, and V_endPos based on the selected text in the notebook.
	2	Sets S_selection to the selected text.
`procedure`	1	Sets V_startParagraph, V_startPos, V_endParagraph, V_endPos based on the selected text in the procedure window.
	2	Sets S_selection to the selected text.

Examples

Make a table named “Table0” with some columns, and select some combination of rows and columns:



and execute these commands in a procedure or in the command line:

```
GetSelection table, Table0, 3
Print V_flag, V_startRow, V_startCol, V_endRow, V_endCol
Print S_selection
```

This will print the following in the history area:

```
  1   3   0   8   1
  Velocity.d;Pressure.d;
```

GetUserData

GetUserData(*winName, objID, userdataName*)

The GetUserData function returns a string containing the user data for a window or subwindow. The return string will be empty if no user data exists.

Parameters

winName may specify a window or subwindow name. Use "" for the top window.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

objID is a string specifying the name of a control or graph trace. Use "" for a window or subwindow.

userdataName is the name of the user data or "" for the default unnamed user data.

See Also

The **ControlInfo**, **GetWindow**, and **SetWindow** operations.

GetWavesDataFolder

GetWavesDataFolder(*waveName, kind*)

The GetWavesDataFolder function returns a string containing the name of a data folder containing the wave named by *waveName*. Variations on the theme are selected by *kind*.

The most common use for this is in a procedure, when you want to create a wave or a global variable in the data folder containing a wave passed as a parameter.

For Igor Pro 6.1 or later, **GetWavesDataFolderDFR** is preferred.

Details

kind	GetWavesDataFolder Returns
0	Only the name of the data folder containing *waveName*.
1	Full path of data folder containing *waveName*, without wave name.
2	Full path of data folder containing *waveName*, including possibly quoted wave name.
3	Partial path from current data folder to the data folder containing *waveName*.
4	Partial path including possibly quoted wave name.

Kinds 2 and 4 are especially useful in creating command strings to be passed to **Execute**.

Examples

```
Function DuplicateWaveInDataFolder(w)
   Wave w
   String dfSav = GetDataFolder(1)
   SetDataFolder GetWavesDataFolder(w,1)
   Duplicate/O w, $(NameOfWave(w) + "_2")
   SetDataFolder dfSav
End
```

See Also

Chapter II-8, **Data Folders**.

GetWavesDataFolderDFR

GetWavesDataFolderDFR(*waveName*)

The GetWavesDataFolderDFR function returns a data folder reference for the data folder containing the specified wave.

Requires Igor Pro 6.1 or later.

GetWavesDataFolderDFR is the same as GetWavesDataFolder except that it returns a data folder reference instead of a string containing a path.

See Also
Chapter II-8, **Data Folders** and **Data Folder References** on page IV-61.

GetWindow

GetWindow [/Z] *winName, keyword*

The GetWindow operation provides information about the named window or subwindow. Information is returned in variables, strings, and waves.

Parameters

winName can be the name of graph, table, panel, page layout, notebook, or any subwindow. It can also be the title of a procedure window or one of these four special keywords:

kwTopWin	Specifies the topmost graph, table, panel, page layout, or notebook window.
kwCmdHist	Specifies the command history window.
kwFrameOuter	Specifies the "frame" or "application" window that Igor Pro has only under Windows. This is the window that contains Igor's menus and status bar.
kwFrameInner	Specifies the inside of the same "frame" window under Windows. This is the window that all other Igor windows are inside.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Only one of the following keywords may follow *winName*. The keyword chosen determines the information stored in the output variables:

active	Sets V_Value to 1 if the window is active or to 0 otherwise. Active usually means the window is the frontmost window.
activeSW	Stores the window "path" of currently active subwindow in S_Value. See **Subwindow Syntax** on page III-95 for details on the window hierarchy.
exterior	Sets V_value to 1 if the window is an exterior panel window or to 0 otherwise. Useful for window hook functions that must work for both regular windows and exterior panel windows, since exterior panels use their own hook function.
gsize	Reads graph outer dimensions into V_left, V_right, V_top, and V_bottom in local coordinates. This includes axes but not the tool bar, control bar, or info panel. Dimensions are in points.
gsizeDC	Same as gsize but dimensions are in device coordinates (pixels).
hide	Sets V_Value bit 0 if window or subwindow is hidden. Sets bit 1 if the host window is minimized.
hook	Copies name of window hook function to S_value. See **Unnamed Window Hook Functions** on page IV-271.
hook(*hName*)	For the given named hook *hName*, copies name of window hook function to S_value. See **Named Window Hook Functions** on page IV-265.
logicalpapersize	Returns logical paper size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points. If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page. V_left and V_top are 0 and correspond to the left top corner of the physical page. On the Macintosh, using a Scale of 50% multiplies all of these dimensions by 2.
logicalprintablesize	Returns logical printable size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points. If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page minus the margins. V_left and V_top are the number of points from the left top corner of the physical page to the left top corner of the printable area of page. On the Macintosh, using a page setup scale of 50% multiplies all of these dimensions by 2.
maximize	Sets V_Value to 1 if the window is maximized, 0 otherwise. On Macintosh, V_Value is always 0.
needUpdate	Sets V_Value to 1 if window or subwindow is marked as needing an update.

note	Copies window note to S_value.
psize	Reads graph plot area dimensions (where the traces are) into V_left, V_right, V_top, and V_bottom in local coordinates. Dimensions are in points.
psizeDC	Same as psize but dimensions are in device coordinates (pixels).
title	Gets the title (set by as *titleStr* with NewPanel, Display, etc., or by the Window Control dialog) and puts it into S_value. S_value is set to "" if *winName* specifies a subwindow. See also the wtitle keyword, below.
userdata	Returns the primary (unnamed) user data for a window in S_value. Use **GetUserData** to obtain any named user data.
wavelist	Creates a three-column text wave called W_WaveList containing a list of waves used in the graph in *winName*. Each wave occupies one row in W_WaveList. This list includes all waves that can be in a graph, including the data waves for contour plots and images.
wsize	Reads window dimensions into V_left, V_right, V_top, and V_bottom in points from the top left of the screen. For subwindows, values are local coordinates in the host.
wsizeDC	Same as wsize but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle.
wsizeOuter	Reads window dimensions into V_left, V_right, V_top, and V_bottom in points from the top left of the screen. Dimensions are for the entire window including any frame and title bar. For subwindows, values are for the host window.
wsizeOuterDC	Same as wsizeOuter but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle, so V_top will be negative for a window with a title bar. V_left will be negative for windows with a frame; windows on Macintosh OS X have no frame, so V_left will be zero.
wsizeRM	Generally the same as wsize, but these are the coordinates that would actually be used by a recreation macro except that the coordinates are in points even if the window is a panel. Also, if the window is minimized or maximized, the coordinates represent the window's restored location.
wtitle	Gets the actual window title displayed in the window's title bar, regardless of whether it was set by the user (see the title keyword above) or is the default title created by Igor, and puts it into S_value. S_value is set to "" if winName specifies a subwindow. If winName is kwFrameOuter or kwFrameInner, on Macintosh S_Value is set to the name of the Igor application. On Windows it is set to the full title of the application as seen on the frame's window, which can be altered using DoWindow/T kwFrame.

Flags

/Z	Suppresses error if, for instance, *winName* doesn't name an existing window. V_flag is set to zero if no error occurred or to a non-zero error code.

Details

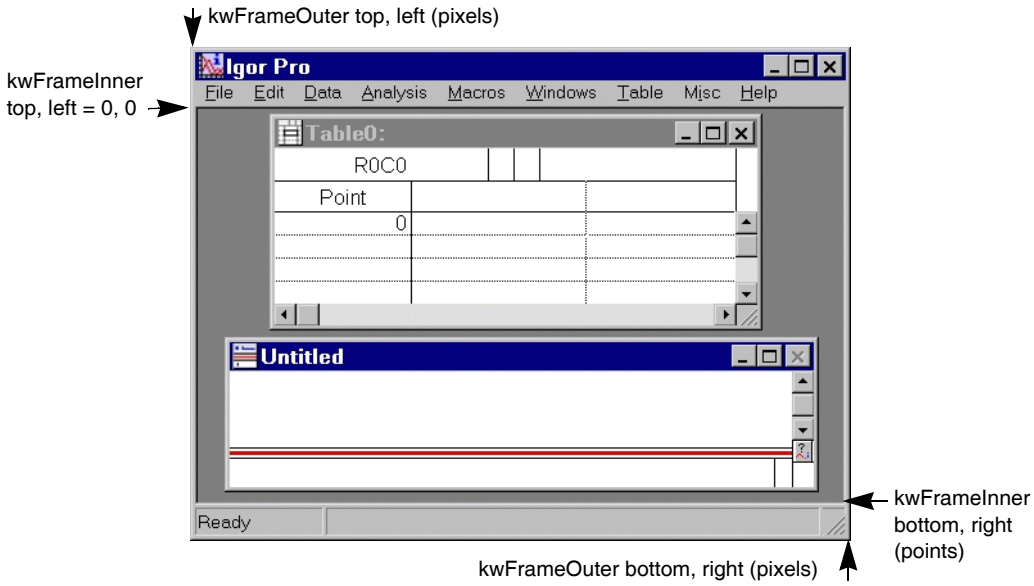
The wsize parameter is appropriate for all windows.

The gsize, psize, and wavelist parameters are appropriate only for graph windows.

The logicalpapersize and logicalprintablesize parameters are appropriate for all printable windows (not panels).

kwCmdHist, kwFrameInner, and kwFrameOuter may be used with only the wsize keyword.

On Windows computers, kwFrameInner and kwFrameOuter return coordinates into V_left, V_right, V_top, and V_bottom. On the Macintosh, they always return 0 (because Igor has no frame on the Macintosh).



kwFrameOuter coordinates are the location of the outer edges of Igor's application window, expressed in screen (pixel) coordinates suitable for use with `MoveWindow/F` to restore, minimize, or maximize the Igor application window.

If Igor is currently minimized, kwFrameOuter returns 0 for all values. If maximized, it returns 2 for all values. Otherwise, the screen (pixel) coordinates of the frame are returned in V_left, V_right, V_top, and V_bottom. This is consistent with `MoveWindow/F`.

kwFrameInner coordinates, however, are the location of the inner edges of the application window, expressed in Igor window coordinates (points) suitable for positioning graphs and other windows with **MoveWindow**.

If Igor is currently minimized, kwFrameInner returns the inner frame coordinates Igor would have if Igor were "restored" with `MoveWindow/F 1,1,1,1`.

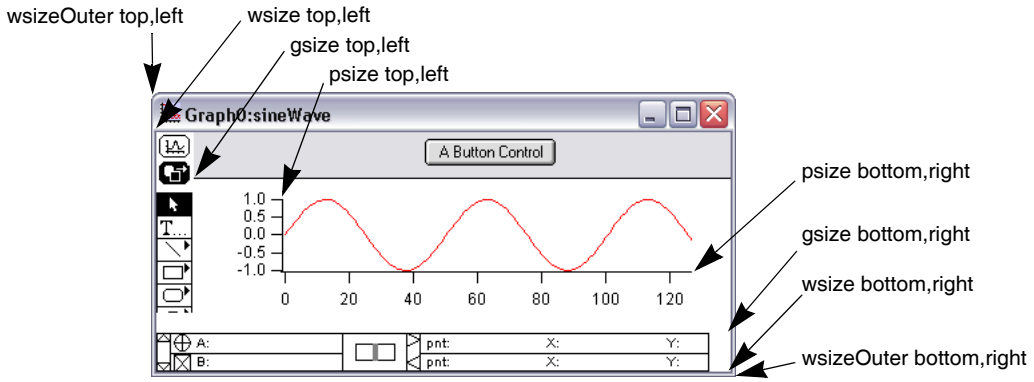
V_left and V_top will always both be 0, and V_Bottom and V_Right will be the maximum visible (or potentially visible) window (not screen) coordinates in points.

winName can be the title of a procedure window. If the title contains spaces, use:

```
GetWindow $"Title With Spaces" wsize
```

However, if another window has a name which matches the given procedure window title, that window's properties are returned instead of the procedure window.

"Local coordinates" are relative to the top left of the graph area, regardless of where that is on the screen or within the graph window. All dimensions are reported in units of points (1/72 inch) regardless of screen resolution. On the Macintosh, this is the same as screen pixels.



The format of W_WaveList, created with the wavelist keyword, is as follows:

Column 1	Column 2	Column 3
Wave name	partial path to the wave	special ID number

The wave name in column 1 is simply the name of the wave with no path. It may be the same as other waves in the list, if there are waves from different data folders.

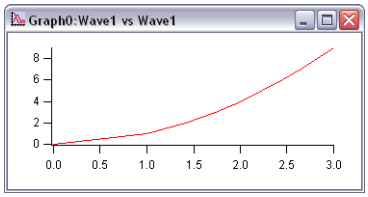
The partial path in column 2 includes the wave name and can be used with the $ operator to get access to the wave.

The special ID number in column 3 has the format ##<number>##. A version of the recreation macro for the graph can be generated that uses these ID numbers instead of wave names (see the **WinRecreation** function). This makes it relatively easy to find every occurrence of a particular wave using a function like **strsearch**.

For instance, executing these commands:

```
NewDataFolder/S Folder1
Make/N=10 Wave1=x
SetDataFolder ::
NewDataFolder/S Folder2
Make/N=10 Wave1=sqrt(x)
SetDataFolder ::
Display :Folder1:wave1 vs :Folder2:wave1
```

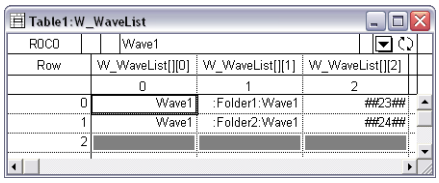
Makes a graph similar to this:



Executing these commands:

```
GetWindow kwTopWin, wavelist
Edit W_WaveList
```

makes a table similar to this:



Examples

```
// These commands draw a red foreground rectangle framing
// the printable area of a page layout window.
GetWindow Layout0 logicalpapersize
DoWindow/F Layout0
SetDrawLayer/K userFront
SetDrawEnv linefgc=(65535,0,0), fillpat=0         // Transparent fill
DrawRect V_left+1, V_top+1, V_right-1, V_bottom-1

// These commands demonstrate the difference between title and wtitle.
Make/O data=x
Display/N=MyGraph data
GetWindow MyGraph title;Print S_Value             // Prints nothing (S_Value = "")
GetWindow MyGraph wtitle;Print S_Value            // Prints "MyGraph:data"
DoWindow/T MyGraph, "My Title for My Graph"
GetWindow MyGraph title;Print S_Value             // Prints "My Title for My Graph"
GetWindow MyGraph wtitle;Print S_Value            // Prints "My Title for My Graph"
```

The **IgorInfo** function.

gnoise

gnoise(*num* [, *RNG*])

The gnoise function returns a random value from a Gaussian distribution such that the standard deviation of an infinite number of such values would be *num*.

The random number generator is initialized using the system clock when you start Igor, virtually guaranteeing that you will never get the same sequence twice. If you want repeatable "random" numbers, use **SetRandomSeed**.

The Gaussian distribution is achieved using a Box-Muller transformation of uniform random numbers.

The optional parameter *RNG* selects one of two different pseudo-random number generators used to create the uniformly-distributed random numbers used as the input to the Box-Muller transformation. If omitted, the default is 1. The *RNG*'s are:

RNG	Description
1	Linear Congruential generator by L'Ecuyer with added Bayes-Durham shuffle. The algorithm is described in *Numerical Recipes* (2nd edition) as the function `ran2()`. This RNG has nearly 2^{32} distinct values and the sequence of random numbers has a period in excess of 10^{18}.
2	Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of 2^{19937}-1.

Graph

Graph

Graph is a procedure subtype keyword that identifies a macro as being a graph recreation macro. It is automatically used when Igor creates a window recreation macro for a graph. See **Procedure Subtypes** on page IV-179 and **Saving and Recreating Graphs** on page II-300 for details.

GraphMarquee

GraphMarquee

GraphMarquee is a procedure subtype keyword that puts the name of the procedure in the graph Marquee menu. See **Marquee Menu as Input Device** on page IV-140 for details.

GraphNormal

GraphNormal [**/W=*winName***]

The GraphNormal operation returns the target or named graph to the normal mode, exiting any drawing mode that it may be in.

You would usually enter normal mode by choosing ShowTools from the Graph menu and clicking the crosshair tool.

Flags

/W=winName Reverts the named graph window. This must be the first flag specified when used in a Proc or Macro or on the command line.

See Also

The **GraphWaveDraw** and **GraphWaveEdit** operations.

GraphStyle

GraphStyle

GraphStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Graph dialog and in the Graph Macros menu. See **Graph Style Macros** on page II-300 for details.

GraphWaveDraw

GraphWaveDraw [***flags***] [***yWaveName, xWaveName***]

The GraphWaveDraw operation initiates drawing a curve composed of *yWaveName* vs *xWaveName* in the target or named graph. The user draws the curve using the mouse, and the values are stored in a pair of waves as XY data.

Normally, you would initiate drawing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using GraphWaveDraw.

Parameters

yWaveName and *xWaveName* will contain the y and x values of the curve drawn by the user with the mouse.

If *yWaveName* and *xWaveName* do not already exist, they are created with two points which are initially set to NaN (Not a Number) and appended to the target.

If *yWaveName* and *xWaveName* already exist, an error is generated unless the /O (overwrite) flag is present. If /O is present, the waves are re-created — with two points which are initially set to NaN — and appended to the target if they are not already in it.

If *yWaveName* and *xWaveName* are omitted then waves called W_YPoly*n* and W_XPoly*n* are created with two points set to NaN and appended to the target (*n* is some digit, so Igor might create a wave named W_YPoly0, for example).

Flags

/F[=*f*]	Initiates freehand drawing. In normal drawing, you click where you want a data point. In freehand drawing, you click once and then draw with the mouse button held down. If present, *f* specifies the smoothing factor. Max value is 8 (which is really slow), min value is 0 (default). The drawing tools use a value of 3 which is the recommended value.
/L/R/B/T	Specifies which axes to use (Left, Right, Bottom, Top). Bottom and Left axes are used by default. Can specify free axes using /L=*axis name* type notation. See **AppendToGraph** for details. If necessary, the specified axes will be created. If an axis is created its range is set to -1 to 1.
/M	Specifies that the curve being edited must be monotonic in the X dimension. The user is not allowed drag points so that they cross horizontally.
/O	Overwrites *yWaveName* and *xWaveName* if they already exist.
/W=*winName*	Draws in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

Once drawing starts no other user actions are allowed.

In normal mode, drawing stops when you double-click or when you click the first point (in which case the last point is set equal to the first point). When drawing finishes, the edit mode is entered.

In freehand mode, drawing stops when the mouse is released or when 10000 points have been drawn.

If /O is used and the waves are already on the graph then the first instance on the graph will be used even if they use a different pair of axes than specified.

See Also

The **GraphNormal**, **GraphWaveEdit** and **DrawAction** operations.

GraphWaveEdit

GraphWaveEdit [***flags***] ***traceName***

The GraphWaveEdit operation initiates editing a wave trace in a graph. The wave trace must already be in the graph.

Normally, you would initiate editing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using GraphWaveEdit.

Parameters

traceName is a wave name, optionally followed by the # character and an instance number: "myWave#1" is the *second* instance of myWave appended to the graph ("myWave" is the first).

If *traceName* is omitted then you get to pick the wave trace to edit by clicking it.

Flags

/M	Specifies that the edited trace must be monotonic in the X dimension. You cannot drag points so that they cross horizontally.
/NI	Suppresses automatic new point insertion when clicking between points.
/T=*t*	Sets the trace mode. *t*=0: Lines and small square markers (default). *t*=1: User settings unchanged.
/W=*winName*	Edits traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The GraphWaveEdit operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

See Also

The **GraphNormal**, **GraphWaveDraw** and **DrawAction** operations.

Grep

Grep [***flags***][***srcFileStr***][***srcTextWaveName***][**as** [***destFileOrFolderStr***] [***destTextWaveName***]]

The Grep operation copies lines matching a search expression from a file on disk, the Clipboard, or rows from a text wave to a new or existing file, an existing text wave, the History area, the Clipboard, or to S_value as a string list.

Source Parameters

The optional *srcFileStr* can be

- The full path to the file to copy lines from (in which case /P is not needed).
- The partial path relative to the folder associated with *pathName.*
- The name of a file in the folder associated with *pathName.*
- "Clipboard" to read lines of text from the Clipboard (in which case /P is ignored).

If Igor can not determine the location of the source file from *srcFileStr* and *pathName*, it displays a dialog allowing you to specify the source file.

The optional *srcTextWaveName* is the name or path to a text wave.

Only one of *srcFileStr* or *srcTextWaveName* may be specified. If neither is specified then an Open File dialog is presented allowing you to specify a source file.

Destination Parameters

The optional *destFileOrFolderStr* can be

- The name of (or path to) an existing folder when /D is specified.

- The name of (or path to) a possibly existing file.
- "Clipboard", in which case the matching lines are copied to the Clipboard (and /P and /D are ignored). The text can be retrieved with the **GetScrapText** function.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with *pathName*.

If /D is specified, the source file is created inside the folder using the source file name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

The optional *destTextWaveName* is the name or path to an existing text wave. It may be the same wave as *srcTextWaveName*.

Only one of *destFileOrFolderStr* or *destTextWaveName* may be specified.

If no destination file or text wave is specified then matching lines are printed in the history area, unless the /Q flag is specified, in which case the matching lines aren't printed or copied anywhere (though the output variables are still set).

Use /LIST to set S_value to a string list containing the matching lines or rows.

Use /INDX to create a wave W_index containing the zero-based row or line number where matches were found.

Parameter Details

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-398 for details on forming the path.

Folder paths should not end with single path separators. See **MoveFolder**'s Details section.

Flags

/A
: Appends matching lines to the destination file, creating it if necessary, appends text to the Clipboard if the *destFileOrFolderStr* is "Clipboard", or appends rows to the destination text wave. Has no effect on output to the History area.

/D
: Interprets *destFileOrFolderStr* as the name of (or path to) an existing folder (or directory). Without /D, *destFileOrFolderStr* is the name of (or path to) a file. It is ignored if the destination is a text wave, the Clipboard, or the History area.

: If *destFileOrFolderStr* is not a full path to a folder, it is relative to the folder associated with *pathName*.

/DCOL={*colNum*}
: Useful only when the destination is *destTextWaveName*.

: Copies matching lines of text from the source file, Clipboard, or *srcTextWaveName* to column *colNum* of *destTextWaveName*, with any terminator characters removed.

: The default when the source is a file or the Clipboard is `/DCOL={0}`, which copies matching lines into the first column of *destTextWaveName*.

: The default when the source is *srcTextWaveName* is to copy each column of a matched row to the corresponding column in *destTextWaveName*.

: /DCOL must be used with the /A flag, otherwise the destination wave will have only 1 column.

/DCOL={[*colNum*] [, *delimStr*], …}
: Useful only when the source is *srcTextWaveName* and the destination is a file, the Clipboard, History area, or S_value.

: Copies multiple columns in any order from matching rows of *srcTextWaveName* to the destination file, Clipboard, History area, or S_value.

: Construct the line by appending the contents of the numbered column and the *delimStr* parameters in the order specified. The output line is terminated as described in **Line Termination**.

/E=*regExprStr*
: Specifies the Perl-compatible regular expression string. A line must match the regular expression to be copied to the output file. See **Regular Expressions**.

: *Multiple /E flags may be specified*, in which case a line is copied only if it matches every regular expression.

/E={*regExprStr*, *reverse*}

Specifies the Perl-compatible regular expression string, *regExprStr*, for which the sense of the match can be changed by *reverse*.

reverse=1: Matching expressions are taken to **not** match, and vice versa. For example, use `/E={"CheckBox",1}` to list all lines that do not contain "CheckBox".

reverse=0: Same as /E=*regExptrStr*.

/GCOL=*grepCol*

Greps the specified column of *srcTextWaveName*, which is a two-dimensional text wave. The default search is on the first column (`grepCol=0`). Use `grepCol=-1` to match against any column of *srcTextWaveName*.

Does not apply if the source is a file or Clipboard.

/I

Requires interactive searching even if *srcFileStr* and *destFileOrFolderStr* are specified and if the source file exists. Same as /I=3.

/I=*i*

Specifies the degree of file search interactivity with the user.

i =0: Default; interactive only if *srcFileStr* is not specified or if the source file is missing. Same as if /I were not specified.

Note: This is different behavior than other commands such as **CopyFile**.

i =1: Interactive even if *srcFileStr* is specified and the source file exists.

i =2: Interactive even if *destFileOrFolderStr* is specified.

i =3: Interactive even if *srcFileStr* is specified, the source file exists, and *destFileOrFolderStr* is specified.

/INDX

Creates in the current data folder an output wave W_Index containing the line numbers (or row numbers) where matching lines were found. If this is the only output you need, also use the /Q flag.

/LIST[=*listSepStr*]

Creates an output string variable S_value containing a semicolon-separated list of the matching lines. If *listSepStr* is specified, then it is used to separate the list items. See **StringFromList** for details on string lists. If this is the only output you need, also use the /Q flag.

/M=*messageStr*

Specifies the prompt message in any Open File dialog. If /S is not specified, then *messageStr* will be used for both the Open File and Save File dialogs.

/O

Overwrites any existing destination file.

/P=*pathName*

Specifies the folder containing the source file or the folder into which the file is copied. *pathName* is the name of an existing symbolic path.

Both *srcFileStr* and *destFileOrFolderStr* must be either simple file or folder names, or paths relative to the folder specified by *pathName*.

/Q

Prevents printing results to an output file, text wave, History, or Clipboard. Use /Q to check for a match to *regExprStr* by testing the value of V_flag, V_value, S_value (/LIST), or W_Index (/INDX) without generating any other matching line output.

Note: When using /Q neither *destFileOrFolderStr* nor *destTextWaveName* may be specified.

/S=*saveMessageStr*

Specifies the prompt message in any Save File dialog.

/T=*termcharStr*

Specifies the terminator character.

termcharStr	**Terminator**
`/T=(num2char(13))`	Carriage return (CR, ASCII code 13).
`/T=(num2char(10))`	Linefeed (LF, ASCII code 10).
`/T=";"`	Semicolon.
`/T=""`	Null (ASCII code 0).

See **Line Termination** for the default behavior of the terminator character.

/Z[=*z*]

Prevents aborting of procedure execution when attempting to copy to a nonexistent file. Use /Z if you want to handle this case in your procedures rather than having execution abort.

z=0: Same as no /Z at all.

z=1: Copy file only if it exists. /Z alone is the same as /Z=1.

z=2: Copy file if it exists and display a dialog if it does not exist.

Line Termination

Line termination applies mostly to source and destination files. (The Clipboard and history area delimit lines with CR, and text waves have no line terminators.)

If /T is omitted, Grep will break file lines on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.)

Grep reads whichever of these terminator(s) appear in the source file and use them to write lines to any output file.

The terminator(s) are removed before the line is matched against the regular expression.

For lines that match *regExprStr*, terminator(s) in the input file are transferred to the output file unless the output is the Clipboard or history area, in which case the output terminator is always only CR (like **LoadWave**). This means you can transparently handle files that use CR, LF, CRLF, or LFCR as the terminator, and omitting /T will be suitable for most cases.

If you use the /T flag, then Grep will terminate line-from-file reads on the specified character only and will output the specified character into any output file.

"Lines" in One-dimensional Text Waves

Grep considers each row of *srcTextWaveName* or *destTextWaveName* to be a "line" of input or output.

When the destination is a file, the Clipboard, or the History area, Grep copies all of the text in a matching row of *srcTextWaveName* to the file and terminates the line. See **Line Termination** for the rules on line terminators.

When the destination is a *destTextWaveName*, Grep simply copies all the text in a matching row to a row in *destTextWaveName*, without adding or omitting any terminators.

"Lines" and Columns in Two-Dimensional Text Waves

Grep by default *matches* against only the first column (column 0) of each row of *srcTextWaveName*. You can use the /GCOL=*grepCol* flag to specify a different column to match against. Use /GCOL=-1 to match against any column of *srcTextWaveName*.

When the source is a text wave and the destination is a file, the Clipboard, or the History area, Grep by default *copies* only the first column (column 0) to the destination.

Use the /DCOL={*colNum1, delimStr1, colNum2, delimStr2,...colNumN*} to print multiple columns (in any order) with delimiters after each column (the last column number need not be followed by a delimiter string). The output line is terminated with CR or *termcharStr* as described in **Line Termination**.

When both the source and destination are text waves and append (/A) is *not* specified, the destination text wave is redimensioned to have the same number of columns as the source text wave, and all columns of matching rows of *srcTextWaveName* are copied to *destTextWaveName*.

When both the source and destination are text waves and append /A is specified, then the number of columns in *destTextWaveName* is left unchanged, and each column of *srcTextWaveName* is copied to the corresponding column of *destTextWaveName*.

If the destination is a text wave and the source is a file or the Clipboard, each line (without the terminator) is copied to the first column of the destination text wave, or use /DCOL={*destColNum*} to put the text into a different column.

Output Variables

The Grep operation returns information in the following variables. When running in a user-defined function these are created as local variables. Otherwise they are created as global variables in the current data folder.

V_flag	0:	Output successfully generated.
	-1:	User cancelled either the Open File or Save File dialogs.
	Other:	An error occurred, such as the specified file does not exist.
V_value	The number of input lines that matched the regular expression.	
V_startParagraph	Zero-based line number into the file or Clipboard (or the row number of a source text wave) where the first regular expression was matched. Also see the **/INDX** flag.	

S_fileName	Full path to the source file, the source text wave, or "Clipboard". If an error occurred or if the user cancelled, it is an empty string.
S_path	Full path to the destination file or destination text wave.
	"Clipboard": If *destFileOrFolderStr* was the Clipboard.
	"History": If the output was printed to the History window.
	"": If an error occurred, if the user cancelled, or if /Q was specified.
S_value	Contains matching lines as a string list only if /LIST is specified.

Regular Expressions

A regular expression is a pattern that is matched against a subject string from left to right. Most characters stand for themselves in a pattern, and match the corresponding characters in the "subject".

In the case of Grep, the "subject" is each line of the source file or Clipboard, or each row in the source text wave.

The regular expression syntax supported by Grep, **GrepList**, and **GrepString** is based on the "Perl-Compatible Regular Expression" (PCRE) library.

The syntax is similar to regular expressions supported by various UNIX and POSIX `egrep(1)` commands. See **Regular Expressions** on page IV-152 for more details. Igor's implementation does not support the Unicode (UTF-8) portion of PCRE.

As a trivial example, the pattern "Fred" as specified here:

```
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
```

matches lines that contain the string "Fred" anywhere on the line.

Character matching is *case-sensitive* by default, similar to strsearch. Prepend the Perl 5 modifier `(?i)` to match upper and lower-case versions of "Fred":

```
// Copy lines that contain "Fred", "fred", "FRED", "fREd", etc
Grep/P=myPath/E="(?i)fred" "afile.txt" as "AnyFredFile.txt"
```

To copy lines that do *not* match the regular expression, set the /E flag's reverse parameter:

```
// Copy lines that do NOT contain "Fred", "fred", "fREd", etc.
Grep/P=myPath/E={"(?i)fred",1} "afile.txt" as "NotFredFile.txt"
```

Note: Igor doesn't use the opening and closing regular expression delimiters that UNIX grep or Perl use: they would have used `"/Fred/"` and `"/(?i)fred/"`.

Regular expressions in Igor support the expected metacharacters and character classes that make the whole grep paradigm so useful. For example:

```
// Copy lines that START with a space or tab character
Grep/P=myPath/E="^[ \\t]" "afile.txt" as "LeadingTabsFile.txt"
```

For a complete description of regular expressions, see **Regular Expressions** on page IV-152, especially for a description of the many uses of the regular expression backslash character (see **Backslash in Regular Expressions** on page IV-155).

Note: Because Igor Pro also has special uses for backslash (see **Escape Characters in Strings** on page IV-13), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes identifies a single backslash for the Grep command.

For example, to copy lines that contain "\z", the Perl pattern would be `\\z`, but the equivalent Grep expression would be `/E="\\\\z"`.

See **Backslash in Regular Expressions** on page IV-155 for a more complete description of backslash behavior in Igor Pro.

Examples

```
// Copy lines in afile.txt containing "Fred" (case sensitive)
// to an output file named "AnyFredFile.txt" in the same directory.
Grep/P=myPath/E="Fred" "afile.txt" as "AnyFredFile.txt"

// Copy lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)
// to a text wave (which must exist andis overwritten):
Make/O/N=0/T outputTextWave
Grep/P=myPath/E="(?i)fred"/E="(?i)wilma" "afile.txt" as outputTextWave

// Print lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)
// to the history area
Make/O/N=0/T outputTextWave
Grep/P=myPath/E="(?i)fred"/E="(?i)wilma" "afile.txt"
```

```
// Test whether afile.txt contains the word "boondoggle", and if so,
// on which line the first occurence was found, WITHOUT creating any output.
//
// Note: the \\b sequences limit matches to a word boundary before and after
// "boondoggle", so "boondoggles" and "aboondoggle" won't match.
//
Grep/P=myPath/Q/E="(?i)\\bBoondoggle\\b" "afile.txt"
if( V_value )                       // at least one instance was found
   Print "First instance of \"boondoggle\" was found on line", V_startParagraph
endif

// Create in S_value a string list of the lines as \r - separated list items:
Grep/P=myPath/LIST="\r"/Q/E="(?i)\\bBoondoggle\\b" "afile.txt"
if( V_Value )                       // some were found
   Print S_value
endif

// Create in W_index a list of the 0-based line numbers where "boondoggle"
// or "boondoggles", etc was found in afile.txt.
Grep/P=myPath/INDX/Q/E="(?i)boondoggle" "afile.txt"
if( V_flag )          // grep succeeded, perhaps none were found; let's see where
   WAVE W_Index       // needed if in a function
   Edit W_Index       // show line numbers in a table.
endif

// (Create a string list and text wave for the following examples.)
String list= CTabList()             // "Grays;Rainbow;YellowHot;..."
Variable items= ItemsInList(list)
Make/O/T/N=(items) textWave= StringFromList(p,list)

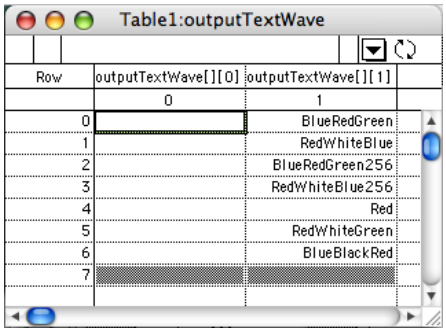
// Copy rows of textWave that contain "Red" (case sensitive)
// to the Clipboard as carriage-return separated lines.
Grep/E="Red" textWave as "Clipboard"

// Copy lines of the Clipboard that do NOT contain "Blue"
// (case in-sensitve) back to the Clipboard, overwriting what was there:
Grep/E={"(?i)blue",1} "Clipboard" as "Clipboard"

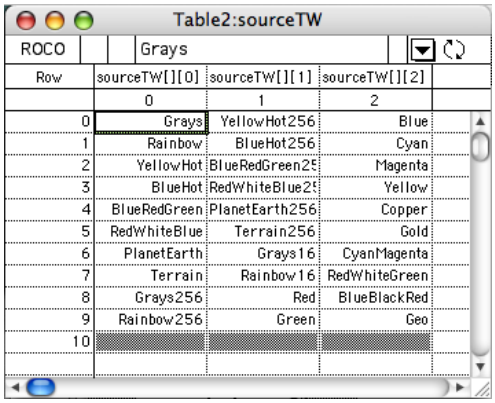
// Format matching text wave row to the history area
Grep/E=("Red")/DCOL={"prefix text --- ", 0, " --- suffix text"} textWave

// Printed output:
   prefix text --- BlueRedGreen --- suffix text
   prefix text --- RedWhiteBlue --- suffix text
   prefix text --- BlueRedGreen256 --- suffix text
   prefix text --- RedWhiteBlue256 --- suffix text
   prefix text --- Red --- suffix text
   prefix text --- RedWhiteGreen --- suffix text
   prefix text --- BlueBlackRed --- suffix text

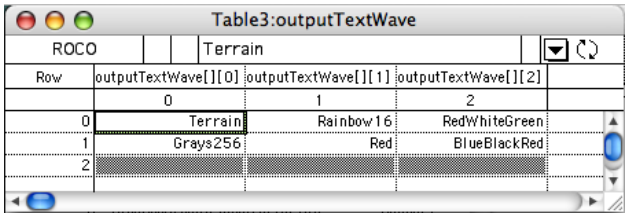
// Create a 2-column text wave whose column 1 (the second column)
// contains the matching text from the Clipboard
Make/O/N=(0,2)/T outputTextWave
// Grep with /A to preserve 2 columns of outputTextWave
Grep/A/E="Red"/GCOL=1/DCOL={1} "Clipboard" as outputTextWave
```



```
// Examples with two-dimensional source text waves
Make/O/T/N=(10, 3) sourceTW= StringFromList(p+10*q,list)
Edit sourceTW
```



```
// Copy rows of textWave that contain "Red" in column 2 to outputTextWave.
Make/O/N=0/T outputTextWave
Grep/E="Red"/GCOL=2 sourceTW as outputTextWave
Edit outputTextWave
```



```
// Format matching text wave columns to the history area.
// Match lines that contain "Red" in any column of sourceTW:
Grep/E=("Red")/GCOL=-1/DCOL={0,", ",1,", ",2} sourceTW

// Printed output:
    YellowHot, BlueRedGreen256, Magenta
    BlueHot, RedWhiteBlue256, Yellow
    BlueRedGreen, PlanetEarth256, Copper
    RedWhiteBlue, Terrain256, Gold
    Terrain, Rainbow16, RedWhiteGreen
    Grays256, Red, BlueBlackRed
```

References

The regular expression syntax supported by Grep, **GrepString**, and **GrepList** is based on the *PCRE — Perl-Compatible Regular Expression Library* by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.

Visit <`http://pcre.org/`> for more information about the PCRE library, and <`http://www.perldoc.com/`> for more about Perl regular expressions. The description of regular expressions above is taken from the PCRE documentation.

A good book on regular expressions is: Friedl, Jeffrey E. F., *Mastering Regular Expressions*, 2nd ed., 492 pp., O'Reilly Media, 2002.

See Also

Regular Expressions on page IV-152 and **Symbolic Paths** on page II-34.

SplitString, **CopyFile**, **PutScrapText**, **LoadWave** operations. The **GrepString**, **GrepList**, **stringmatch**, and **cmpstr** functions.

GrepList

`GrepList(`*`listStr`*`, `*`regExprStr`*` [,`*`reverse`*` [, `*`listSepStr`*`]])`

The GrepList function returns each list item in *listStr* that matches the regular expression *regExprStr*.

ListStr should contain items separated by the *listSepStr* character, such as in "abc;def;".

regExprStr is a regular expression such as is used by the UNIX `grep(1)` command. It is much more powerful than the wildcard syntax used for **ListMatch**. See **Regular Expressions** on page IV-152 for *regExprStr* details.

reverse is optional. If missing, it is taken to be 0. If *reverse* is nonzero then the sense of the match is reversed. For example, if *regExprStr* is `"^abc"` and *reverse* is `1`, then all list items that do not start with "abc" are returned.

listSepStr is optional; the default is `";"`. In order to specify *listSepStr*, you must precede it with reverse.

Examples

To list ColorTables containing "Red", "red", or "RED" (etc.):

```
Print GrepList(CTabList(),"(?i)red")        // case-insensitive matching
```

To list window recreation commands starting with "\tCursor":

```
Print GrepList(WinRecreation("Graph0", 0), "^\tCursor", 0 , "\r")
```

See Also

Regular Expressions on page IV-152.

ListMatch, **StringFromList**, and **WhichListItem** functions and the **Grep** operation.

GrepString

GrepString(*string*, *regExprStr*)

The GrepString function tests *string* for a match to the regular expression *regExprStr*. Returns 1 to indicate a match, or 0 for no match.

Details

regExprStr is a regular expression such as is used by the UNIX grep(1) command. It is much more powerful than the wildcard syntax used for **stringmatch**. See **Regular Expressions** on page IV-152 for *regExprStr* details.

Character matching is case-sensitive by default, similar to **strsearch**. Prepend the Perl 5 modifier "(?i)" to match upper and lower-case text

Examples

Test for truth that the string contains at least one digit:

```
if( GrepString(str,"[0-9]+") )
```

Test for truth that the string contains at least one "abc", "Abc", "ABC", etc.:

```
if( GrepString(str,"(?i)abc") )             // case-insensitive test
```

See Also

Regular Expressions on page IV-152.

The **stringmatch**, **cmpstr**, **strsearch**, **ListMatch**, and **ReplaceString** functions and the **SplitString** and **sscanf** operations.

GridStyle

GridStyle

GridStyle is a procedure subtype keyword that puts the name of the procedure in the Grid->Style Function submenu of the mover pop-up menu in the drawing tool palette. You can have Igor automatically create a grid style function for you by choosing Save Style Function from that submenu.

GroupBox

GroupBox [**/Z**] ***ctrlName*** [***keyword* = *value*** [**, *keyword* = *value*** …]]

The GroupBox operation creates a box to surround and group related controls.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the GroupBox control to be created or changed.

The following keyword=value parameters are supported:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of `default`, `native`, or `os9`.

platform can be one of `Mac`, `Win`, or `All`.

See **DefaultGUIControls Default Fonts and Sizes** for how enclosed controls are affected by native groupbox appearance.

See **Button** for more appearance details.

disable=*d* Sets user editability of the control.

d=0: Normal.

d=1: Hide.

d=2: Draw in gray state.

fColor=(*r*,*g*,*b*) Sets color of the title text. *r*, *g*, and *b* are integers from 0 to 65535.

font="*fontName*" Sets font used for the box title, e.g., `font="Helvetica"`.

frame=*f* Sets frame mode. If 1 (default), the frame has a 3D look. If 0, then a simple gray line is used. Generally, you should not use frame=0 with a title if you want to be in accordance with human interface guidelines.

fsize=*s* Sets font size for box title.

fstyle=fs Sets the font style of the title text. *fs* is a binary coded number with each bit controlling one aspect of the font style for the tick mark labels as follows:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

labelBack=(*r*,*g*,*b*) or 0 Sets fill color for the interior. *r*, *g*, and *b* are integers from 0 to 65535. If not set, then interior is transparent. Note that if a fill color is used, draw objects can not be used because they will be covered up. Also, you will have to make sure the GroupBox is drawn before any interior controls.

pos={*left*,*top*} Sets the postion of the box in pixels.

pos+={*dx*,*dy*} Offsets the position of the box in pixels.

size={*width*,*height*} Sets box size in pixels.

userdata(*UDName*)=*UDStr*

Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

userdata(*UDName*)+=*UDStr*

Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

title=*titleStr* Sets title to *titleStr*. Use `""` for no title.

win=*winName* Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

If no title is given and the width is less than 11 or height is specified as less than 6, then a vertical or horizontal separator line will be drawn rather than a box.

Note: Like TabControls, you need to click near the top of a GroupBox to select it.

See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

GuideInfo

`GuideInfo(winNameStr, guideNameStr)`

The GuideInfo function returns a string containing a semicolon-separated list of information about the named guide line in the named host window or subwindow.

Parameters

winNameStr can be `""` to refer to the top host window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

guideNameStr is the name of the guide line for which you want information.

Details

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
NAME	Name of the guide.
WIN	Name of the window or subwindow containing the guide.
TYPE	The value associated with this keyword is either *User* or *Builtin*. A *User* type denotes a guide created by the DefineGuide operation, equivalent to dragging a new guide from an existing one.
HORIZONTAL	Either 0 for a vertical guide, or 1 for a horizontal guide.
POSITION	The position of the guide. This is the actual position relative to the left or bottom edge of the window, not the relative position specified to DefineGuide.

The following keywords will be present only for user-defined guides:

Keyword	Information Following Keyword
GUIDE1	The guide is positioned relative to GUIDE1.
GUIDE2	In some cases, the guide is positioned at a fractional position between GUIDE1 and GUIDE2. If the guide does not use GUIDE2, the value will be `""`.
RELPOSITION	The position relative to GUIDE1 (and GUIDE2 if applicable). This is the same as the *val* parameter in DefineGuide. May be a number of pixels if only GUIDE1 is used, or a fractional value if both GUIDE1 and GUIDE2 are used.

See Also

The **GuideNameList**,s **StringByKey** and **NumberByKey** functions; the **DefineGuide** operation.

GuideNameList

`GuideNameList(winNameStr, optionsStr)`

The GuideNameList function returns a string containing a semicolon-separated list of guide names from the named host window or subwindow.

Parameters

winNameStr can be "" to refer to the top host window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

optionsStr is used to further qualify the list of guides. It is a string containing keyword-value pairs separated by commas. Use "" to list all guides. Available options are:

TYPE:type
: type = BuiltIn: List only built-in guides.
: type = User: List only user-defined guides, those created by the DefineGuide operation or by manually dragging a new guide from an existing one.

HORIZONTAL:h h = 0: List only non-horizontal (that is, vertical) guides.
h = 1: List only horizontal guides.

Example

```
String list = GuideNameList("Graph0", "TYPE:Builtin,HORIZONTAL:1")
```

See Also

The **DefineGuide** operation and the **GuideInfo** function.

Hanning

Hanning *waveName* [, *waveName*]…

Note: The **WindowFunction** operation has replaced the Hanning operation.

The Hanning operation multiplies the named waves by a Hanning window (which is a raised cosine function).

You can use Hanning in preparation for performing an FFT on a wave if the wave is not an integral number of cycles long.

The Hanning operation is not multidimensional aware. See Chapter II-6, **Multidimensional Waves**, particularly **Analysis on Multidimensional Waves** on page II-110 for details.

See Also

The **WindowFunction** operation implements the Hanning window as well as other forms such as Hamming, Parzen, and Bartlet (triangle).

The **ImageWindow** operation for windowing of images.

Hash

Hash(*inputStr, method*)

The Hash function returns a message digest string for *inputStr*. The length of the resulting hash string is fixed for each algorithm.

Parameters

inputStr is a string of arbitrary length.

method is 1 to use Secure Hash Algorithm-256.

See Also

For more about the SHA-256 algorithm see: <http://en.wikipedia.org/wiki/SHA-1>.

hcsr

hcsr(*cursorName* [, *graphNameStr*])

The hcsr function returns the horizontal coordinate of the named cursor (A through J) in the coordinate system of the top (or named) graph's X axis.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

The X axis used is the one that controls the trace on which the cursor is placed.

Examples

```
Variable xAxisValueAtCursorA = hcsr(A)      // not hcsr("A")
String str="A"
Variable xA= hcsr($str,"Graph0")            // $str is a name, too
```

See Also

The **Cursor** operation and the **CsrInfo**, **pcsr**, **qcsr**, **vcsr**, **xcsr**, and **zcsr** functions.

hermite

hermite(*n*, *x*)

The hermite function returns the Hermite polynomial of order *n*:

$$H_n(x) = (-1)^n \exp(x^2)\frac{d^n}{dx^n}\exp(-x^2).$$

The first few polynomials are:

$$1$$
$$2x$$
$$4x^2 - 2$$
$$8x^3 - 12x$$

.

See Also

The **hermiteGauss** function.

hermiteGauss

hermiteGauss(*n*, *x*)

The hermiteGauss function returns the normalized Hermite polynomial of order *n*:

$$H_n(x) = \frac{1}{\sqrt{\sqrt{\pi}2^n n!}}(-1)^n \exp(x^2)\frac{d^n}{dx^n}\exp(-x^2).$$

Here the normalization was chosen such that $\int_{-\infty}^{\infty} H_n(x)H_m(x)dx = \delta_{nm}$ where δ_{nm} is the Kronecker symbol.

See Also

The **hermite** function.

HideIgorMenus

HideIgorMenus [*MenuNameStr* [, *MenuNameStr*]…

The HideIgorMenus operation hides the named built-in menus or, if none are explicitly named, hides all built-in menus in the menu bar.

The effect of HideIgorMenus is lost when a new experiment is opened. The state of HideIgorMenus is saved with the experiment.

User-defined menus are not hidden by HideIgorMenus unless attached to built-in menus and the menu definition uses the hideable keyword.

Parameters

MenuNameStr The name of an Igor menu, like “File”, “Data”, or “Graph”.

Details

The optional menu names are in English and not abbreviated. This ensures that code developed for a localized version of Igor will run on all versions.

The built-in menus that can be shown or hidden (the Help menu can be hidden only on Windows) are those that appear in the menu bar:

File	Edit	Data	Analysis	Macros	Windows	Graph
Layout	Notebook	Panel	Procedure	Table	Misc	Help

Hiding a built-in menu to which a user-defined menu is attached results in a built-in menu with only the user-defined items. For example, if this menu definition attaches items to the built-in Graph menu:

```
Menu "Graph"
    "Do My Graph Thing", ThingFunction()
End
```

Calling `HideIgorMenus "Graph"` will still leave a Graph menu showing (when a Graph is the top-most target window) with only the user-defined menu(s) in it: in this example the one "Do My Graph Thing" item.

Hiding the Macros menu hides menus created from Macro definitions like:

```
Macro MyMacro()
   Print "Hello, world."
End
```

but does not hide normal user-defined "Macros" definitions like:

```
Menu "Macros"
   "Macro 1", MyMacro(1)
End
```

You can set user-defined menus to hide and show along with built-in menus by adding the optional hideable keyword to the menu definition:

```
Menu "Graph", hideable
   "Do My Graph Thing", ThingFunction()
End
```

Then `HideIgorMenus "Graph"` will hide those items, too. If all user-defined Graph menu definitions use the hideable keyword, then no Graph menu will appear in the menu bar.

Some WaveMetrics procedures use the `hideable` keyword so that only customer-defined menus remain when HideIgorMenus is executed.

See Also

Chapter IV-5, **User-Defined Menus**.

The **ShowIgorMenus**, **DoIgorMenu**, and **SetIgorMenuMode** operations.

HideInfo

HideInfo [**/W=*winName***]

The HideInfo operation removes the info box from a graph if it was previously shown by the **ShowInfo** operation.

Flags

/W=winName Hides the info box in the named window.

See Also

The **ShowInfo** operation.

HideProcedures

HideProcedures

The HideProcedures operation hides all procedure windows without closing or killing them.

See Also

The **DisplayProcedure** and **DoWindow** operations.

HideTools

HideTools [**/A/W=*winName***]

The HideTools operation hides the tool bar in the top graph or control panel if it was previously shown by the **ShowTools** operation.

Flags

/A Sizes the window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.

/W=winName Hides the tool bar in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

See Also

The **ShowTools** operation.

HilbertTransform

HilbertTransform [**/Z**][**/O**][**/DEST=*destWave*] *srcWave***

The HilbertTransform operation computes the Hilbert transformation of *srcWave*, which is a real or complex (single or double precision) wave of 1-3 dimensions. The result of the HilbertTransform is stored in *destWave*, or in the wave W_Hilbert (1D) or M_Hilbert in the current data folder.

Flags

/DEST=*destWave*	Creates a real wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-56 for details.
/O	Overwrites *srcWave* with the transform.
/Z	No error reporting.

Details

The Hilbert transform of a function $f(x)$ is defined by:

$$F(t) = \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{f(x)}{t-x}dx .$$

Theoretically, the integral is evaluated as a Cauchy principal value. Computationally one can write the Hilbert transform as the convolution:

$$F(t) = \frac{1}{\pi t} \cdot f(t),$$

which by the convolution theorem of Fourier transforms, may be evaluated as the product of the transform of $f(x)$ with $-i$*sgn(x) where:

$$\mathrm{sgn}(x) = \begin{cases} -1 & x < 0 \\ 0 & x = 0 \\ 1 & x > 0 \end{cases} .$$

Note that the Hilbert transform of a constant is zero. If you compute the Hilbert transform in more than one dimension and one of the dimensions does not vary (is a constant), the transform will be zero (or at least numerically close to zero).

There are various definitions for the extension of the Hilbert transform to more than one dimension. In two dimensions this operation computes the transform by multiplying the 2D Fourier transform of the input by the factor (-i)sgn(x)(-i)sgn(y) and then computing the inverse Fourier Transform. A similar procedure is used when the input is 3D.

Examples

Extract the instantaneous amplitude and frequency of a narrow-band signal.

```
Make/O/N=1000 w0,amp,phase
SetScale/I x 0,50,"", w0,amp,phase
w0 = exp(-x/10)*cos(2*pi*x)
HilbertTransform /DEST=w0h w0 // w0+i*w0h is the "analytic signal", i=cmplx(0,1)
amp = sqrt(w0^2 + w0h^2)   // extract the envelope
phase = atan2(-w0h,w0)     // extract the phase [SIGN CONVENTION?]
Unwrap 2*pi, phase         // eliminate the 2*pi phase jumps
Differentiate phase /D=freq   // would have less noise if fit to a line
                              // over interior points
freq /= 2*pi               // phase = 2*pi*freq*time
Display w0,amp   // original waveform and its envelope; note boundary effects
Display freq     // instantaneous frequency estimate, with boundary effects
```

See Also

The **FFT** operation.

References

Bracewell, R., *The Fourier Transform and Its Applications*, McGraw-Hill, 1965.

Histogram

Histogram [***flags***] ***srcWaveName, destWaveName***

The Histogram operation generates a histogram of the data in *srcWaveName* and puts the result in *destWaveName*.

Flags

/A — Accumulates the histogram result with the existing values in *destWaveName* instead of replacing the existing values with the result. Assumes /B=2 unless the /B flag is present.

Note: The result will be incorrect if you also use /P.

/B=mode

mode=1: Semiauto mode that sets the bin range based on the range of the Y values in *srcWaveName*. The number of bins is determined by the number of points in *destWaveName*.

mode=2: Uses the bin range and number of bins determined by the X scaling and number of points in *destWaveName*.

mode=3: Uses Sturges' method to determine optimal number of bins and to redimension *destWaveName* as necessary. By this method `numBins=1+log2(N)`, where N is the number of data points in *srcWaveName*. The bins will be distributed so that they include the minimum and maximum values.

mode=4: Uses a method due to Scott, which determines the optimal bin width as $\texttt{binWidth=3.49*s*N}^{-1/3}$, where N is the number of data points in *srcWaveName* and s is the standard deviation of the distribution. The bins will be distributed so that they include the minimum and maximum values.

/B={*binStart*,*binWidth*,*numBins*}

Sets the histogram bins from these parameters rather than from *destWaveName*. Changes the X scaling and length of *destWaveName*.

/C — Sets the X scaling so that X values are in the centers of the bins, which is required when you do a curve fit to the histogram output. Ordinarily, wave scaling of the output wave is set with X values at the left bin edges.

/CUM — Requests a cumulative histogram in which each bin is the sum of bins to the left. The last bin will contain the total number of input data points, or, with /P, 1.0.

When used with /A, the destination wave must be the result of a histogram created with /CUM.

Note that if you use a binning mode (/B flag) that sets a bin range that does not include the entire range of the input data, then the output will not count all of input points and the last bin will not contain the total number of input points. Input points whose values fall below the left edge of the first bin or above the right edge of the last bin will not be counted.

/N — Creates a wave (W_SqrtN) containing the square root of the number of counts in each bin. This is an appropriate wave to use as a weighting wave when doing a curve fit to the histogram results.

/P — Normalizes the histogram as a probability distribution function, and shifts wave scaling so that data correspond to the bin centers.

When using the results with **Integrate**, you must use /METH=0 or 1 because the trapezoidal approximation will give an error whose magnitude depends on the distribution function starting value.

/R=(*startX*,*endX*) — Specifies the range of X values of *srcWaveName* over which the histogram is to be computed.

/R=[*startP*,*endP*] — Specifies the range of points of *srcWaveName* over which the histogram is to be computed.

/W=*weightWave* — Creates a "weighted" histogram. In this case, instead of adding a single count to the appropriate bin, the corresponding value from *weightWave* is added to the bin. *weightWave* may be any number type, and it may be complex. If it is complex, then the destination wave will be complex.

Details

You must create a destination wave before doing the histogram. If you use /B={*binStart*, *binWidth*, *numBins*}, then the initial number of data points in the wave is unimportant since the Histogram operation changes the number of points.

Only one /B and only one /R flag is allowed.

If both /A and /B flags are missing, the bin range and number of bins is calculated as if /B=1 (auto-set) had been specified.

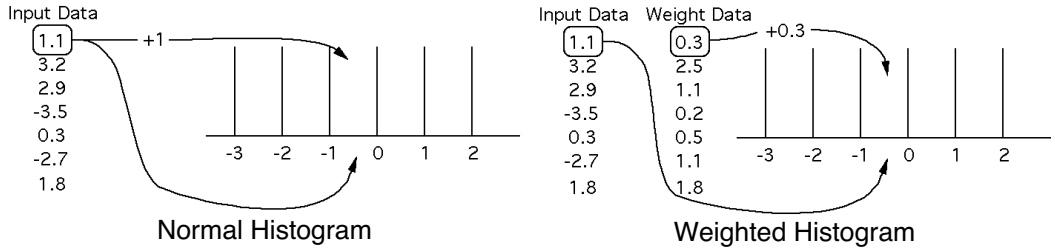
Typically, you will want to use /B={*binStart*,*binWidth*,*numBins*} for the first histogram, and /A for successive accumulations into the histogram.

The Histogram operation works on single precision floating point destination waves. If necessary, Histogram redimensions *destWaveName* to be single precision floating point. However, Histogram/A requires that *destWaveName* already be single precision floating point.

For a weighted histogram, the destination wave will be double-precision.

If you specify the range as `/R=(start)`, then the end of the range is taken as the end of *srcWaveName*.

In an ordinary histogram, input data is examined one data point at a time. The operation determines which bin a data value falls into and a single count is added to that bin. A weighted histogram works similarly, except that it adds to the bin a value from another wave in which each row corresponds to the same row in the input wave.



The Histogram operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details. In fact, the Histogram operation can be usefully applied to multidimensional waves, such as those that represent images. The /R flag will not work as expected, however.

Examples

```
// Create histogram of two sets of data.
Make/N=1000 data1=gnoise(1), data2=gnoise(1)
Make/N=1 histResult

// Sets bins, does histogram.
Histogram/B={-5,1,10} data1, histResult
Display histResult; ModifyGraph mode=5

// Accumulates into existing bins.
Histogram/A data2, histResult
```

hyperG0F1

hyperG0F1(*b*, *z*)

The hyperG0F1 function the confluent hypergeometric function

$${}_0F_1(b,z) = \sum_{i=0}^{\infty} \frac{z^i}{\Gamma(b+i)i!}$$ where $\Gamma(x)$ is the gamma function.

Note: The series evaluation may be computationally intensive. Exit the function by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*).

See Also

The **hyperG1F1**, **hyperG2F1**, and **hyperGPFQ** functions.

References

The PFQ algorithm was developed by Warren F. Perger, Atul Bhalla, and Mark Nardin.

hyperG1F1

hyperG1F1(*a*, *b*, *z*)

The hyperG1F1 function returns the confluent hypergeometric function

$${}_1F_1(a,b,z) = \sum_{n=0}^{\infty} \frac{(a)_n z^n}{(b)_n n!}$$ where $(a)_n$ is the Pochhammer symbol $(a)_n = a(a+1)\ldots(a+n-1)$.

Note: The series evaluation may be computationally intensive. Exit the function by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*).

The **hyperG0F1**, **hyperG1F1**, and **hyperGPFQ** functions.

References

The PFQ algorithm was developed by Warren F. Perger, Atul Bhalla, and Mark Nardin.

hyperGNoise

hyperGNoise(*m*, *n*, *k*)

The hyperGNoise function returns a pseudo-random value from the hypergeometric distribution whose probability distribution function is

$$f(x;m,n,k) = \frac{\binom{n}{x}\binom{m-n}{k-x}}{\binom{m}{k}}$$

where *m* is the total number of items, *n* is the number of marked items, and *k* is the number of items in a sample.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

SetRandomSeed, **StatsHyperGCDF**, and **StatsHyperGPDF**.

Chapter III-12, **Statistics** for a function and operation overview.

Noise Functions on page III-332.

hyperGPFQ

hyperGPFQ(*waveA, waveB, z*)

The hyperGPFQ function returns the generalized hypergeometric function

$${}_pF_q(\{a_1,\ldots a_p\},\{b_1,\ldots b_q\},z) = \sum_{n=0}^{\infty} \frac{(a_1)_n(a_2)_n\ldots(a_p)_n z^n}{(b_1)_n(b_2)_n\ldots(b_q)_n n!}$$

where $(a)_n$ is the Pochhammer symbol $(a)_n = a(a+1)\ldots(a+n-1)$.

Note: The series evaluation may be computationally intensive. Exit the function by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*).

References

The PFQ algorithm was developed by Warren F. Perger, Atul Bhalla, and Mark Nardin.

i

i

The i function returns the loop index of the inner most iterate loop in a macro. Not to be used in a function. iterate loops are archaic and should not be used.

if-elseif-endif

```
if ( <expression1> )
   <TRUE part 1>
elseif ( <expression2> )
   <TRUE part 2>
[…]
[else
   <FALSE part>]
endif
```

In an if-elseif-endif conditional statement, when an expression first evaluates as TRUE (nonzero), then only code corresponding to the TRUE part of that expression is executed, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then *FALSE part* is executed when present. After executing code in any TRUE part or the FALSE part, execution will next continue with any code following the if-elseif-endif statement.

See Also

If-Elseif-Endif on page IV-32 for more usage details.

if-endif

```
if ( <expression> )
   <TRUE part>
[else
   <FALSE part>]
endif
```

An if-endif conditional statement evaluates *expression*. If *expression* is TRUE (nonzero) then the code in *TRUE part* is executed, or if FALSE (zero) then the optional *FALSE part* is executed.

See Also

If-Else-Endif on page IV-31 for more usage details.s

IFFT

IFFT [***flags***] ***srcWave***

The IFFT operation calculates the Inverse Discrete Fourier Transform of *srcWave* using a multidimensional fast prime factor decomposition algorithm. This operation is the inverse of the **FFT** operation.

Output Wave Name

For compatibility with earlier versions of Igor, if you use IFFT without /ROWS or /COLS, the operation overwrites *srcWave*.

If you use the /ROWS flag, IFFT uses the default output wave name M_RowFFT and if you use the /COLS flag, IFFT uses the default output wave name M_ColFFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting *srcWave*.

Parameters

srcWave is a complex wave. The IFFT of *srcWave* is a either a real or complex wave, according to the length and flags.

Flags

/C Forces the result of the IFFT to be complex. Normally, the IFFT produces a real result unless certain special conditions are detected as described in **Details**.

/COLS Computes the 1D IFFT of 2D *srcWave* one column at a time, storing the results in the destination wave. You must specify a destination wave using the /DEST flag (no other flags are allowed). See the /ROWS flag and corresponding flags of the **FFT** operation.

/DEST=*destWave*

Specifies the output wave created by the IFFT operation.

It is an error to specify the same wave as both *srcWave* and *destWave*.

In a function, IFFT by default creates a real wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-56 for details.

/R Forces real output when, due to a power of 2 number of points, IFFT would otherwise automatically produce a complex result.

/ROWS Calculates the IFFT of only the first dimension of 2D *srcWave*. It computes the 1D FFT one row at a time. You must specify a destination wave using the /DEST flag (no other flags are allowed). See the /COLS flag and corresponding flags of the **FFT** operation.

/Z Will not rotate *srcWave* when computing the IDFT of a complex wave whose length is an integral power of 2.

This length indicates that the Inverse DFT result will also be a complex wave. When the result is complex, *and* the x scaling of *srcWave* is such that the first point is *not* x=0, it normally rotates *srcWave* by -N/2 points before performing the IFFT. This inverts the process of performing an FFT on a complex wave. However when /Z is specified, it does not perform this rotation.

Details

The data type of *srcWave* must be complex and must not be an integer type. You should be aware that an IFFT on a number of points that is prime can be slow.

By default, IFFT assumes you are performing an inverse transform on data that was originally real and therefore it produces a real result. However, for historical and compatibility reasons, IFFT detects the special conditions of a one-dimensional wave containing an integral power of 2 data points and automatically creates a complex result.

When the result is complex, the number of points (N) in the resulting wave will be of the same length. Otherwise the resulting wave will be real and of length (N-1)*2.

In either the complex or real case the X units of the output wave are changed to "s". The X scaling also is changed appropriately, cancelling out the adjustments made by the **FFT** operation. When the data is multidimensional, the same considerations apply to the additional dimensions. The scaling description and IDFT equation below pretend that the IFFT is not performed in-place. After computing the IFFT values, the X scaling of *waveOut* is changed as if Igor had executed these commands:

```
Variable points                    // time-domain points, N_timeDomain
if( waveIn was complex wave )
   points= numpnts(waveIn)
```

```
else                                    // waveIn was real wave
   points= (numpnts(waveIn) - 1) * 2
endif
Variable deltaT= 1 / (points*deltaX(waveIn))      // 1/(N_timeDomain dx)
SetScale/P waveOut 0,deltaT,"s"
```

The IDFT equation is:

$$waveOut[n] = \frac{1}{N} \cdot \sum_{k=0}^{N-1} waveIn[k] \cdot e^{-2\pi \cdot i \cdot k \cdot n/N}, \ where \ i = \sqrt{-1} \ .$$

The **FFT**, **DSPPeriodogram**, and **MatrixOp** operations.

IgorInfo

IgorInfo(*selector*)

The IgorInfo function returns information about the Igor application and the environment in which it is running.

Details

selector is a number from 0 to 5.

Always pass 0, 1, 2, 3, 4 or 5 as the input parameter. In future versions of Igor Pro, this parameter may request other kinds of information.

If *selector* is 0, IgorInfo returns a collection of assorted information. The result string contains five kinds of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are IGORVERS, IGORKIND, FREEMEM, NSCREENS, and SCREEN*n* where *n* varies from 1 to the number of screens (monitors) currently attached to the computer and used for the desktop.

Keyword	Information Following Keyword For IgorInfo(0)
FREEMEM	The amount of free memory available to Igor. When running under virtual memory, such as on Windows, this is the amount of free virtual memory.
IGORKIND	The type of Igor application; "pro" means the full (nondemo) version of Igor Pro. "pro demo" is the demo version of Igor Pro. Currently there are no other values for this keyword.
IGORVERS	The version number of the Igor application. Also see IGORFILEVERSION returned by IgorInfo(3).
NSCREENS	Number of screens (monitors) currently attached to the computer and used for the desktop. In Igor Pro 4 this was erroneously " NSCREENS" (with a leading space).
SCREEN1	Description of the characteristics of screen 1. On Macintosh, the screen number corresponds to the number in the Monitors Control Panel; use the Identify button there to show the monitor (screen) numbers. SCREEN1 is not necessarily the monitor with the menu bar. On Windows, SCREEN1 is the main monitor (whose top left corner screen coordinate is 0, 0). Format of the SCREEN description is: SCREEN*n*:DEPTH=*bitsPerPixel*,RECT=*left*,*top*,*right*,*bottom*; *left*, *top*, *right*, and *bottom* are all in pixels.
SCREEN*n*	Description of the characteristics of the last screen. See NSCREENS, above.

If *selector* is 1, IgorInfo returns the name of the current Igor experiment.

If *selector* is 2, IgorInfo returns the name of the current platform: "Macintosh" or "Windows".

If *selector* is 3, IgorInfo returns a collection of more detailed information about the operating system, localization information, and the actual file version of the Igor executable. The keywords are OS, OSVERSION, LOCALE, and IGORFILEVERSION.

Keyword	Information Following Keyword For IgorInfo(3)
IGORFILEVERSION	The actual version number of the Igor application file.
	On the Macintosh, the version number is a floating point number with a possible suffix. Igor Pro 5.00, for example, returns "5.00". Igor Pro 5.02A returns "5.02A".
	As of Igor Pro 5.02, the Windows version format is a period-separated list of four numbers. Igor Pro 5.02 returns "5.0.2.0". A revision to Igor Pro 5.02 would be indicated in the last digit, such as "5.0.2.12".
	(For versions older than 5.02, the Windows version format is a floating point number similar to the Macintosh. For example, Igor 4.09A returns "4.091". We abandoned this representation because it limits each of the digits to 0-9.)
LOCALE	Country for which this version of Igor Pro is localized. "US" for most versions, "Japan" for the Japanese versions.
OS	On Mac OS X, this will be "Macintosh OS X".
	On Windows, this might be "Windows XP (Build 1234)". The actual build number and format of the text will vary with the operating system.
OSVERSION	Operating system number.
	On Macintosh, this might be "9.1.0", "10.1.2" etc.
	On Windows, this might be "5.1.2600".

If *selector* is 4, IgorInfo returns the name of the current processor architecture: "PowerPC" or "Intel".

If *selector* is 5, IgorInfo returns (as a string) the serial number of the program if it is registered or "_none_" if it isn't registered. Use **str2num** to store the result in a numeric variable. str2num will return NaN if the program isn't registered.

Examples

```
Print NumberByKey("NSCREENS", IgorInfo(0))     // number of active displays

Function RunningWindows()                      // returns 0 if Macintosh, 1 if Windows
   String platform= UpperStr(igorinfo(2))
   Variable pos= strsearch(platform,"WINDOWS",0)
   return pos >= 0
End
```

IgorVersion

#pragma IgorVersion = *versNum*

When a procedure file contains the directive, `#pragma IgorVersion=`*versNum*, an error will be generated if *versNum* is greater than the current Igor Pro version number. It prevents procedures that use new features added in later versions from running under older versions of Igor in which these features are missing. However, this version check is limited because it does not work with versions of Igor older than 4.0.

See Also

The **The IgorVersion Pragma** on page IV-42 and **#pragma**.

IgorVersion

The IgorVersion function returns version number of the Igor application as a floating point number. Igor 6.01 returns 6.01, as does Igor 6.01A.

Details

The IgorVersion function was introduced in Igor 6.1.

The returned value is identical to that returned by more cumbersome:

```
NumberByKey("IGORVERS", IgorInfo(0))
```

This older code is compatible with older versions of Igor.

Because floating point numbers are not precise, exact comparisons to floating point values often behave in unexpected ways. For example:

```
Variable result= 6 + 0.1
if( result == 6.1 )
    Print "result == 6.1"                // this is not printed!
else
    Print "difference = ", result - 6.1  // prints "difference =   -8.88178e-16"
endif
```

However, IgorVersion compensates for this so that the following will work as expected:

```
if (IgorVersion() == 6.1)
    Print "result == 6.1"// this is printed to the history area
endif
```

You can use IgorVersion in conditionally compile code expressions, which can be used to omit calls to new Igor features or to provide backwards compatibility code.

```
#if (IgorVersion() >= 6.1)
    [Code that compiles only on Igor 6.1 or later]
#else
    [Code that compiles only on earlier versions of Igor]
#endif
```

However, this will fail with older versions which precede the IgorVersion function. To work with versions older than 6.1 you must use this instead:

```
#if NumberByKey("IGORVERS", IgorInfo(0)) >= 6.1
    [Code that compiles only on Igor 6.1 or later]
#else
    [Code that compiles only on earlier versions of Igor]
#endif
```

If at all possible, it is better to require your users to use a later version of Igor rather than writing conditional code. Attempting this kind of backward-compatibility multiplies your testing requirements and the chances for bugs.

See Also

IgorInfo, **Conditional Compilation** on page IV-86, **The IgorVersion Pragma** on page IV-42

ilim

ilim

The ilim function returns the ending loop count for the inner most iterate loop Not to be used in a function. iterate loops are archaic and should not be used.

imag

imag(*z*)

The imag function returns the imaginary component of the complex number *z* as a real (not complex) number.

See Also

The **cmplx**, **conj**, **p2rect**, **r2polar**, and **real** functions.

ImageAnalyzeParticles

ImageAnalyzeParticles [***flags***] ***keyword imageMatrix***

The ImageAnalyzeParticles operation performs one of two particle analysis operations on a 2D or 3D source wave *imageMatrix*. The source image wave must be binary, i.e., an unsigned char format where the particles are designated by 0 and the background by 255 (the operation will produce erroneous results if your data uses the opposite designation). Note that all nonzero values in the source image will be considered part of the background. Grayscale images must be thresholded before invoking this operation (you may need to use the /I flag with the **ImageThreshold** operation).

Note: ImageAnalyzeParticles does not take into account wave scaling. All image metrics are in pixels and all pixels are assumed to be square.

Parameters

keyword is one of the following names:

mark — Creates a masking image for a single particle, which is specified by an internal (seed) pixel using the /L flag. The masking image is stored in the wave M_ParticleMarker, which is an unsigned char wave. All points in M_ParticleMarker are set to 64 (image operations on binary waves use the value 64 to designate the equivalent of NaN) except points in the particle which are set to the 0. This wave is designed to be used as an overlay on the original image (using the explicit=1 mode of ModifyImage). This keyword is superseded by the **ImageSeedFill** operation.

stats — Measures the particles in the image. Results of the measurements are reported for all particles whose area exceeds the *minArea* specified by the /A flag. The results of the measurements are:

V_NumParticles	Number of particles that exceed the *minArea* limit.
W_ImageObjArea	Area (in pixels) for each particle.
W_ImageObjPerimeter	Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.
W_circularity	Ratio of the square of the perimeter to (4*π*objectArea). This value approaches 1 for a perfect circle.
W_rectangularity	Ratio of the area of the particle to the area of the inscribing (nonrotated) rectangle. This ratio is π/4 for a perfectly circular object and unity for a nonrotated rectangle.
W_SpotX and W_SpotY	Contain a single x, y point from each object. There is one entry per particle and the entries follow the same order as all other waves created by this operation. Each (x,y) point from these waves can used to define the position of a tag or annotation for a particle. Points can also be used as seed pixels for the associated *mark* method or for the ImageSeedFill operation.
W_xmin, W_xmax, W_ymin, W_ymax	Contain a single point for each particle defining an inscribing rectangular box with axes along the X and Y directions.

One of the following waves can be created depending on the /M specification. The waves are designed to be used as an overlay on the original image (using the explicit=1 mode of **ModifyImage**). **Note**: the additional time required to create these waves is negligible compared with the time it takes to generate the stats data.

M_ParticlePerimeter	Masking image of particle boundaries. It is an unsigned char wave that contains 0 values for the object boundaries and 64 (i.e., NaN) for all other points.
M_ParticleArea	Masking image of the area occupied by the particles. It is an unsigned char wave containing 0 values for the object boundaries and 64(=NaN) for all other points. It is also different from the input image in that particles smaller than the minimum size, specified by /A, are absent.
M_Particle	Image of both the area and the boundary of the particles. It is an unsigned char wave that contains the value 16 for object area, the value 18 for the object boundaries and the value 64(=NaN) for all other points.
M_rawMoments	Contains five columns. The first column is the raw sum of the x values for each particle, and the second column contains the sum of the y values. To obtain the average or "center" of a particle divide these values by the corresponding area. The third column contains the sum of x^2, the fourth column the sum of y^2, and the fifth column the sum of x*y. The entries of this wave are used in calculating a fit to an ellipse (using the /E flag).

When *imageMatrix* is a 3D wave, the different results are packed into a single 2D wave M_3DParticleInfo, which consists of one row and 11 columns for each particle. Columns are arranged in the following order: minRow, maxRow, minCol, maxCol, minLayer, maxLayer, xSeed, ySeed, zSeed, volume, and area. Use `Edit M_3DParticleInfo.ld` to display the results in a table with dimension labels describing the different columns.

Flags

/A=*minArea* Specifies a minimum area as a threshold that must be exceeded for a particle to be counted (e.g., use *minArea*=0 to find single pixel particles). The minimum area is measured in pixels; its default value is *minArea*=5.

Has no effect when used with the *mark* method.

/CIRC={*minCircularity*,*maxCircularity*}

Use this flag to filter the output so that only particles in the range of the specified circularity are counted.

/D=*dataWave* Specify a wave from which the minimum, maximum, and total particle intensity are sampled when used with the stats keyword. dataWave must be of the same dimensions as the input binary image imageMatrix. It can be of any real numeric type. Results are returned in the waves W_IntMax, W_IntMin, and W_IntAvg.

/E Calculates an ellipse that best fits each particle. The equivalent ellipse is calculated by first finding the moments of the particle (i.e., average x-value, average y-value, average x^2, average y^2, and average x*y), and then requiring that the area of the ellipse be equal to that of the particle. The resulting ellipses are saved in the wave M_Moments. When *imageMatrix* is a 2D wave, the results returned in M_Moments are the columns: the X-center of the ellipse, the Y-center of the ellipse, the major axis, the minor axis, and the angle (radians) that the major axis makes with the X-direction. When *imageMatrix* is a 3D wave, the results in M_Moments include the sum of the X, Y, and Z components as well as all second order permutations of their products. They are arranged in the order: sumX, sumY, sumZ, sumXX, sumYY, sumZZ, sumXY, sumXZ, and sumYZ.

/EBPC Use this flag to exclude from counting any particle that has one or more pixels on any boundary of the image.

/F Fills 2D particles having internal holes and adjusts their area measure for the removal of holes. Internal boundaries around the holes are also eliminated. When the boundary of the particle consists of thin elements that cannot be traversed as a single closed path which passes each boundary pixel only once, the particle will not be filled. Note that filling particles may increase execution time considerably and on some images it may require large amount of memory. It is likely that a more efficient approach would be to preprocess the binary image and remove holes using morphology operations. This flag is not supported when *imageMatrix* is a 3D wave.

/L= (*row*,*col*) Specifies a 2D particle location in connection with the mark method. (*row*, *col*) is a seed value corresponding to any pixel inside the particle. If the seed belongs to the particle boundary, the particle will not be filled. This flag is not supported when *imageMatrix* is a 3D wave.

/M=*markerVal* Use this flag with the stats mode for 2D images. See stats keyword for a full description of the following waves:

markerVal=0: No marker waves.

markerVal=1: M_ParticlePerimeter.

markerVal=2: M_ParticleArea.

markerVal=3: M_Particle.

This flag does not apply to 3D waves.

/MAXA=*maxArea* Specifies an upper limit of the area of an acceptable particle when used with the stats keyword. The area is measured in pixels and the default value of *maxArea* is the number of pixels in the image. In 3D the maximum value applies to the number of voxels.

/NSW Creates the marker wave (see /M flag) but not the particle statistics waves when used with the stats keyword. This should reduce execution time in images containing many particles.

/P=*plane* Specifies the plane when operating on a single layer of a 3D wave.

/Q Quiet flag, does not report the number of particles to the history window.

/R=*roiWave* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u) that has the same number of rows and columns as *imageMatrix*. The ROI itself is defined by the entries or pixels in the *roiWave* with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When *imageMatrix* is a 3D wave, *roiWave* can be either a 2D wave (matching the number of rows and columns in *imageMatrix*) or it can be a 3D wave that must have the same number of rows, columns

and layers as *imageMatrix*. When using a 2D *roiWave* with a 3D *imageMatrix* the ROI is understood to be defined by *roiWave* for each layer in the 3D wave.

See **ImageGenerateROIMask** for more information on creating 2D ROI waves.

/U — Saves the wave M_ParticleMarker as an 8-bit unsigned instead of the default 16-bit when used with the mark keyword.

/W — Creates boundary waves W_BoundaryX, W_BoundaryY, and W_BoundaryIndex for a 2D *imageMatrix* wave. W_BoundaryX and W_BoundaryY contain the pixels along the particle boundaries. The boundary of each particle ends with a NaN entry in both waves. Each entry in W_BoundaryIndex is the index to the start of a new particle in W_BoundaryX and W_BoundaryY, so that you can quickly locate the boundary of each particle.

When there are holes in particles, the entries in W_BoundaryX and W_BoundaryY start with the external boundary followed by all the internal boundaries for that particle. There are no index entries for internal boundaries.

This flag is not supported when *imageMatrix* is a 3D wave.

Details

Particle analysis is accomplished by first converting the data from its original format into a binary representation where the particle is designated by zero and the background by any nonzero value. The algorithm searches for the first pixel or voxel that belongs to a particle and then grows the particle from that seed while keeping count of the area, perimeter and count of pixels or voxels in the particle. If you use additional flags, the algorithm must compute additional quantities for each pixel or voxel belonging to the particle.

If your goal is to mask only the particle, a more efficient approach is to use the **ImageSeedFill** operation, which similarly follows the particle but does not spend processing time on computing unrelated particle properties. ImageSeedFill also has the additional advantage of not requiring that the input wave be binary, which will save time on performing the initial threshold and, in fact, may produce much better results with the adaptive/fuzzy features that are not available in ImageAnalyzeParticles.

Examples

Convert a grayscale image (blobs) into a proper binary input:

```
ImageThreshold/M=4/Q/I blobs
```

Get the statistics on the thresholded image of blobs and create an image mask output wave for the perimeter of the particles:

```
ImageAnalyzeParticles/M=1 stats M_ImageThresh
```

Display an image of the blobs with a red overlay of the perimeter image:

```
NewImage/F blobs; AppendImage M_ParticlePerimeter
ModifyImage M_ParticlePerimeter explicit=1, eval={0,65000,0,0}
```

See Also

The **ImageThreshold**, **ImageGenerateROIMask**, **ImageSeedFill**, and **ModifyImage** operations. For more usage details see **Particle Analysis** on page III-319.

ImageBlend

ImageBlend [**/A=*alpha* /W=*alphaWave***] ***srcWaveA, srcWaveB*** [**, *destWave***]

The ImageBlend operation takes two RGB images (3D waves) in *srcWaveA* and *srcWaveB* and computes the alpha blending so that

destWave = *srcWaveA* * (1 - *alpha*) + *srcWaveB* * *alpha*

for each color component. If *destWave* is not specified or does not already exist, the result is saved in the current data folder in the wave M_alphaBlend.

The source and destination waves must be of the same data types and the same dimensions. The *alphaWave*, if used, must be a single precision (SP) float wave and it must have the same number of rows and columns as the source waves.

Flags

/A=*alpha* — Specifies a single alpha value for the whole image

/W=*alphaWave* — Single precision wave that specifies an alpha value for each pixel.

ImageBoundaryToMask

ImageBoundaryToMask width=*w*, height=*h*, xwave=*xwavename*, ywave=*ywavename* [, scalingWave=*scalingWaveName*, [seedX=*xVal*, seedY=*yVal*]]

The ImageBoundaryToMask operation scan-converts a pair of XY waves into an ROI mask wave.

Parameters

height = *h* Specifies the mask height in pixels.

scalingWave = *scalingWaveName*
2D or 3D wave that provides scaling for the mask. If specified, the scaling of the first two dimensions of scalingWave are copied to M_ROIMask, and both the X and Y waves are assumed to describe pixels in the scaled domain.

seedX = *xVal* Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedY.

seedY = *yVal* Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedX.

width = *w* Specifies the mask width in pixels.

xwave = *xwavename* Name of X wave for mask region.

ywave = *ywavename* Name of Y wave for mask region.

Details

ImageBoundaryToMask generates an unsigned char 2D wave named M_ROIMask, of dimensions specified by width and height. The wave consists of a background pixels that are set to 0 and pixels representing the mask that are set to 1.

The x and y waves can be of any type. However, if the waves describe disjoint regions there must be at least one NaN entry in each wave corresponding to the discontinuity, which requires that you use either single or double precision waves. The values stored in the waves must correspond to zero-based integer pixel values.

If the x and y waves include a vertex that lies outside the mask rectangle, the offending vertex is moved to the boundary before the associated line segment is scan converted.

If you want to obtain a true ROI mask in which closed regions are filled, you can specify the seedX and seedY keywords. The ROI mask is set with zero outside the boundary of the domain and 1 everywhere inside the domain.

Examples

```
Make/O/N=(100,200) src=gnoise(5)            // create a test image
SetScale/P x 500,1,"", src;DelayUpdate      // give it some funny scaling
SetScale/P y 600,1,"", src
Display; AppendImage src
Make/O/N=201 xxx,yyy                 // create boundary waves
xxx=550+25*sin(p*pi/100)             // representing a close ellipse
yyy=700+35*cos(p*pi/100)
AppendToGraph yyy vs xxx
```

Now create a mask from the ellipse and scale it so that it will be appropriate for src:

```
ImageBoundaryToMask ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src
```

To generate an ROI masked filled with 1 in a region defined by a seed value and the boundary curves:

```
ImageBoundaryToMask
ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src,seedx=550,seedy=700
```

ImageEdgeDetection

ImageEdgeDetection [*flags*] *Method imageMatrix*

The ImageEdgeDetection operation performs one of several standard image edge detection operations on the source wave *imageMatrix*. Unless the /O flag is specified, the resulting image is saved in the wave M_ImageEdges. The edge detection methods produce binary images on output (the background is set to 0 and the edges to 255). This is due, in most cases to a thresholding performed in the final stage. Except for

the case of marr and shen detectors, you can use the /M flag to specify a method for automatic thresholding (see **ImageThreshold** /M flag).

Parameters

Method selects type of edge detection. *Method* is one of the following names:

canny	Canny edge detector uses smoothing before edge detection and thresholding. You can optionally specify the threshold using the /T flag and the smoothing factor using /S.
frei	Calculates the Frei-Chen edge operator (see Pratt p. 503) using only the row and column filters.
kirsch	Kirsch edge detector (see Pratt p. 509). Performs convolution with 8 masks calculating gradients.
marr	Marr-Hildreth edge detector. Performs two convolutions with Laplacian of Gaussian and then detects zero crossings. Use the /S flag to define the width of the convolution kernel.
prewitt	Calculates the Prewitt compass gradient filters. Returns the result for the largest filter response.
roberts	Calculates the square root of the magnitude squared of the convolution with the Robert's row and column edge detectors.
shen	Shen-Castan optimized edge detector. Supposed to be effective in the presence of noise. The flags that modify this operation are: /F for the threshold ratio (0.9 by default), /S for smoothness factor (0.9 by default), /W for window width (default is 10), /H for thinning factor which by default is 1.
sobel	Sobel edge detector using convolutions with row and column edge gradient masks (see Pratt p. 501).

Flags

/F=*fraction*	Determines the threshold value for the shen algorithm by starting from the histogram of the image and choosing a threshold such that *fraction* specifies the portion of the image pixels whose values are below the threshold. Valid values are in the interval (0 < *fraction* < 1).
/H=*thinning*	Thins edges when used with shen edge detector. By default the thinning value is 1. Higher values produce thinner edges.
/I	Inverts the output, i.e., sets the edges to 255 and the background to 0.
/M=*threshMethod*	See the **ImageThreshold** automatic methods for obtaining a threshold value. Methods 1, 2, 4 and 5 are supported in this operation. If you use *threshMethod* = -1, threshold is not applied. If you want to apply your own thresholding algorithm, use /M=6 to bypass the thresholding completely. The wave M_RawCanny contains the result regardless of any other flags you may have used.
/N	Sets the background level to 64 (i.e., NaN)
/O	Overwrites the source image with the output image.
/R=*roiSpec*	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by entries/pixels whose values are 0. Pixels outside the ROI can be any nonzero value. The ROI does not have to be contiguous and can be any arbitrary shape. See **ImageGenerateROIMask** for more information on creating ROI waves. In general, the *roiSpec* has the form {*roiWaveName*, *roiFlag*}, where *roiFlag* can take the following values: *roiFlag*=0: Set pixels outside the ROI to 0. *roiFlag*=1: Set pixels outside the ROI as in original image. *roiFlag*=2: Set pixels outside the ROI to NaN (=64). By default *roiFlag* is set to 1 and it is then possible to use the /R flag using the abbreviated form /R=*roiWave*.
/S= *smoothVal*	Specifies the standard deviation or the width of the smoothing filter. By default the operation uses 1. Larger values require longer computation time. In the shen operation the default value is 0.9 and the valid range is (0 < *smoothVal*< 1).
/T=*thresh*	Sets a manual threshold for any method above that uses a single threshold. This is faster than using /M.
/W=*width*	Specifies window width when used in the shen operation. By default width is set to 10 and it is clipped to 49.

References

Pratt, William K., *Digital Image Processing*, John Wiley, New York, 1991.

ImageFileInfo

ImageFileInfo [**/P=*pathName***] ***fileNameStr***

The ImageFileInfo operation supplies information about an image file without having to open the file and load the data into Igor.

ImageFileInfo works with the following file types: PICT, TIFF, GIF, JPEG, PNG, Targa, QuickTime, and BMP.

ImageFileInfo requires QuickTime. The operation will fail (V_flag=0) if you request information for a file format that is not supported by QuickTime.

Parameters

fileNameStr specifies the image file for which information is needed.

The file of interest is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-398 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter.

Flags

/P=*pathName* Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.

Variables

ImageFileInfo returns information in the following variables:

S_path	File system path to the selected file.
V_BPP	Number of bits per pixel. A value of 40 means 8-bit grayscale; all other values are bits per pixel.
V_flag	1 if operation was successful, 0 otherwise.
V_frameCount	Number of movie frames.
V_numCols	Height of the image.
V_numImages	Number of images in the file. Only supports TIFF files that contain multiple images.
V_numRows	Width of the image.
V_quality	Image compression quality in hexadecimal: codecLosslessQuality = 0x00000400 codecMaxQuality = 0x000003FF codecMinQuality = 0x00000000 codecLowQuality = 0x00000100 codecNormalQuality = 0x00000200 codecHighQuality = 0x00000300

ImageFilter

ImageFilter [***flags***] ***Method dataMatrix***

The ImageFilter operation is identical to **MatrixFilter**, accepting the same parameters and flags, with the exception of the additional features described below.

Parameters

Method selects the filter type. *Method* is one of the following names:

avg3d *nxnxn* average filter for 3D waves.

gauss3d	*n*x*n*x*n* gaussian filter for 3D waves.
hybridmedian	Implements ranking pixel values between two groups of pixels in a 5x5 neighborhood. The first group includes horizontal and vertical lines through the center, the second group includes diagonal lines through the center, and both groups include the center pixel itself. The resulting median value is the ranked median of both groups and the center pixel.
max3d	*n*x*n*x*n* maximum rank filter for 3D waves.
median3d	*n*x*n*x*n* median filter for 3D waves where *n* must be of the form 3^r (integer *r*), e.g., 3x3x3, 9x9x9 etc. The filter does not change the value of the voxel it is centered on if any of the filter voxels lies outside the domain of the data.
min3d	*n*x*n*x*n* minimum rank filter for 3D waves.
point3d	*n*x*n*x*n* point finding filter using normalized `(`n^3`-1)*`*center-outer* for 3D waves.

Flags

/N=*n*	Specifies the filter size. By default *n* =3. In most situations it will be useful to set *n* to an odd number in order to preserve the symmetry in the filters.
/O	Overwrites the source image with the output image. Used only with the hybridmedian filter, which does not automatically overwrite the source wave.

Details

You can operate on 3D waves using the 3D filters listed above. These filters are extensions of the 2D filters available under MatrixFilter. The avg3d, gauss3d, and point3d filters are implemented by a 3D convolution that uses an averaging compensation at the edges.

This operation does not support complex waves.

See Also

MatrixFilter for descriptions of the other available parameters and flags.

MatrixConvolve for information about convolving your own 3D kernels.

References

Russ, J., *Image Processing Handbook*, CRC Press, 1998.

ImageFocus

ImageFocus [***flags***] ***stackWave***

The ImageFocus operation creates in focus image(s) from a stack of images that contain in and out of focus regions. It computes the variance in a small neighborhood around each pixel and then takes the pixel value from the plane in which the highest variance is found.

Flags

/ED=*edepth*	Sets the effective depth in planes. For example, an effective depth of one means that it computes the best focus for each plane using a stack of three planes, which includes the current plane and any one adjacent plane above and below it. Does not affect the default method (/METH=0).
/METH=*method*	Specifies the calculation method. *method*=0: Computes a single plane output for the stack (default). *method*=1: Computes the best image for each plane using /ED.
/Q	Quiet mode; no output to history window.
/Z	No error reporting.

See Also

Chapter III-11, **Image Processing** contains links to and descriptions of other image operations.

ImageGenerateROIMask

ImageGenerateROIMask [**/W=*winName*/E=*e*/I=*i***] ***imageInstance***

The ImageGenerateROIMask operation creates a Region Of Interest (ROI) mask for use with other ImageXXX commands. It assumes the top (or /W specified) graph contains an image and that the user has drawn shapes using Igor's drawing tools in a specific manner.

ImageGenerateROIMask creates an unsigned byte mask matrix with the same x and y dimensions and scaling as the specified image. The mask is initially filled with zeros. Then the drawing layer, progFront, in the graph is scanned for suitable fillable draw objects. The area inside each shape is filled with ones unless the fill mode for the shape is set to erase in which case the area is filled with zeros.

Flags

/E=*e* Changes value used for the exterior from the default zero values to *e*.

/I=*i* Changes value used for the interior from the default one values to *i*.

/W=*winName* Looks for the named graph window or subwindow containing appropriate image masks drawn by the user. If /W is omitted, ImageGenerateROIMask uses the top graph window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

Suitable objects are those that can be filled (rectangles, ovals, etc.) and which are plotted in axis coordinate mode specified using the same axes by which the specified image instance is displayed. Objects plotted in plot relative mode are also used, However, this is not recommended because it will give correct results only if the image exactly fills the plot rectangle. If you use axis coordinate mode then you can zoom in or out as desired and the resulting mask will still be correct.

Note that the shapes can have their fill mode set to none. This still results in a fill of ones. This is to allow the drawn ROI to be visible on the graph without obscuring the image. However cutouts (fills with erase mode) will obscure the image.

Note also that nonfill drawing objects are ignored. You can use this fact to create callouts and other annotations.

In a future version of Igor, we may create a new drawing layer in graphs dedicated to ROIs.

The mask generated is named M_ROIMask and is generated in the current data folder.

Variable V_flag is set to 1 if the top graph contained draw objects in the correct layer and 0 if not. If 0 then the M_ROIMask wave was not generated.

Examples

```
Make/O/N=(200,400) jack=x*y; NewImage jack; ShowTools
SetDrawLayer ProgFront
SetDrawEnv linefgc=(65535,65535,0),fillpat=0,xcoord=top,ycoord=left,save
DrawRect 63.5,79.5,140.5,191.5
DrawRRect 61.5,206.5,141.5,280.5
SetDrawEnv fillpat= -1
DrawOval 80.5,169.5,126.5,226.5
ImageGenerateROIMask jack
NewImage M_ROIMask
AutoPositionWindow/E
```

See Also

For another example see **Generating ROI Masks** on page III-322.

ImageHistModification

ImageHistModification [***flags***] ***imageMatrix***

The ImageHistModification operation performs a modification of the image histogram and saves the results in the wave M_ImageHistEq. If /W is not specified, the operation is a simple histogram equalization of *imageMatrix*. If /W is specified, the operation attempts to produce an image with a histogram close to *waveName*. If /A is specified, the operation performs an adaptive histogram equalization. *imageMatrix* is a wave of any noncomplex numeric type. Adaptive histogram equalization applies only to 2D waves and the other parts apply to both 2D and 3D waves.

Flags

/A Performs an adaptive histogram equalization by subdividing the image into a minimum of 4 rectangular domains and using interpolation to account for the boundaries between adjacent domains. When the /C flag is specified with contrast factor greater than 1, this operation amounts to contrast-limited adaptive histogram equalization. By default the operation divides the image into 8 horizontal and 8 vertical regions. See /H and /V.

/B=*bins* Specifies the number of *bins* used with the /A flag. If not specified, this value defaults to 128.

/C=*cFactor* Specifies a contrast factor (or clipping value) above which pixels are equally distributed over the whole range. *cFactor* must be greater than 1, in the limit as *cFactor* approaches 1 the operation is a regular adaptive histogram equalization. **Note**: this flag is used only with the /A flag.

/H=*hRegions* Specifies the number of horizontal subdivisions to be used with the /A feature. Note, the number of image pixels in the horizontal direction must be an integer multiple of *hRegions*.

/I Extends the standard histogram equalization by using 2^{16} bins instead of 2^8 when calculating histogram equalization. This feature does not apply to the adaptive histogram equalization (/A flag).

/O Overwrites the source image. If this flag is not specified, the resulting image is saved in the wave M_ImageHistEq.

/R=*roiSpec* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as *imageMatrix*. The ROI itself is defined by the entries whose values are 0. Regions outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape.

In general, the *roiSpec* has the form {*roiWaveName*, *roiFlag*}, where *roiFlag* can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.

roiFlag=1: Set pixels outside the ROI as in original image (default).

roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default *roiFlag* is set to 1 and it is then possible to use the /R flag with the abbreviated form /R=*roiWave*. When *imageMatrix* is a 3D wave, *roiWave* can be either a 2D wave (matching the number of rows and columns in *imageMatrix*) or it can be a 3D wave which must have the same number of rows, columns, and layers as *imageMatrix*. When using a 2D *roiWave* with a 3D *imageMatrix*, the ROI is understood to be defined by *roiWave* for each layer in the 3D wave.

See **ImageGenerateROIMask** for more information on creating ROI waves.

/V=*vRegions* Specifies the number of vertical subdivisions to be used with the /A flag. The number of image pixels in the horizontal direction must be an integer multiple of *vRegions*. If the image dimensions are not divisible by the number of regions that you want, you can pad the image using **ImageTransform padImage**.

/W=*waveName* Specifies a 256-point wave that provides the desired histogram. The operation will attempt to produce an image having approximately the desired histogram values. This flag does not apply to the adaptive histogram equalization (/A flag)

See Also

The **ImageGenerateROIMask** and **ImageTransform** operations for creating ROIs. For examples see **Histograms** on page III-316 and **Adaptive Histogram Equalization** on page III-299.

ImageHistogram

ImageHistogram [***flags***] ***imageMatrix***

The ImageHistogram operation calculates the histogram of *imageMatrix*. The results are saved in the wave W_ImageHist. If *imageMatrix* is an RGB image stored as a 3D wave, the resulting histograms for each color plane are saved in W_ImageHistR, W_ImageHistG, W_ImageHistB.

imageMatrix must be a real-valued numeric wave.

Flags

/I Calculates a histogram with 65536 bins evenly distributed between the minimum and maximum data values. The operation first finds the extrema and then calculates the bins and the resulting histogram. Data can be a 2D wave of any type including float or double.

/P=*plane* Restricts the calculation of the histogram to a specific plane when *imageMatrix* is a non RGB 3D wave.

/R=*roiWave* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u) that has the same number of rows and columns as *imageMatrix*. The ROI itself is defined by the entries o pixels in the *roiWave* with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When *imageMatrix* is a 3D wave, *roiWave* can be either a 2D wave (matching the number of rows and columns in *imageMatrix*) or it can be a 3D wave that must have the same number of rows, columns and layers as *imageMatrix*. When using a 2D *roiWave* with a 3D *imageMatrix* the ROI is understood to be defined by *roiWave* for each layer in the 3D wave.

See **ImageGenerateROIMask** for more information on creating 2D ROI waves.

/S Computes the histogram for a whole 3D wave possibly subject to 2D or 3D ROI masking. The /S and /P flags are mutually exclusive.

Details

The ImageHistogram operation works on images, but it handles both 2D and 3D waves of any data type. Unless you use one of the special features of this operation (e.g., ROI or /P or /I) you could alternatively use the **Histogram** operation, which computes the histogram for the full wave and includes additional options for controlling the number of bins.

If the data type of *imageMatrix* is single byte, the histogram will have 256 bins from 0 to 255. Otherwise, the 256 bins will be distributed between the minimum and maximum values encountered in the data. Use the /I flag to increase the number of bins to 65536, which may be useful for unsigned short (/W/U) data.

See Also

The **ImageHistModification** and **ImageGenerateROIMask** operations. For examples see **Histograms** on page III-316.

ImageInfo

ImageInfo(*graphNameStr, imageWaveNameStr, instanceNumber*)

The ImageInfo function returns a string containing a semicolon-separated list of information about the specified image in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

imageWaveNameStr contains either the name of a wave displayed as an image in the named graph, or an image instance name (wave name with "#n" appended to distinguish the nth image of the wave in the graph). You might get an image instance name from the **ImageNameList** function.

If *imageWaveNameStr* contains a wave name, *instanceNumber* identifies which instance you want information about. *instanceNumber* is usually 0 because there is normally only one instance of a wave displayed as an image in a graph. Set *instanceNumber* to 1 for information about the second image of the wave, etc. If *imageWaveNameStr* is "", then information is returned on the *instanceNumber*th image in the graph.

If *imageWaveNameStr* contains an instance name, and *instanceNumber* is zero, the instance is taken from *imageWaveNameStr*. If *instanceNumber* is greater than zero, the wave name is extracted from *imageWaveNameStr*, and information is returned concerning the *instanceNumber*th instance of the wave.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon for ease of use with **StringByKey**. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
COLORMODE	A number indicating how the image colors are derived: 1: Color table (see **Color Tables** on page II-349). 2: Scaled color index wave (see **Indexed Color Details** on page II-356). 3: Point-scaled color index (See **Example: Point-Scaled Color Index Wave** on page II-357). 4: Direct color (see **Direct Color Details** on page II-358). 5: Explicit Mode (See **ModifyImage** explicit keyword).
RECREATION	Semicolon-separated list of *keyword=modifyParameters* commands for the ModifyImage command.
XAXIS	X axis name.
XWAVE	X wave name if any, else blank.
XWAVEDF	The full path to the data folder containing the X wave or blank if there is no X wave.
YAXIS	Y axis name.
YWAVE	Y wave name if any, else blank.
YWAVEDF	The full path to the data folder containing the Y wave or blank if there is no Y wave.
ZWAVE	Name of wave containing Z data used to calculate the image plot.
ZWAVEDF	The full path to the data folder containing the Z data wave.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the "`;`", prepend "`ModifyImage `", replace the "`x`" with the name of a image plot ("`data#1`" for instance) and then **Execute** the resultant string as a command.

Example 1

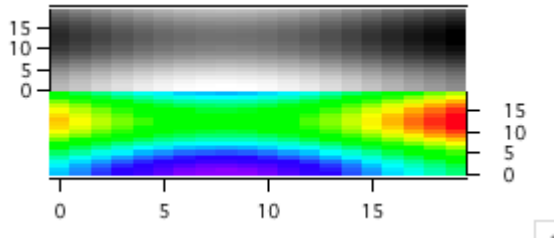
This example gets the image information for the second image plot of the wave "jack" (which has an instance number of 1) and applies its **ModifyImage** settings to the first image plot.

```
#include <Graph Utility Procs>, version>=6.1   // For WMGetRECREATIONFromInfo

// Make two image plots of the same data on different left and right axes
Make/O/N=(20,20) jack=sin(x/5)+cos(y/4)
Display;AppendImage jack                        // bottom and left axes
AppendImage/R jack                              // bottom and right axes

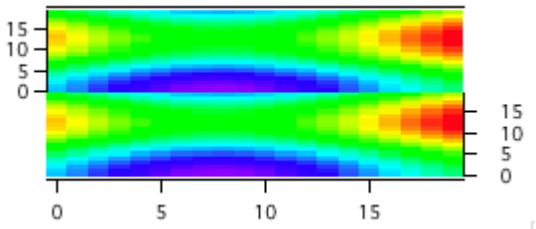
// Put image plot jack#0 above jack#1
ModifyGraph axisEnab(left)={0.5,1},axisEnab(right)={0,0.5}

// Set jack#1 to use the Rainbow color table instead of the default Grays
ModifyImage jack#1 ctab={*,*,Rainbow,0}
```



Now we peek at some of the image information for the second image plot of the wave "jack" (which has an instance number of 1) displayed in the top graph:

```
Print ImageInfo("","jack",1)[69,148]        // Just the interesting stuff
;ZWAVE:jack;ZWAVEDF:root:;COLORMODE:1;RECREATION:ctab= {*,*,Rainbow,0};plane= 0;
// Apply the color table, etc from jack#1 to jack:
String info= WMGetRECREATIONFromInfo(ImageInfo("","jack",1))
info= RemoveEnding(info)                    // Remove trailing semicolon
// Use comma instead of semicolon separators
String text = ReplaceString(";", info, ",")
Execute "ModifyImage jack " + text
```



Example 2

This example gets the full path to the wave containing the Z data from which the first image plot in the top graph was calculated.

```
String info= ImageInfo("","",0)      // 0 is index of first image plot
String pathToZ= StringByKey("ZWAVEDF",info)+StringByKey("ZWAVE",info)
Print pathToZ
   root:jack
```

How Images Are Displayed on page II-346.

Image Instance Names on page II-360.

ImageInterpolate

ImageInterpolate [*flags*] ***Method srcWave***

The ImageInterpolate operation interpolates the source *srcWave* and stores the results in the wave M_InterpolatedImage in the current data folder unless you specify a different destination wave using the /DEST flag.

Parameters

Method selects type of interpolation. *Method* is one of the following names:

Affine2D Performs an affine transformation on *srcWave* using parameters specified by the /APRM flag. The transformation applies to a general combination of rotation, scaling, and translation represented by a 3x3 matrix

$$M = \begin{bmatrix} r_{11} & r_{12} & tx \\ r_{21} & r_{22} & ty \\ 0 & 0 & w \end{bmatrix}$$

The upper 2x2 matrix is a composite of rotation and scaling, *tx* and *ty* are composite translations and *w* is usually 1. It computes the dimensions of the output wave and then uses the inverse transformation and bilinear interpolation to compute the value of each output pixel. When an output pixel does not map back into the source domain it is set to the user-specified background value. It supports 2D and 3D input waves. If *srcWave* is a 3D wave it applies on a layer by layer basis.

The output is stored in the wave M_Affine in the current data folder.

Bilinear Performs a bilinear interpolation subject to the specified flag. You can use either the /F or /S flag, but not both.

Kriging — Uses Kriging to generate an interpolated matrix from a sparse data set. Kriging calculates interpolated values for a rectangular domain specified by the /S flag. The Kriging parameters are specified via the /K flag.

Kriging is computed globally for a single user-selected variogram model. If there are significant spatial variances within the domain occupied by the data, you should consider subdividing the domain along natural boundaries and use a single variogram model in each subdivision.

If there are N data points, the algorithm first computes the NxN matrix containing the distances between the data and then inverts an associated matrix of similar size to compute the result for the selected variogram model. Because inversion of an NxN matrix can be computationally expensive, you should consider restricting the calculation to regions that are similar to the range implied by the variogram. Such an approach can also be justified in the sense that the local interpolation should not be affected by a remote datum.

Note: Kriging does not support data containing NaNs or INFs. Wave scaling has no effect.

Pixelate — Creates a lower resolution (pixelated image) of *srcWave* by averaging the pixels inside rectangles specified by /PXSZ flag. The results are saved in the wave M_PixelatedImage in the current data folder. The computed wave has the same numeric type as *srcWave* and the same number of layers. The number of rows and the number of columns of the new image are obtained by integer division of the original number by the respective size of the averaging rectangle and adding one more pixel for any remainder.

Resample — Computes a new image based on the selected interpolation function and transformation parameters. Set the interpolation function with the /FUNC flag. Use the /TRNS flag to specify transformation parameters for grayscale images, or /TRNR, /TRNG, and /TRNB for the red, green, and blue components, respectively, of RGB images. M_InterpolatedImage contains the output image in the current data folder.

There are currently two transformation functions: the first magnifies an image and the second applies a radial polynomial sampling. The radial polynomial affects pixels based on their position relative to the image center. A linear polynomial reproduces the same image. Any nonlinear terms contribute to distortion (or correction thereof).

Spline — Computes a 2D spline interpolation for 2D matrix data. The degree of the spline is specified by the /D flag.

Voronoi — Generates an interpolated matrix from a sparse data set (*srcWave* must be a triplet wave) using Voronoi polygons. It calculates interpolated values for a rectangular domain as specified by the /S flag. It first computes the Delaunay triangulation of X, Y locations in the Z=0 plane (assuming that X, Y positions occupy a convex domain in the plane). It then uses the Voronoi dual to interpolate the Z values for X and Y pairs from the grid defined by the /S flag. The computed grid may exceed the bounds of the convex domain defined by the triangulation. Interpolated values for points outside the convex domain are set to NaN or the value specified by the /E flag. Use the /I flag to iterate to finer triangulation by subdividing the original triangles into smaller domains. Each iteration increases computation time by approximately a factor of two, but improves the smoothness of the interpolation.

If you have multiple sets of data in which X,Y locations are unchanged, you can use the /STW flag to store one triangulation and then use the /PTW flag to apply the precomputed triangulation to a new interpolation. To use this option you should use the Voronoi keyword first with a triplet wave for *srcWave* and set xn = x0 and yn = y0. The operation creates the wave W_TriangulationData that you use in the next triangulation with a 1D wave as *srcWave*. For example:

```
ImageInterpolate/STW/S={0,1,0,1,1,1} Voronoi myTripletWave
ImageInterpolate/PTW=W_TriangulationData/S={0,1,0,1,1,1} Voronoi my1DZWave
```

Voronoi interpolation is similar to what can be accomplished with the **ContourZ** function except that it does not require an existing contour plot, it computes the whole output matrix in one call, and it has the option of controlling the subdivision iterations.

XYWaves — Performs bilinear interpolation on a matrix scaled using two X and Y 1D waves (specified by /W). The interpolation range is defined by /S. The data domain is defined between the centers of the first and last pixels (X in this example):

```
xmin=(xWave[0]+xWave[1])/2
xmax=(xWave[last]+xWave[last-1])/2
```

Values outside the domain of the data are set to NaN. The interpolation is contained in the M_InterpolatedImage wave, which is single precision floating point or double precision if *srcWave* is double precision.

Warp Performs image warping interpolation using a two step algorithm with three optional interpolation methods. The operation warps the image based on the relative positions of source and destination grids. The warped image has the same size as the source image. The source and destination grids are each specified by a pair of 2D X and Y waves where the rows and columns correspond to the relative location of the source grid. The smallest supported dimensions of grid waves are 2x2. All grid waves must be double-precision floating point and must have the same number of points corresponding to pixel positions within the image. Grid waves must not contain NaNs or INFs. Wave scaling is ignored.

Flags

/APRM={*r11*,*r12*,*tx*,*r21*,*r22*,*ty*,*w*,*background*}
Sets elements of the affine transformation matrix and the background value.

/D=*splineDeg* Specifies the spline degree with the Spline method. The default spline degree is 2. Supported values are 2, 3, 4, and 5.

/DEST=*destWave*

Specifies the wave to contain the output of the operation. If the specified wave already exists, it is overwritten.

Creates a wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-56 for details.

/E=*outerValue* Assigns *outerValue* to all points outside the convex domain of the Delaunay triangulation. By default *outerValue* = NaN.

/F={*fx*,*fy*} Calculates a bilinear interpolation of all the source data. Here *fx* is the sampling factor for the X-direction and *fy* is the sampling factor in the Y-direction. The output number of points in a dimension is factor*(number of data intervals) +1. The number of data intervals is one less than the number of points in that dimension.

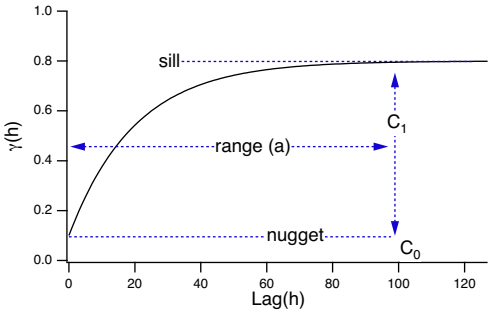
For example, if *srcWave* is a 2x2 matrix (you have a single data interval in each direction) and you use /F={2,2}, then the output wave is a 3x3 matrix (i.e., 2x2 intervals) which is a factor of 2 of the input. Sampling factors can be noninteger values.

/FUNC=*funcName* Specifies the interpolation function. *funcName* can be:

- nn Nearest neighbor interpolation uses the value of the nearest neighbor without interpolation. This is the fastest function.
- bilinear Bilinear interpolation uses the immediately surrounding pixels and computes a linear interpolation in each dimension. This is the second fastest function.
- cubic Cubic polynomial (photoshop-like) uses a 4x4 neighborhood value to compute the sampled pixel value.
- spline Spline smoothed sampled value uses a 4x4 neighborhood around the pixel.
- sinc Slowest function using a 16x16 neighborhood.

/I=*iterations* Specifies the number of times the original triangulation is subdivided with the Voronoi interpolation method. By default the Voronoi interpolation computes the original triangulation without subdivision.

/K={*model*, *nugget*, *sill*, *range*}
Specifies the variogram parameters for kriging using standard notation, models are expressed in terms of the nugget value C_0, sill value C_0+C_1, and range a.



model Selects the variogram model. Values and models are:

1: Spherical. $\gamma(h) = C_0 + C_1 \cdot (3h/2a - 0.5 \cdot h^2/a^2)$

2: Exponential. $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot h/a])$

3: Gaussian. $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot (h/a)^2])$

nugget Specifies the lowest value in the variogram.

sill Specifies the maximum (plateau) value in the variogram range the characteristic length of the different variogram models.

Wave scaling has no effect on kriging calculations.

/PTW=*tWave* Uses a previous triangulation wave with Voronoi interpolation. *tWave* will be the wave saved by the /STW flag. You can't use a triangulation wave that was computed and saved on a different computer platform.

/PXSZ={*nx*, *ny*} Specifies the size of the averaging rectangle in pixels. Here *nx* is the number of rows and *ny* is the number of columns that are averaged to yield a single output pixel.

/RESL={*nx*, *ny*} Specifies resampling the full input image to an output image having *nx* rows by *ny* columns.

/S={*x0*,*dx*,*xn*,*y0*,*dy*,*yn*}
Calculates a bilinear interpolation of a subset of the source data. Here *x0* is the starting point in the X-direction, *dx* is the sampling increment, *xn* is the end point in the X-direction and the corresponding values for the Y-direction. If you can set *x0* equal to *xn* the operation will compute the triangulation but not the interpolation

/STW Saves the triangulation information in the wave W_TriangulationData in the current data folder. W_TriangulationData can only be used on the computer platform where it was created.

/SV Saves the Voronoi interpolation in the 2D wave M_VoronoiEdges, which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle containing the convex domain.

/TRNS={*transformFunc*,*p1*,*p2*,*p3*,*p4*}
Determines the mapping between a pixel in the destination image and the source pixel. *transformFunc* can be:

scaleShift Sets image scaling which could be anamorphic if the X and Y scaling are different.

radialPoly Corrects both color as well as barrel and pincushion distortion. In `radialPoly` the mapping from a destination pixel to a source pixel is a polynomial in the pixel's radius relative to the center of the image.

A source pixel, *sr*, satisfies the equation: $sr = a \cdot r + b \cdot r^2 + c \cdot r^3 + d \cdot r^4$, where *r* is the radius of a destination pixel having an origin at the center of the destination image.

The corresponding parameters are:

/U=*uniformScale* Calculates a bilinear interpolation of all the source data as with the /F flag but with two exceptions: A single uniform scale factor applies in both dimensions, and the scale factor applies to the number of points — not the intervals of the data.

transformFunc	*p1*	*p2*	*p3*	*p4*
scaleShift	xOffset	xScale	yOffset	yScale
radialPoly	a	b	c	d

/W={*xWave*, *yWave*} Provides the scaling waves for XYWaves interpolation. Both waves must be monotonic and must have one more point than the corresponding dimension in *srcWave*. The waves contain values corresponding to the edges of data points in *srcWave*, so that the X value at the first data point is equal to `(xWave[0]+xWave[1])/2`.

Flags for Warp

/dgrx=*wave* Sets the wave containing the destination grid X data.

/dgry=*wave* Sets the wave containing the destination grid Y data.

/sgrx=*wave* Sets the wave containing the source grid X data.

/sgry=*wave* Sets the wave containing the source grid Y data.

/WM=*im* Sets the interpolation method for warping an image.

I	Method
1	Fast selection of original data values.
2	Linear interpolation.
3	Smoothing interpolation (slow)

Details

When computing Bilinear or Spline interpolation *srcWave* can be a 2D or a 3D wave. When *srcWave* is a 3D wave the interpolation is computed on a layer by layer basis and the result is stored in a corresponding 3D wave. When the interpolation method is Kriging or Voronoi, *srcWave* is a 2D triplet wave (3-column wave) where each row specifies the X, Y, Z values of a datum. *srcWave* can be of any real data type. Results are stored in the wave M_InterpolatedImage. If *srcWave* is double precision so is M_InterpolatedImage; otherwise M_InterpolatedImage is a single precision wave.

ImageLineProfile

ImageLineProfile [***flags***] **xWave=*xwave*, yWave=*ywave*, srcWave=*srcWave* [, width=*value*, widthWave=*wWave*]**

The ImageLineProfile operation provides sampling of a source image along an arbitrary path specified by the two waves: *xWave* and *yWave*. The arbitrary path is made of line segments between every two consecutive vertices of *xWave* and *yWave*. In each segment the profile is calculated at a number of points (profile points) equivalent to the sampling density of the original image (unless the /V flag is used). Both *xWave* and *yWave* should have the same scaling as *srcWave*. If *srcWave* does not have the same scaling in both dimensions you should remove the scaling to compute an accurate profile.

At each profile point, the profile value is calculated by averaging samples along the normal to the profile line segment. The number of samples in the average is determined by the keyword width. The operation actually averages the interpolated values at N equidistant points on the normal to profile line segment, with `N=2(width+0.5)`. Samples outside the domain of the source image do not contribute to the profile value.

The profile values are stored in the wave W_ImageLineProfile. The actual locations of the profile points are stored in the waves W_LineProfileX and W_LineProfileY. When the averaging width is greater than zero, the operation can also calculate at each profile point the standard deviation of the values sampled for that

point (see /S flag). The results are then stored in the wave W_LineProfileStdv. When using this operation on 3D RGB images, the profile values are stored in the three-column waves M_ImageLineProfile and M_LineProfileStdv respectively.

Parameters

srcWave=*srcWave* Specifies the image for which the line profile is evaluated. The image may be a 2D wave of any type or a 3D wave or RGB data.

xWave=*xwave* Specifies the wave containing the x coordinate of the line segments along the path.

yWave=*ywave* Specifies the wave containing the y coordinate of the line segments along the path.

width=*value* Specifies the width (diameter) in pixels (need not be an integer value) in a direction perpendicular to the path over which the data is interpolated and averaged for each path point. If you do not specify width or use width=0, only the interpolated value at the path point is used.

widthWave=*wWave* Specifies the width of the profile (see definition above) on a segment by segment basis. *wWave* should be a 1D wave that has the same number of entries as xWave and yWave. If you provide a widthWave any value assigned with the width keyword is ignored. All values in the wave must be positive and finite.

Flags

/P=*plane* Specifies which plane (layer) of a 3D wave is to be profiled. By default *plane* =-1 and the profiles are of either the single layer of a 2D wave or all three layers of a 3D RGB wave. Use *plane* =-2 if you want to profile all layers of a 3D wave.

/S Calculates standard deviations for each profile point.

/SC Saves W_LineProfileX and W_LineProfileY using the X and Y scaling of *srcWave*.

/V Calculate profile points only at the vertices of xWave and yWave.

Examples

```
Make/N=(50, 50) sampleData
sampleData = sin((x-25) / 10) * cos((y-25) / 10)
NewImage sampleData
Make/n=2 xTrace={0,50} ,yTrace={20,20}
ImageLineProfile srcWave=sampleData, xWave=xTrace, yWave=yTrace
AppendtoGraph/T yTrace vs xTrace
Display W_ImageLineProfile
```

See Also

For additional examples see **ImageLineProfile** on page III-316.

ImageLoad

ImageLoad [***flags***] [***fileNameStr***]

The ImageLoad operation loads an image file into an Igor matrix wave. See the /T flag for a list of supported image file types.

ImageLoad requires QuickTime to load certain types of images.

Parameters

The file to be loaded is specified by *fileNameStr* and /P=*pathName* where pathName is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

On Macintosh, when loading a format that requires QuickTime, the name of the file to be loaded is limited to 31 characters because Igor calls Apple routines that have this limit.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-398 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter.

Flags

/C=*count* Specifies which images to load from a multi-image TIFF file. It loads and stores images as individual waves in the current data folder. By default, it loads only a single image

(i.e., /C=1). Use /C=-1 to load all images into a single 3D wave (images must be either 8-, 16-, or 32-bits/pixel for this option). If you specify a *count* that exceeds the number of images in the file, it will load all images beginning with the starting image. See also the /S flag and examples.

/G — Displays the loaded image.

/LR3D — Loads a partial range of a TIFF stack into a 3D wave (see also /C and /S).

/N=*baseName* — Stores the waves using *baseName* identically for the wave name. Only when *baseName* conflicts with an existing wave name will a numeric suffix be appended to the new wave names.

If you do not specify *baseName*, ImageLoad will use the name of the file as a base name.

/O — Overwrites an existing wave with the same name.

If /O is omitted and there is an existing wave with the same name, a numerical suffix will be appended to the image name.

/P=*pathName* — Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.

/Q — Quiet mode; suppresses insertion of loading info into the history area.

/RAT — Read All Tags reads all of the tags in a TIFF file into one or more waves. It creates a data folder named "Tag*n*" (with a numeric suffix, *n*, starting from zero) for each loaded image. When reading multiple images from a stack TIFF file it will create a corresponding number of data folders.

Each data folder contains a text wave named T_Tags, which contains 5 columns. The first row contains the offset of the current Image File Directory (IFD) from the start of the file. The remaining rows describe the individual TIFF Tags as they appear in the IFD.

The first column contains the tag number, the second contains the tag description, the third contains the tag type, the fourth contains the tag length, and the fifth contains either the value of the tag or a statement identifying the name of the wave in which the data was stored. For example, a simple tag that contains a single value has the form:

Num	Desc	Type	Length	Value
256	IMAGEWIDTH	4	1	2560

A tag that contains more data, such as an array of values has the form:

Num	Desc	Type	Length	Value
273	STRIPOFFSETS	4	-120	tifTag273

Here the Length field is negative (-1*realLength) and the Value field contains the name of the wave tifTag273 which contains the array of strip offsets.

When the Value field consists of ASCII characters it is stored in the T_Tags wave itself. All other types are stored in a wave in the same Tag data folder.

Private tags are usually designated by negative tag numbers. If their data type is anything other than ASCII, they are saved in separate waves.

/RTIO — Reads tag information only from a TIFF file. (This flag is similar to the /RAT flag but it does not load the images.) If you are loading a stack of images you can use the /C and /S flags to obtain tags from a specific range of images.

/T=*type* — Identifies what kind of image file to load. *type* is one of the following image file formats:

type	Loads this Image Format
any	Any graphic file type.
bmp	PC bitmap file.
gif	GIF file.
jpeg	JPEG file.
photoshop	PhotoShop file.

type	Loads this Image Format
pict	Macintosh picture file.
png	PNG file.
rpng	Raw PNG file (see **Details**).
sgi	Silicon Graphics file.
sunraster	Sun Raster file.
targa	Targa file.
tiff	Any TIFF file (see also **Special Notes Regarding TIFF Files**).

If you do not specify *type*, Igor will make a guess based on the file type (*Macintosh*) or file name extension (*Windows*). An error will be reported if Igor is unable to guess the image type.

/S=*start* Specifies the starting image in TIFF files that contain multiple images. By default, /S=0, so if you want to load all images just use /C=-1.

/Z no error reporting.

Details

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-34 for details.

ImageLoad sets the following variables:

`V_flag`	Set to 1 if the image was successfully loaded or to 0 otherwise.
`S_fileName`	Set to the name of the file that was loaded.
`V_numImages`	Set to the number of images in the file. Use this variable only with TIFF files.
`S_path`	Set to the file system path to the folder containing the file.
`S_waveNames`	Set to a semicolon-separated list of the names of loaded waves.

S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

When loading a rpng format PNG image, the wave will be either 8- or 16-bit unsigned integer format with 1 to 4 planes. PNG images with physical units will produce waves with X and Y units of meters. If a PNG image has a color table, ImageLoad will create two waves: a main image wave with 1 plane and a color table wave of the same name but with a "_pal" suffix (if the name is too long, it will create a wave named *PNG_pal* instead).

Special Notes Regarding TIFF Files

The ImageLoad operation reads data from the named TIFF file into waves. The operation supports 1-, 8-, 16- and 24-bit TIFF files. In case of 1-bit/pixel the data is converted into a 1 byte/pixel (/B/U wave). Images of 16-bits/pixel are read into /W/U waves. We note that 16-bit format is not part of the TIFF 6.0 specification but it is used extensively by scientific camera manufacturers. Images of 24-bits/pixel are read into 3D RGB waves.

When a TIFF file contains multiple images (stack), you can read all images into waves or you can specify a particular image or a range of images that you would like to read. To read the complete stack specify -1 as the image count and all images will be saved into a single 3D wave where each image is a sequential plane. This is appropriate only for images that are 8- or 16-bits/pixel deep. If the depth of the image is other than 8- or 16-bits/pixel you should read the images into separate waves.

If you have a TIFF file that is not read correctly by this operation (e.g., 4-bits/pixel), you may be able to read the file using QuickTime. To do so, make sure that the file name does not contain ".tif" or ".tiff" suffix (and on the Macintosh change its file type from `'TIFF'` to `'????'`). You can then load the file using the "Any" file designation and the file will be read by QuickTime resulting in an RGB image wave.

Examples

Reading TIFF files containing a stack of images:

```
Imageload /C=8/S=10/T=Tiff // Creates 8 waves starting from image #10 (zero based)
ImageLoad/C=-1/S=10/T=TIFF // Loads all the images ignoring the /S flag.
                           // The images are stored in a single 3D wave.
ImageLoad/C=-1/T=TIFF/RTIO // Does not load the images but reads all tags.
NewDataFolder/O/S tmp      // Gets the number of images and cleans up
ImageLoad/C=-1/T=TIFF/RTIO
```

```
Print V_numImages
KillDataFolder :
```

For loading graphic objects, see **Pictures** on page III-421. The **ImageSave** operation for saving waves as image files.

ImageMorphology

ImageMorphology [***flags***] ***Method imageMatrix***

The ImageMorphology operation performs one of several standard image morphology operations on the source *imageMatrix*. Unless the /O flag is specified, the resulting image is saved in the wave M_ImageMorph. The operation applies only to waves of type unsigned byte. All ImageMorphology methods except for watershed use a structure element. The structure element may be one of the built-in elements (see /E flag) or a user specified element.

Erosion, Dilation, Opening, and Closing are the only methods supported for a 3D *imageMatrix*.

Parameters

Method is one of the following names:

BinaryErosion	Erodes the source binary image using a built-in or user specified structure element (see /E and /S flags).
BinaryDilation	Dilates the source binary image using a built-in or user specified structure element (see /E and /S flags).
Closing	Performs the closing operation (dilation followed by erosion). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent, which means that there is no point of executing it more than once.
Dilation	Performs a dilation of the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.
Erosion	Erodes the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.
Opening	Performs an opening operation (erosion followed by dilation). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent which means that there is no point of executing it more than once.
TopHat	Calculates the difference between the eroded image and dilated image using the same structure element.
Watershed	Calculates the watershed regions for grayscale or binary image. Use the /N flag to mark all nonwatershed lines as NaNs. The /L flag switches from using 4 neighboring pixels (default) to 8 neighboring pixels.

Flags

/E=*id* Uses a particular built in structure element. The following are the built-in structure element. The following are the built-in structure elements; make sure to use the appropriate id for the dimensionality of *imageMatrix*:

id	Element	Origin	Shape
1	2x2	(0,0)	square (default)
2	1x3	(1,1)	row (in 3x3 square)
3	3x1	(1,1)	column (in 3x3 square)
4	3x3	(1,1)	cross (in 3x3 square)
5	5x5	(2,2)	circle (in 5x5 square)
6	3x3	(1,1)	full 3x3 square
200	2x2x2	(1,1,1)	symmetric cube
202	2x2x2	(1,1,1)	2 voxel column in Y direction

id	Element	Origin	Shape
203	2x2x2	(1,1,1)	2 voxel column in X direction
204	2x2x2	(1,1,1)	2 voxel column in Z direction
205	2x2x2	(1,1,1)	XY plane
206	2x2x2	(1,1,1)	YZ plane
207	2x2x2	(1,1,1)	XZ plane
300	3x3x3	(1,1,1)	symmetric cube
301	3x3x3	(1,1,1)	symmetric ball
302	3x3x3	(1,1,1)	3 voxel column in Y direction
303	3x3x3	(1,1,1)	3 voxel column in X direction
304	3x3x3	(1,1,1)	3 voxel column in Z direction
305	3x3x3	(1,1,1)	XY plane
306	3x3x3	(1,1,1)	YZ plane
307	3x3x3	(1,1,1)	XY plane
500	5x5x5	(2,2,2)	symmetric cube
501	5x5x5	(2,2,2)	symmetric ball
700	7x7x7	(3,3,3)	symmetric cube
701	7x7x7	(3,3,3)	symmetric ball

Note that this flag has no effect on watershed calculations.

/I= *iterations* Repeats the operation the specified number of *iterations*.

/L Uses 8-connected neighbors instead of 4.

/N Sets the background level to 64 (= NaN).

/O Overwrites the source wave with the output.

/R=*roiSpec* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose values are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape. See **ImageGenerateROIMask** for more information on creating ROI waves.

In general, the *roiSpec* has the form {*roiWaveName*, *roiFlag*}, where *roiFlag* can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.

roiFlag=1: Set pixels outside the ROI as in original image.

roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default *roiFlag* is set to 1 and it is then possible to use the /R flag using the abbreviated form /R=*roiWave*.

/S= *seWave* Specifies your own structure element.

seWave must be of type unsigned byte with pixels that belong to the structure element set to 1 and background pixels set to 0.

There are no limitations on the size of the structure element and you can use the /X and /Y flags to specify the origin of your structure element.

/W= *whiteVal* Sets the white value in the binary image if it is different than 255. The black level is assumed to be zero.

/X= *xOrigin* Specifies the X-origin of a user-defined structure element starting at 0. If you do not use this flag Igor sets the origin to the center of the specified structure element.

/Y= *yOrigin* Specifies the Y-origin of a user defined structure element starting at 0. If you do not use this flag Igor sets the origin to the center of the specified structure element.

/Z= *zOrigin* Specifies the Z-origin of the element for 3D structure elements. If you do not use this flag Igor sets the origin to the center of the specified structure element.

Examples

If you would like to apply a morphological operation to a wave whose data type is not an unsigned byte and you wish to retain the wave's dynamic range, you can use the following approach:

```
Function ScaledErosion(inWave)
   Wave inWave

   WaveStats/Q inWave
   Variable nor=255/(V_max-V_min)
   MatrixOp/O tmp=nor*(inWave-V_min)
   Redimension/B/U tmp
   ImageMorphology/E=5 Erosion tmp
   Wave M_ImageMorph
   MatrixOp/O inWave=(M_ImageMorph/nor)+V_min
   KillWaves/Z tmp,M_ImageMorph
End
```

See Also

The **ImageGenerateROIMask** operation for creating ROIs. For details and usage examples see **Morphological Operations** on page III-312 and **Particle Analysis** on page III-319.

ImageNameList

ImageNameList(*graphNameStr, separatorStr*)

The ImageNameList function returns a string containing a list of image names in the graph window or subwindow identified by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

separatorStr should contain a single character such as "," or ";" to separate the names.

An image name is defined as the name of the 2D wave that defines the image with an optional #ddd suffix that distinguishes between two or more images that have the same wave name. Since the image name has to be parsed, it is quoted if necessary.

Examples

The following command lines create a very unlikely image display. If you did this, you would want to put each image on different axes, and arrange the axes such that they don't overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack,'jack # 2';
Display;AppendImage jack
AppendImage/T/R jack
AppendImage 'jack # 2'
AppendImage/T/R 'jack # 2'
Print ImageNameList("",";")
```

prints jack;jack#1;'jack # 2';'jack # 2'#1;

See Also

Another command related to images and waves: **ImageNameToWaveRef**.

For commands referencing other waves in a graph: **TraceNameList**, **WaveRefIndexed**, **XWaveRefFromTrace**, **TraceNameToWaveRef**, **CsrWaveRef**, **CsrXWaveRef**, **ContourNameList**, and **ContourNameToWaveRef**.

ImageNameToWaveRef

ImageNameToWaveRef(*graphNameStr, imageNameStr*)

The ImageNameToWaveRef function returns a wave reference to the 2D wave corresponding to the given image name in the graph window or subwindow named by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

The image is identified by the string in *imageNameStr*, which could be a string determined using **ImageNameList**. Note that the same image name can refer to different waves in different graphs.

For a discussion of wave references, see **Wave Reference Functions** on page IV-173.

ImageRegistration

ImageRegistration [*flags*] **[testMask=***testMaskWave***] [refMask=***refMaskWave***] testWave=***imageWave1***, refWave=***imageWave2***

The ImageRegistration operation adjusts the test image wave, testWave, to match the reference image wave, refWave, possibly subject to auxiliary mask waves. The registration may involve offset, rotation, scaling or skewing.

Image data may be in two or three dimensions.

ImageRegistration is designed to find accurate registration for relatively small variation on the order of a few degrees of rotation and a few pixels offset between the reference and test images.

All the input waves are expected to be single precision float (SP) so you may have to redimension your images before using ImageRegistration.

ImageRegistration does not tolerate NaNs or INFs; use the masks if you need to exclude pixels from the registration process.

Parameters

refMask=*refMaskWave* Specifies an optional ROI wave used to mask refWave. Omit refMask to use all of the refWave.

The wave must have the same dimensions as refWave. refMask is a single precision floating point wave with nonzero entries marking the "ON" state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.

refWave=*imageWave2* Specifies the name of the reference image wave used to adjust testWave.

testMask=*testMaskWave* Specifies an optional ROI wave used to mask testWave. Omit testMask to use all of the testWave.

The wave must have the same dimensions as refWave. testMask is a single precision floating point wave with nonzero entries marking the "ON" state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.

testWave=*imageWave1* Specifies the name of the image wave that will be adjusted to match refWave.

testMaskWave and *refMaskWave* are optional ROI waves. The waves must have the same dimensions as testWave and refWave respectively. They must be single precision floating point waves with nonzero entries marking the "ON" state. If you need to include the whole region described by testWave or the whole region described by refWave you can omit the respective mask wave

Flags

/ASTP=*val* Sets the adaptation step for the Levenberg-Marquardt algorithm. Default value is 4.

/BVAL=*val* Enables clipping and sets the background values to which masked out voxels of the test data will be set.

/CONV=*val* Sets the convergence method.

val=0: Gravity, use if the difference between the images is only in translation. This option is frequently useful as a first step when the test and reference data are too far apart for accurate registration. The result of this registration is then passed to a subsequent ImageRegistration with /CONV=1.

val=1: Marquardt.

/CSNR=*val* Determines if the operation calculates the signal to noise ratio (SNR).

val=0: The SNR is not calculated.

val=1: The SNR is calculated (default).

Skipping the SNR calculation saves time and may be particularly useful when performing the registration on a stack of images.

/FLVL=*val* Specifies the finest level on which the optimization is to be performed.

If this is the same as /PRDL, then only the coarsest registration calculation is done.

If /FLVL=1 (default), then the full multiresolution pyramid is processed. You can use this flag to terminate the computation at a specified coarseness level greater than 1.

/GRYM Optimizes the gray level scaling factor.

It is sometimes dangerous to let the program adjust for gray levels because in some situations it might result in a null image.

/GRYR Renders output using the gray scaling parameter. This is more meaningful if the operation computes the optimal gray scaling (see /GRYM).

/GWDT={*sx*,*sy*,*sz*} Sets the three fields to the half-width of a Gaussian window that is used to smooth the data when computing the default masks. Defaults are {1,1,1}. See /REFM and /TSTM for more details.

/INTR=*val* Sets the interpolation method.

val=0: Nearest neighbor. Used when registering the center of gravity of the test and reference images.

val=1: Trilinear.

val=2: Tricubic (default).

/ISOS Optimizes the isometric scaling. This option is inappropriate if voxels are not cubic.

/ISR Computes the multiresolution pyramid with isotropic size reduction.

If the flag is not specified, the size reduction is in the XY plane only.

/MING=*val* Sets the minimum gain at which the computations will stop. Default value is zero, but you can use a slightly larger value to stop the iterations earlier.

/MSKC=*val* Sets mask combination value. During computation the masks for the test data and the mask for the reference data are also transformed. This flag determines how the two masks are to be combined. The registration criteria are computed for the combination of the two masks.

val=0: or.

val=1: nor.

val=2: and (default).

val=3: nand.

val=4: xor.

val=5: nxor.

/PRDL=*depth* Specifies the depth of the multiresolution pyramid. The finest level is *depth*=1. Each level of the pyramid decreases the resolution by a factor of 2. By default, the pyramid *depth*=4, which corresponds to a resolution reduction by a factor of $2^{(depth-1)}=8$.

The algorithm starts by computing the first registration on large scale features in the image (deepest level of the pyramid). It then makes small corrections to the registration at each consecutive pyramid level.

For best results, the coarsest representation the data should be between 30 and 60 pixels on a side. For example, for an image that is *H* by *V* pixels, you should choose the depth such that $H/2^{(depth-1)} \approx 30$.

/PSTK When performing registration of a stack of images, use this flag to apply the registration parameters of the previous layer as the initial guess for the registration of each layer after the first in the 3D stack.

/Q Quiet mode; no messages printed in the history window.

/REFM=*val* Sets the reference mask.

val=0: To leave blank and then every pixel is taken into account.

val=1: Value will be set if a valid reference mask is provided.

val=2: The reference mask is computed (default).

When computing the reference mask it is assumed that brighter features are more important. This is done by using a low pass filter on the data (using the parameters in /GWDT) which is then converted into a binary mask. Note that you do not need to specify /REFM=1 if you are providing a reference mask wave. See also /TSTM.

/ROT={*rotX*,*rotY*,*rotZ*}

Determines if optimization will take into account rotation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding rotation parameter. Defaults are {0,0,1}, which are the appropriate for rotating images.

/SKEW={*skewX*,*skewY*,*skewZ*}

Determines if optimization will take into account skewness about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding skewness parameter. Defaults are {0,0,0}. Note that skewing and rotation or isometric scaling are mutually exclusive operations.

/STCK Use /STCK to perform the registration between a 2D reference image and each of the layers in a 3D image. The number of rows and columns of the refWave must match exactly the number of rows and columns in testWave. The transformation parameters are saved in the wave M_RegParams where each column contains the parameters for the corresponding layer in testWave.

/STRT=*val* Sets the first value of the adaptation parameter in the Levenberg-Marquardt algorithm.

The default value of this parameter is 1.

/TRNS={*transX*,*transY*,*transZ*}

Determines if optimization will take into account translation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding translation parameter. Defaults are {1,1,0}, which are appropriate for finding the X and Y translations of an image.

/TSTM=*val* Sets the test mask.

val=0: To leave blank and then every pixel is taken into account.

val=1: This value will be set if a valid reference mask is provided.

val=2: The reference mask is computed. This is the default value.

The test image mask is computed in the same way as the reference image mask (see /REFM) using the same set of smoothing parameters. Note that you do not need to specify /TSTM=1 if you are providing a test mask wave.

/USER=*pWave* Provides a user transformation that will be applied to the input testWave in order to create the trasnsformed image. *pWave* must be a double precision wave which contains the same number of rows as W_RegParams.

Note: If you use a previously created W_RegParams make sure to change its name as it is overwritten by the operation.

If *pWave* has only one column and testWave contains multiple layers, then the same transformation applies to all layers. If *pWave* contains more than one column, then each layer of testWave is processed with corresponding column. If there are more layers than columns the first column is used in place of the missing columns.

/ZMAN Modifies the test and reference data by subtracting their mean values prior to optimization.

Details

ImageRegistration will register images that have sufficiently similar features. It will not work if key features are too different. For example, ImageRegistration can handle two images that are rotated relative to each other by a few degrees, but cannot register images if the relative rotation is as large as 45 degrees. The algorithm is capable of subpixel resolution but it does not handle large variations between the test image and the reference image. If the centers of the two images are too far from each other, you should first try ImageRegistration using /CON=0 to remove the translation offset before proceeding with a finer registration of details.

The algorithm is based on an iterative processing that proceeds from coarse to fine detail. Optimization uses a modified Levenberg-Marquardt algorithm and produces an affine transformation for the relative rotation

and translation as well as for isometric scaling and contrast adjustment. The algorithm is most effective with square images where the center of rotation is not far from the center of the image.

When using gravity for convergence, skew parameters can't be evaluated (only translation is supported). Skew and isoscaling are mutually exclusive options. Mask waves are defined to have zero entries for pixels outside the region of interest and nonzero entries otherwise. If a mask is not provided, every pixel is used.

ImageRegistration creates the waves M_RegOut and M_RegMaskOut, which are both single precision waves. In addition, the operation creates the wave W_RegParams which stores 20 double precision registration parameters. M_RegOut contains the transformed (registered) test image and M_RegMaskOut contains the transformed mask (which is not affected by mask combination). ImageRegistration ignores wave scaling; images are compared and registered based on pixel values only.

The results printed in the history include:

dx, dy, dz	translation offsets measured in pixels.
a*ij*	Elements in the skewing transformation matrix.
phi	Rotation angle in degrees about the X-axis. Zero for 2D waves.
tht	Rotation angle in degrees about the Y-axis. Zero for 2D waves.
psi	Rotation angle in degrees about the Z-axis.
det	Absolute value of determinant of the skewing matrix (a*ij*).
err	Mean square error defined as $\frac{1}{N}\sum(x_i - y_i)^2$, where x_i is the original pixel value, y_i the computed value, and N is the number of pixels.
snr	Signal to noise ratio in dB. It is given by: $10 \cdot \log\left(\frac{\sum inVal^2}{\sum(x_i - y_i)^2}\right)$.

These parameters are stored in the wave W_RegParams (or M_RegParams in the case of registering a stack). Dimension labels are used to describe the contents of each row of the output wave. Each column of the wave consists of the following rows (also indicated by dimension labels):

Point	Contents	Point	Contents	Point	Contents	Point	Content
0	dx	6	a21	12	gamma	17	origin_x
1	dy	7	a22	13	phi	18	origin_y
2	dz	8	a23	14	theta	19	origin_z
3	a11	9	a31	15	psi	21	MSE
4	a12	10	a32	16	lambda	21	SNR
5	a13	11	a33				

You can view the output waves with dimension labels by executing:

```
Edit W_RegParams.ld
```

References

The ImageRegistration operation is based on an algorithm described by:

Thévenaz, P., and M. Unser, A Pyramid Approach to Subpixel Registration Based on Intensity, *IEEE Transactions on Image Processing*, *7*, 27-41, 1998.

ImageRemoveBackground

ImageRemoveBackground /R=*roiWave* [*flags*] *srcWave*

The ImageRemoveBackground operation removes a general background level, described by a polynomial of a specified order, from the image in *srcWave*. The result of the operation are stored in the wave M_RemovedBackground.

Flags

/F — Computes only the background surface fit. Will only store the resulting fit in M_RemovedBackground. This will not subtract the fit from the image.

/O — overwrites the original wave.

/P=*polynomial order* — Specifies the order of the polynomial fit to the background surface. If omitted, the order is assumed to be 1.

/R=*roiWave* — Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u), which has the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See **ImageGenerateROIMask** for more information on creating ROI waves.

/W — Specifies that polynomial coefficients are to be saved in the wave W_BackgroundCoeff.

Details

The identification of the background is done via the ROI wave. The ROI waves should consist of the value 1 where the user wants to designate a pixel as a background and 0 otherwise.

The operation first performs a polynomial fit to the points designated by the ROI wave using the specified polynomial order. A polynomial of order N corresponds to the function:

$$F_N(x,y) = \sum_{m=0}^{N} \sum_{n=0}^{m} c_{nm} x^{m-n} y^{n} .$$

Using the polynomial fit, a surface corresponding to the polynomial is subtracted from the source wave and the result is saved in M_RemovedBackground, unless the /O flag is used, in which case the original wave is overwritten.

Use the /W flag if you want polynomial coefficients to be saved in the W_BackgroundCoeff wave. Coefficients are stored in the same order as the terms in the sums above.

If you do not specify the polynomial order using the /P flag, the default order is 1, which means that the operation subtracts a plane (fitted to the ROI data) from the source image.

Note, if the image is stored as a wave of unsigned byte, short, or long, you might consider converting it into single precision (using `Redimension/S`) before removing the background. To see why this is important, consider an image containing a region of pixels equal to zero and subtracting a background plane corresponding to a nonconstant value. After subtraction, at least some of the pixels in the zero region should become negative, but because they are stored as unsigned quantities, they appear incorrectly as large values.

See Also

The **ImageGenerateROIMask** operation for creating ROIs. For examples see **Background Removal** on page III-323.

ImageRestore

ImageRestore [*flags*] srcWave=*wSrc*, psfWave=*wPSF* [, relaxationGamma=*h*, startingImage=*wRecon*]

The ImageRestore operation performs the Richardson-Lucy iterative image restoration.

Flags

/DEST=*destWave* — Specifies the desired output wave.
If /DEST is omitted, the output from the operation is stored in the wave M_Reconstructed in the current data folder.

/ITER=*iterations* — Specifies the number of iterations. The default number of iterations is 100.

/Z Do not report errors.

Parameters

psfWave=*wPSF* Specifies a known point spread function. *wPSF* must be a 2D (square NxN) wave of the same numeric type as *wSRC*. N must be an odd number greater than 1.

relaxationGamma=*h* Specifies positive power gamma of in the relaxation mapping (see Details).

startingImage=*wRecon* Use this keyword to specify a starting image that could be for example the output from a previous call to this operation. *wRecon* must have the same dimensions as *wSRC* and the same numeric type.

You must make sure that *wRecon* is not the user-specified or the default destination wave of the operation.

srcWave=*wSrc* Specifies the degraded image which must be a 2D single-precision or double-precision real wave.

Details

ImageRestore performs the Richardson-Lucy iteration solution to the deconvolution of an image. The input consists of the degraded image and point spread function as well as the desired number of iterations.

The operation allows you to apply additional iterations by setting the starting image to the restored output wave from a previous call to ImageRestore using the startingImage keyword. If startingImage is omitted, the starting image is created by ImageRestore with each pixel set to the value 1.

In the case of stellar images it may be useful to apply a relaxation step that involves scaling the correction evaluated at each iteration by

$$factor(v) = \sin\left(\frac{\pi}{2}\frac{v - v_{\min}}{v_{\max} - v_{\min}}\right)^{\gamma},$$

where v is pixel value, vmax and vmin are the maximum and minimum level pixels in the image and gamma is the user-specified relaxationGamma.

ImageRotate

**`ImageRotate [`*`flags`*`] `*`imageMatrix`*

The ImageRotate operation rotates the image clockwise by *angle* (degrees) or counter-clockwise if /W is used.

The resulting image is saved in the wave M_RotatedImage unless the /O flag is specified. The size of the resulting image depends on the angle of rotation.

The portions of the image corresponding to points outside the domain of the original image are set to the default value 64 or the value specified by the /E flag.

You can apply ImageRotate to 2D and 3D waves of any data type.

Flags

/A=*angle* Specifies the rotation angle measured in degrees in a clockwise direction. For rotations by exactly 90 degrees use /C or /W instead.

/C Specifies clockwise rotation.

Clockwise is the default direction so the rotation will be clockwise whether you use /C or not, so long as you do not use /W.

/E= *val* Specifies the value for pixels that are outside the domain of the original image. By default pixels are set to 64. If you specify `/E=(NaN)` and your data is of type char, short, or long, the operation sets the external values to 64.

/F Rotates image by 180 degrees.

/H	Flip the image horizontally.
/O	Overwrites the original image with the rotated image.
/Q	Quiet mode. Without this flag the operation writes warnings in the history window.
/S	Uses source image wave scaling to preserve scaling and relative locations of objects in the image for rotation angles that are multiples of 90 degrees.
/V	Flip the image vertically.
/W	Specifies counter-clockwise rotation.
/Z	Ignore errors.

See Also

The **MatrixTranspose** operation.

ImageSave

ImageSave [***flags***] ***waveName*** [[**as**]***fileNameStr***]

The ImageSave operation saves the named wave as an image file.

ImageSave requires that QuickTime be installed when saving formats other than TIFF and raw PNG.

To make your command more portable, we recommend using the /IGOR flag which tells ImageSave to use internal Igor routines rather than QuickTime, if possible. Currently this flag affects the TIFF format only.

Parameters

The file to be written is specified by *fileNameStr* and /P=*pathName* where pathName is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

On Macintosh, when saving in a format that requires QuickTime, the name of the file to be written is limited to 31 characters because Igor calls Apple routines that have this limit.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-398 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter or specify "" for *fileNameStr* or use the /I flag. The "as" keyword before *fileNameStr* is optional.

Flags

/D=*depth*	Specifies color depth in bits-per-pixel. Integer values of 1, 8, 16, 24, 32, and 40 are supported. A *depth* of 40 specifies 8-bit grayscale; a *depth* of 8 saves the file as 8-bits/pixel with a color lookup table. If /D is omitted, it acts like /D=8. Saving with a color table may cause some loss of fidelity. See also the discussion of saving TIFF files below.
/F	Saves the wave as single precision float. The data is not normalized. Applies only to TIFF files.
/I	Interactive mode. Forces ImageSave to display a Save File dialog, even if the file and folder location are fully specified.
/IGOR	Tells ImageSave to use Igor's internal code if possible. This flag is recommended to create a command that works if QuickTime is not available. /IGOR currently affects saving as TIFF only. The /S, /U and /WT flags also force the use of Igor's internal code.
/O	Overwrites the specified file if it exists. If /O is omitted and the file exists, ImageSave displays a Save File dialog.
/P=*pathName*	Specifies the folder in which to save the image file. *pathName* is the name of an existing symbolic path.
/Q=*quality*	Specifies the quality of the compressed image. *quality* is a number between 0 and 1, with 1 being the highest quality. This is only applicable when saving in formats with lossy compression like JPEG.
/S	Saves as stack. Applies only to 3D or 4D source waves saved as TIFF files.

/T=*fileTypeStr* Specifies the type of file to be saved.

fileTypeStr	Saved Image Format
"photoshop"	PhotoShop file
"bmp"	PC bitmap file
"jpeg"	JPEG file
"pict"	Macintosh picture file
"png"	PNG file
"rpng"	raw PNG file (see **Saving as Raw PNG**)
"sgi"	Silicon Graphics file
"targa"	Targa file
"tiff"	TIFF file

The default file types, used if /T is omitted, are "pict" on the Macintosh and "bmp" on Windows.

/U Prevents normalization. This works when saving TIFF only. See **Normalization** below.

/WT=*tagWave* Saves TIFF files with file tags as specified by *tagWave*, which is a text wave consisting of a row and 5 columns for each tag (see description of the /RAT flag under **ImageLoad**). It ignores any information in the second column but will write the tags sequentially (only in the first Image File Directory (IFD) if there is more than one image). If the fourth column contains a negative number, there must be a wave, whose name is given in the fifth column of *tagWave*, in the same data folder as *tagWave*. You must make sure that: (1) tag numbers are legal and do not conflict with any existing tags; (2) the data type and data size are consistent with the amount of data saved in external waves.

/Z No error reporting.

Saving as Raw PNG

The rpng image format requires a wave in 8- or 16-bit unsigned integer format with 1 to 4 layers. Use one layer for grayscale, 3 layers for rgb color, and the extra layer for an alpha channel. If X or Y scaling is not unity, they both must be valid and must be either inches per pixel or meters per pixel. If the units are not inches they are taken to be meters.

Normalization

Depending on the data type of your wave and the depth of the image file being created, ImageSave may save a "normalized" version of your data. The normalized version is scaled to fit in the range of the image file data type. For example, if you save a 16-bit Igor wave containing pixel values from -1000 to +1000 in an 8-bit grayscale TIFF file, ImageSave will map the wave values -1000 and +1000 to the file values 0 and 255 respectively.

When saving as greater than 8 bits, Igor normalizes to 65535 as the full-scale value.

When saving as floating point, no normalization is done. Normalization is also not done when saving 8-bit wave data to an 8-bit image file.

The /U flag disables normalization but works only when saving as TIFF.

If you use the /U flag, Igor will save unnormalized data. If the wave data exceeds the range supported by the file data format, the saved file data will be invalid.

Saving as TIFF

Igor can create four different categories of TIFF files:

Grayscale image

Grayscale image with color table (requires QuickTime)

RGB image (red, green and blue components for each pixel)

Stack of grayscale images

Which ImageSave flags you need to use depends on the nature of your data and on your goal, as described in the following sections.

Saving a Simple 2D Wave as TIFF

If your Igor data is in the form of a simple 2D wave, you can save it as a grayscale image with or without a color table.

Use /D=8 to save as 8 bits with a color table. Normalization is done except if the wave data is 8 bits. This requires QuickTime - do not use the /IGOR flag. The colors in the color table will all be shades of gray.

Use /D=40 to save as 8 bits without a color table. Normalization is done except if the wave data is 8 bits.

Use /D=16 to save as 16 bits with normalization.

Use /F to save as single-precision floating point without normalization. Many programs can not read this format.

Use /U to prevent normalization.

Use /IGOR to guarantee that Igor's internal TIFF routines will be used rather than QuickTime. Igor's internal routines do not save color tables.

Saving an Igor RGB Wave as TIFF

If your Igor data is an RGB wave (a 3D wave with exactly 3 layers), you can save it as an RGB image, a grayscale image or a grayscale image with a color table.

When saving as RGB, ImageSave does not perform normalization. However, if the wave data type is greater than 8 bits and you are saving to 8 bits, ImageSave divides the wave data by 256. No other normalization or scaling is done.

Use /D=8 to save as a grayscale image with a color table. Normalization is done except if the wave data is 8 bits. This requires QuickTime - do not use the /IGOR flag.

Use /D=40 to save as grayscale image without a color table. Normalization is done except if the wave data is 8 bits.

Without /D=8 or /D=40, the data is saved as RGB (three components per pixel - one for red, one for green and one for blue). The rest of this section applies when saving as RGB only.

Use /D=24 or /D=32 to save as 24 bits-per-pixel (8 bits-per-component) without normalization.

Use /D=16 to save as 48 bits-per-pixel (16 bits-per-component) without normalization.

Use /F to save as 96 bits-per-pixel (32 bits-per-component) without normalization. Many programs can not read this format.

Use /U to prevent normalization.

Saving 3D or 4D Waves as a Stack of TIFF Images

If your Igor data is a 3D wave other than an RGB wave or a 4D wave, you can save it as a stack of grayscale images without a color map.

Use /S to indicate that you want to save a stack of images rather than a single image from the first layer of the wave.

Use /D=8 to save as 8 bits. Normalization is done except if the wave data is 8 bits.

Use /D=16 to save as 16 bits with normalization.

Use /F to save as single-precision floating point without normalization. Many programs can not read this format.

Use /U to prevent normalization.

Stacked images are normalized on a layer by layer basis. If you want to have uniform scaling and normalization you should convert your wave to the file data type before executing ImageSave.

The **ImageLoad** operation for loading image files into waves.

ImageSeedFill

ImageSeedFill [*flags*] [*keyword*], **seedX=***xLoc*, **seedY=***yLoc*, **target=***setValue*, **srcWave=***srcImage*

The ImageSeedFill operation takes a seed pixel and fills a contiguous region with the target value, storing the result in the wave M_SeedFill. The filled region is defined by all contiguous pixels that include the seed

pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). ImageSeedFill works on 2D and 3D waves.

Parameters

keyword is one of the following names:

adaptive=*factor* Invokes the adaptive algorithm where a pixel or voxel is accepted if, in addition, its value satisfies: $|val - avg| < factor \cdot stdv$.

Here *val* is the value of the pixel or voxel in question, *avg* is the average value of the pixels or voxels in the neighborhood and *stdv* is the standard deviation of these values. By choosing a small *factor* you can constrain the acceptable values to be very close to the neighborhood average. A large *factor* allows for more deviation assuming that the *stdv* is greater than zero.

This requirement means that a connected pixel has to be between the specified minimum and maximum value **and** satisfy the adaptive relationship. In most situations it is best to set wide limits on the minimum and maximum values and allow the adaptive parameter to control the local connectivity.

fillNumber=*num* Specifies the number, in the range 1 to 26, of voxels in each 3x3x3 cube that belong to the set. If fillNumber is exceeded, the operation fills the remaining members of the cube. If you do not specify this keyword, the operation does not fill the cube. Used only in the fuzzy algorithm.

fuzzyCenter=*fcVal* Specifies the center value for the fuzzy probability with the fuzzy algorithm (see **Details**). The default value is 0.25. Its standard range is 0 to 0.5, although interesting results might be obtained outside this range.

fuzzyProb=*fpVal* Specifies a probability threshold that must be met by a voxel to be accepted to the seeded set. The value must be in the range 0 to 1. The default value is 0.75.

fuzzyScale=*fsVal* Determines if a voxel is to be considered in a second stage using fuzzy probability. *fsVal* must be nonzero in order to invoke the fuzzy algorithm. The scale is used in comparing the value of the voxel to the value of the seed voxel. The scale should normally be in the range 0.5 to 2.0.

fuzzyWidth=*fwVal* Defines the width of the fuzzy probability distribution with the fuzzy algorithm (see **Details**). In most situations you should not need to specify this parameter. The default value is 1.

min=*minval* Specifies the minimum value that is accepted in the seeded set. Not needed when using fuzzy algorithm.

max=*maxval* Specifies the maximum value that is accepted to the seeded set. Not needed when using the fuzzy algorithm.

seedP=row Specifies the integer row location of the seed pixel or voxel. This avoids roundoff issues when srcWave has wave scaling. You must provide either seedP or seedX with all algorithms. It is sometimes convenient to use this with cursors e.g., `seedP=pcsr(a)`.

seedQ=col Specifies the integer column location of the seed pixel or voxel. This avoids roundoff difficulties when srcWave has wave scaling. You must provide either seedQ or seedY with all algorithms.

seedR=layer Specifies the integer layer position of the seed voxel. When srcWave is a 3D wave you must use either seedR or seedZ.

seedX=*xLoc* Specifies the pixel or voxel index. If srcWave has wave scaling, seedX must be expressed in terms of the scaled coordinate. This keyword or seedP is required with all algorithms.

seedY=*yLoc* Specifies the pixel or voxel index. If srcWave has wave scaling, seedY must be expressed in terms of the scaled coordinate. This keyword or seedQ is required with all algorithms.

seedZ=*zLoc* Specifies the voxel index. If srcWave has wave scaling, seedZ must be expressed in terms of the scaled coordinate. You must use this keyword or seedR whenever srcWave is 3D.

srcWave=*srcImage* Specifies the source image wave.

target=*val* Sets the value assigned to pixels or voxels that belonging to the seeded set.

Flags

/B=*bValue* Specifies the value assigned to pixels or voxels that do not belong to the fuzzy set.

/C	Uses 8-connectivity where a pixel can be connected to any one of its neighbors and with which it shares as little as a single boundary point. The default setting is 4-connectivity where pixels can be connected if they are neighbors along a row or a column. This has no effect in 3D, where 26-connectivity is the only option.
/K=*killCount*	Terminates the fill operation after *killCount* elements have been accepted.
/O	Overwrites the source wave with the output (2D only).
/R=*roiWave*	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u), that has the same number of rows and columns and layers as the image wave. The ROI itself is defined by the entries/pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See ImageGenerateROIMask for more information on creating ROI waves.

Details

In two dimensions, the operation takes a seed pixel, optional minimum and maximum pixel values and optional adaptive coefficient. It then fills a contiguous region (in a copy of the source image) with the target value. There are two algorithms for 2D seed fill. In direct seed fill (only min, max, seedX and seedY are specified) the filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). In adaptive fill, there is an additional condition for the pixel or voxel to be selected, which requires that the pixel value must be within the standard deviation of the average in the 3x3 (2D) or 3x3x3 (3D) nearest neighbors. If you do not specify the minimum and maximum values then the operation selects only values identical to that of the seed pixel.

In 3D, there are three available algorithms. The direct seed fill algorithm uses the limits specified by the user to fill the seeded domain. In adaptive seed fill the algorithm requires the limits as well as the adaptive parameter. It fills the domain by accepting only voxels that lie within the adaptive factor times the standard deviation of the immediate voxel neighborhood. To invoke the third algorithm you must set fuzzyScale to a nonzero value. The fuzzy seed fill uses two steps to determine if a voxel should be in the filled domain. In the first step the value of the voxel is compared to the seed value using the fuzzy scale. If accepted, it passes to the second stage where a fuzzy probability is calculated based on the number of voxels in the 3x3x3 cell which passed the first step together with the user-specified probability center (fuzzyCenter) and width (fuzzyWidth). If the result is greater than fuzzyProb, the voxel is set to belong to the filled domain.

If the /O flag is not specified, the result is stored in the wave M_SeedFill.

If you specify a background value with the /B flag, the resulting image consists of the background value and the target value in the area corresponding to the seed fill. Although the wave is now bi-level, it retains the same number type as the source image.

ImageSeedFill returns a "bad seed pixel specification" if the seed pixel location derived from the various keywords above satisfies one or more of the following conditions:

1. The computed integer pixel/voxel is outside the image.
2. The value stored in the computed integer pixel/voxel location does not satisfy the min/max or fuzzy conditions. This is the most common condition when srcWave has wave scaling. To avoid this difficulty you should use the keywords seedP, seedQ, and seedR.

Examples

Using Cursor A position and value to supply parameter inputs for a 2D seedFill (**Warning**: command wrapped over two lines):

```
ImageSeedFill
seedP=pcsr(a),seedQ=qcsr(a),min=zcsr(a),max=zcsr(a),target=0,srcwave=image0
```

Using the fuzzy algorithm for a 3D wave (**Warning**: command wrapped over two lines):

```
ImageSeedFill seedX=232,seedY=175,seedZ=42,target=1,fillnumber=10,fuzzycenter=.25,
fuzzywidth=1,threshold=1,fuzzyprob=0.4,srcWave=ddd
```

See Also

For an additional example see **Seed Fill** on page III-321. To display the result of the operation for 3D waves it is useful to convert the 3D wave M_SeedFill into an array of quads. See **ImageTransform vol2surf**.

ImageSnake

ImageSnake [***flags***] ***srcWave***

The ImageSnake operation creates or modifies an active contour/snake in the grayscale image srcWave. The operation iterates to find the "lowest total energy" snake. The energy is defined by a range of optional flags,

each corresponding to an individual term in the total energy expression. Iterations terminate by reaching the maximum number of iterations, when the snake does not move between iterations or when the user aborts the operation.

Flags

/ALPH=*alpha* Sets the coefficient of the energy term arising from the "tightness" of the snake.

/BETA=*beta* Sets the coefficient of the energy term corresponding to curvature of the snake. A high value for beta makes the snake more rounded.

/DELT=*delta* Sets the coefficient of the repulsion energy. A high value of *delta* keeps nonconsecutive snake points far from each other.

/EPS=*num* Sets the maximum number of vertices which are allowed to move in one iteration. If the number of vertices which move during an iteration is smaller than *num* then iterations terminate.

/EXEF=*eta* Sets the coefficient of the optional external energy component. By default this value is set to zero and there is no external energy contribution to the snakes energy. Note, this component is referred to as "external" because it is completely up to the user to specify both its coefficient and the value associated with each pixel. It should not be confused with what is called external snake energy in the literature, which usually applies to energy proportional to the gradient image (see /GAMM and /GRDI).

/EXEN=*wave* Specify a wave that contains energy values that will be added to the snakes energy calculation. The wave must have the same dimensions as *srcWave* and must be single precision float. Each pixel value corresponds to user defined energy which will be multiplied by the /EXEF coefficient and added to the sum which the snake minimizes. Note that when /EXEF is set to zero this component is ignored. An external energy wave may be useful, for example, if you want to attract the snake to the picture boundaries. In that case you can set:

```
Duplicate/O srcWave,extWave
Redimension/S extWave
Variable rows=DimSize(srcWave,0)-1
Variable cols=DimSize(srcWave,1)-1
extWave=(p==0 || q==0 || p==rows || q==cols) ? 0:1
```

/GAMM=*gamma* Sets the coefficient of the energy term corresponding to the gradient. A high value of gamma makes the snake follow lines of high image gradient.

/GRDI=*gWave* Specify the gradient image. This wave must have the same dimensions as *srcWave* and it must be single precision float. The wave corresponds to the quantity `abs(grad(gauss**srcWave))`, where grad is the gradient operator and ** denotes convolution of the source wave with a Gaussian kernel. It is best to run the operation the first time without specifying this wave. When the operation executes, it creates the wave M_GradImage which can then be used in subsequent executions of this operation. If you want to modify the wave to express some other form of energy that you want the operation to minimize, you should use the /EXEN and /EXEF flags.

/ITER=*iterations* Sets the maximum number of iterations. Convergence can be achieved if the value specified by /EPS is met. You can also terminate the process earlier via a user abort (Command-'.' *Macintosh* or Ctrl-Break *Windows*).

/N=*snakePts* Specify the number of vertices in the snake or the number of snake points. Note that if you are providing snake waves in /SX and /SY, you do not need to specify this flag. If you do not specify this flag the default value is 40.

/SIG=*sigma* Sets the size of the Gaussian kernel that is used to convolve the input image when creating the gradient image. Note that you do not need to use this flag if you provide a gradient image. *sigma* is 3 by default. You can use larger odd integers for larger Gaussian kernels which would correspond to a stronger blur.

/STRT={*centerX*, *centerY*, *radius*}
Sets the starting snake to be a circle with the given center and radius. If you use this flag you should also provide the number of snake points using the /N flag.

/STEP=*pixels* Sets the maximum radius of search. By default the radius of the search is 6 pixels and the search follows a clockwise pattern from radius of 1 pixel to maximum radius specified by this flag. Note: the search radius should be smaller than the dimension of a typical feature in the image. If the radius is larger the snake may encompass more

than one object. Larger radius is also less efficient because many of the pixels in that range would result in a snake that crosses itself and hence get rejected in the process.

/SX=*xSnake* Provide an X-wave for the starting snake. You must also provide an appropriate Y-wave using /SY.

/SY=*ySnake* Provide a Y-Wave for the starting snake. Must work in combination with /SX.

/UPDM=*mode* Sets the update mode using any combination of the following:

Value	Update
0	Once when the operation terminates.
1	Once at the end of every iteration.
2	Once after every snake vertex moves.
4	Once for every search position.

/Q Quiet mode; don't print information in the history.

/Z Don't report any errors.

Details

A snake is a two-dimensional, usually closed, path drawn over an image. The snake is described by a pair of XY waves consisting of N vertices (sometimes called "snake elements" or "snaksels"). In this implementation it is assumed that the snake is closed so that the last point in the snake is connected to the first. Snakes are used in image segmentation, when you want to automatically select a contiguous portion of the plane based on some criteria. Unlike the classic contours, snakes do not have to follow a constant level. Their structure (or path) is found by associating the concept of energy with every snake configuration and attempting to find the configuration for which the associated energy is a minimum. The search for a minimum energy configuration is usually time consuming and it strongly depends on the format of the energy function and the initial conditions (as defined by the starting snake). The operation computes the energy as a sum of the following 5 terms:

1. The coefficient alpha times a sum of absolute deviations from the average snake segment length. This term tends to distribute the vertices of the snake at even intervals.
2. The coefficient beta times a sum of energies associated with the curvature of the snake at each vertex.
3. The coefficient gamma times a sum of energies computed from the negative magnitude of the gradient of a Gaussian kernel convolved with the image. This term is usually referred to in the literature as the external energy and usually drives the snake to follow the direction of high image gradients.
4. The coefficient delta times a repulsion energy. Repulsion is computed as an inverse square law by adding contributions from all vertices except the two that are immediately connected to each vertex. This energy term is designed to make sure that the snake does not fold itself into "valleys".
5. The coefficient eta times the sum of values corresponding to the positions of all snake vertices in the wave you provide in /EXEN.

The energy calculation skips all terms for which the coefficient is zero. In addition there is a built-in scan which adds a very high penalty for configurations in which the snake crosses itself.

ImageStats

ImageStats [**/BRXY={*xWave,yWave*}** ***imageWave***

ImageStats [**/M=*val*/P=*planeNumber***]**/R=*roiWave* *imageWave***

ImageStats [**/M=*val*/P=*planeNumber***]**/G={*startP,endP,startQ,endQ*}** ***imageWave***

ImageStats [**/M=*val*/P=*planeNumber***]**/GS={*sMinRow,sMaxRow,sMinCol,sMaxCol*}** ***imageWave***

ImageStats [**/M=*val*/P=*planeNumber***]** ***imageWave***

The ImageStats operation calculates wave statistics for specified regions of interest in a matrix wave. The operation applies to image pixels whose corresponding pixels in the ROI wave are set to zero. It does not print any results in the history area.

Flags

/BEAM Computes the average, minimum, and maximum pixel values in each layer of a 3D wave and 2D ROI. Output is to waves W_ISBeamAvg, W_ISBeamMax, and W_ISBeamMin in the current data folder. Use /RECT to improve efficiency for simple ROI domains. V_ variable results correspond to the last evaluated layer of the 3D wave. Do not use /G, /GS, or /P with this flag. Set /M=1 for maximum efficiency.

/BRXY={*xWave*, *yWave*}

Use this option with a 3D imageWave. It provides a more efficient method for computing average, minimum and maximum values when the set of points of interest is much smaller than the dimensions of an image.

Here *xWave* and *yWave* are 1D waves with the same number of points containing XY integer pixel locations specifying arbitrary pixels for which the statistics are calculated on a plane by plane basis as follows:

$$\text{W\_ISBeamAvg[k]}=\frac{1}{\text{n}}\sum_{i=1}^{n}\text{Im}\,age[xWave[i]][yWave[i]].$$

Pixel locations are zero-based; non-integer entries may produce unpredictable results.

The calculated statistics for each plane are stored in the current data folder in the waves W_ISBeamAvg, W_ISBeamMax and W_ISBeamMin.

Note: This flag is not compatible with any other flag except /BEAM.

/G={*startP*, *endP*, *startQ*, *endQ*}

Specifies the corners of a rectangular ROI. When this flag is used an ROI wave is not required. This flag requires that *startP* ≤ *endP* and *startQ* ≤ *endQ*. When the parameters extend beyond the image area, the command will not execute and V_flag will be set to -1. You should therefore verify that V_flag=0 before using the results of this operation.

/GS={*sMinRow*,*sMaxRow*,*sMinCol*,*sMaxCol*}

Specifies a rectangular region of interest in terms of the scaled image coordinates. Each one of the 4 values will be translated to an integer pixel using truncation.

This flag, /G, and an ROI specification are mutually exclusive.

/M=*val* Calculates the average and locates the minimum and the maximum in the ROI when /M=1. This will save you the computation time associated with the higher order statistical moments.

/P=*planeNumber* Restricts the calculation to a particular layer of a 3D wave. By default, *planeNumber*= -1 and only the first layer of the wave is processed.

/R=*roiWave* Specifies a region of interest (ROI) in the image. The ROI is defined by a wave of type unsigned byte (/b/u), which has the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See **ImageGenerateROIMask** for more information on creating ROI waves.

/RECT={*minRow*, *maxRow*, *minCol*, *maxCol*}

Limits the range of the ROI to a rectangular pixel range with /BEAM. It does not affect complex-valued wave statistics.

Details

The image statistics are returned via the following variables:

`V_adev` Average deviation of pixel values.

`V_avg` Average of pixel values.

`V_kurt` Kurtosis of pixel values.

`V_min` Minimum pixel value.

`V_minColLoc` Specifies the location of the column in which the minimum pixel value was found or the first eligible column if no single column was found.

`V_minRowLoc` Specifies the location of the row in which the minimum pixel value was found or the first eligible row if no single minimum was found.

`V_max` Maximum pixel value.

V_maxColLoc	Specifies the location of the column in which the maximum pixel value was found or the first eligible column if no single column was found.
V_maxRowLoc	Specifies the location of the row in which the maximum pixel value was found or the first eligible row if no single maximum was found.
V_npnts	Number of points in the ROI.
V_rms	Root mean squared of pixel values.
V_sdev	Standard deviation of pixel values.
V_skew	Skewness of pixel values.

Most of these statistical results are similarly defined as for the WaveStats operation. WaveStats will be more convenient to use when calculating statistics for an entire wave.

If *imageWave* is 4D it is often useful to use the reversible conversion

```
Redimension/N=(rows,cols,layers*chunks) ImageWave
```

which allows you to obtain the statistics for each layer and all chunks of the wave. To convert back to 4D, execute:

```
Redimension/N=(rows,cols,layers,chunks) ImageWave
```

See Also

The **ImageGenerateROIMask** and **WaveStats** operations. **ImageStats** on page III-315.

ImageThreshold

ImageThreshold [***flags***] ***imageMatrix***

The ImageThreshold operation converts a grayscale *imageMatrix* into a binary image. The operation supports all data types. However, the source wave must be a 2D matrix. If *imageMatrix* contains NaNs, the pixels corresponding to NaN values are mapped into the value 64. The values for the On and Off pixels are 255 and 0 respectively. The resulting image is stored in the wave M_ImageThresh.

Flags

/C — Calculates the correlation coefficient between the original image and the image generated by the threshold operation. The correlation value is printed to the history window (unless the /Q flag is specified), it is also stored in the variable V_correlation.

/I — Inverts values written to the image, i.e., sets to zero all pixels above threshold.

/M= *method* — Specifies the thresholding method. The calculated value will be printed to the history window (unless /Q is specified) and stored in the variable V_threshold.

- *method*= 1: Automatically calculate a threshold value using an iterative method.
- *method*=2: Image histogram is a simple bimodal distribution.
- *method*=3: Adaptive thresholding. Evaluates threshold based on the last 8 pixels in each row, using alternating rows. Note that this method is not supported when used as part of the operation **ImageEdgeDetection**.
- *method*=4: Fuzzy thresholding using entropy as the measure for "fuzziness".
- *method*=5: Fuzzy thresholding using a method that minimizes a "fuzziness" measure involving the mean gray level in the object and background.

By default *method*=0, in which case you must use the /T flag to specify a manually selected threshold.

/N — Sets the background level to 64 (i.e., NaN).

/O — Overwrites the original image with the calculated threshold image.

If you do not specify the /O flag, the threshold image is written into the wave M_ImageThresh.

/Q — Suppresses printing calculated correlation coefficients (/C) and calculated thresholds (/M) to the history window.

/R=*roiSpec* — Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose values are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can

take any arbitrary shape. See **ImageGenerateROIMask** for more information on creating ROI waves.

In general, the *roiSpec* has the form {*roiWaveName*, *roiFlag*}, where *roiFlag* can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.

roiFlag=1: Set pixels outside the ROI as in original image.

roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default *roiFlag* is set to 1 and it is then possible to use the /R flag using the abbreviated form /R=*roiWave*.

/T=*thresh* Sets the threshold value.

/W= *Twave* Sets the threshold intervals. Each interval is specified by a pair of values in the wave *Twave*. The first element in each pair is the low value and the second element is the high value. Pixel values that lie outside all the specified intervals are set to 0.

References

The automatic thresholding method (/M=1) is described in: T. W. Ridler and S. Calvard, *IEEE Transactions on Systems, Man and Cybernetics*, SMC-8, 630-632, 1978.

See Also

For usage examples see **Threshold Examples** on page III-300. The **ImageGenerateROIMask** and **ImageEdgeDetection** operations.

ImageTransform

ImageTransform [***flags***] ***Method imageMatrix***

The ImageTransform operation performs one of a number of transformations on *imageMatrix*. The result of using most keywords is a new wave stored in the current data folder. Most flags in this operation are exclusive to the keywords in which they are mentioned

Parameters

Method selects type of transform. It is one of the following names:

averageImage Computes an average image for a stack of images contained in 3D *imageMatrix*. The average image is stored in the wave M_AveImage and the standard deviation for each pixel is stored in the wave M_StdvImage in the current data folder. You can use this keyword together with the optional /R flag where a region of interest is defined by zero value points in a ROI wave. The operation sets to NaN the entries in M_AveImage and M_StdvImage that correspond to pixels outside the ROI. *imageMatrix* must have at least three layers.

backProjection Reconstructs the source image from a projection slice and stores the result in the wave M_BackProjection. The projection slice should either be a wave produced by the projectionSlice keyword of this operation or a wave that would be similarly scaled. The input must be a single or double precision real 2D wave. Row scaling must range symmetrically about zero. For example, if the reconstructed image is expected to have 256 rows then the row scaling of the input should be from -128 to 127. Similarly, the column scaling of the input should range between zero and π. An equivalent implementation as a user function is provided in the demo experiment. You can use this implementation as a starting point if you want to develop filtered back projection.

See the projectionSlice keyword and the RadonTransformDemo experiment. For algorithm details see the chapter "Reconstruction of cross-sections and the projection-slice theorem of computerized tomography" in Born and Wolf, 1999.

ccsubdivision Performs a Catmull-Clark recursive generation of B-spline surfaces. There are two valid inputs: triangular meshes or quad meshes.

Quad meshes are assumed to be in the form of a 3D wave where the first plane contains the X-values, the second the Y-values and the third the Z-values.

Triangle meshes are much more complicated to convert into face-edge-vertex arrays so they are less desirable. They are stored in a three column (triplet) wave where the first column corresponds to the X coordinate, the second to the Y coordinate and the third to the Z coordinate. Each triangle is described by three rows in the wave and common

	vertices have to be repeated so that each sequential three rows in the triplet wave correspond to a single triangle. You can also associate a scalar value with each vertex and it will be suitably interpolated as new vertices are computed and old ones are shifted. In this case the input source wave contains one more column in the case of a triplet wave or one more plane in the case of a quad wave. The scalar value is added everywhere as an additional dimension to the spatial part of any point calculation. You can specify the number of iterations using the /I flag. By default the operation executes a single iteration. The output is saved in a quad wave M_CCBSplines that consists of 4 columns. Each row corresponds to a Quad where the 3 planes contain the X, Y, and Z components. If you are using an optional scalar in the input, the scalar result is stored in the wave M_CCBScalar.
cmap2rgb	Converts an image and its associated colormap wave (specified using the /C flag) into an RGB image stored in a 3D wave M_RGBOut.
CMYK2RGB	Converts a CMYK image, stored as 4 layer unsigned byte wave, into a 3 layer, standard RGB image wave. The output wave is M_CMYK2RGB that is stored in the current data folder.
compress	Compresses the data in the *imageWave* using a nonlossy algorithm and stores it in the wave W_Compressed in the current data folder. The compressed wave includes all data associated with *imageWave* including its units and wavenote. Use the decompress keyword to recover the original wave. The operation supports all numeric data types.
convert2gray	Converts an arbitrary 2D wave into an 8-bit normalized 2D wave. The default output wave name is M_Image2Gray.
decompress	Decompresses a compressed wave. It saves a copy of the decompressed wave under the name W_DeCompressed in the current data folder.
extractSurface	Extracts values corresponding to a plane that intersects a 3D volume wave (*imageMatrix*). You must specify the extraction parameters using the /X flag. The volume is defined by the wave scaling of the 3D wave. The result, obtained by trilinear interpolation, is stored in the wave M_ExtractedSurface and is of the type NT_FP64. Points in the plane that lie outside the volume are set to NaN.
fht	Performs a Fast Hartley Transform subject to the /T flag. The source wave must be a 2D real matrix with a power of 2 number of rows and columns. Default output is saved in the double-precision wave M_Hartley in the current data folder. If you use the /O flag the result overwrites *imageMatrix* without changing the numeric type. If *imageMatrix* is single-precision float the conversion is straightforward. All other numeric types are scaled. Single- and double-byte types are scaled to the full dynamic range. 32 bit integers are scaled to the range of the equivalent 16 bit types (i.e., unsigned int is scaled to unsigned short range etc.). It does not support wave scaling or NaN entries.
fillImage	Fills a 2D target image wave with data from a 1D image wave (specified using /D). Both waves must be the same data type, and the number of data points in the target wave must match the number of points in the data wave. There are four fill modes that are specified via the /M flag. The operation supports all noncomplex numeric data types.
findLakes	Originally intended to identify lakes in geographical data, this operation creates a mask for a 2D wave for all the contiguous points whose values are close to each other. You can determine the minimum number of pixels within a contiguous region using the /LARA flag (default is 100). You can determine how close values must be in order to belong to a contiguous region using the /LTOL=*tolerance* flag (default is zero). You can also limit the search region using the /LRCT flag. Use the flag /LTAR=*target* to set the value of the masked regions. By default, the algorithm uses 4-connectivity when looking at adjacent pixels. You can set it to 8-connectivity using the /LCVT flag. The result of the operation is saved in the wave M_LakeFill. It has the same data type as the source wave and contains all the source values outside the masked pixels.
flipCols	Rearrange pixels by exchanging columns symmetrically about a center column or the center of the image (if the number of columns is even). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the /P flag to specify the plane that you want to operate on.
flipRows	Rearrange pixels in the image by exchanging rows symmetrically about the middle row or the middle of the image (if the image has an even number of rows). The exchange is

	performed in place and can be reverted by repeating the operation. When working with 3D waves, use the /P flag to specify the plane that you want to operate on.
flipPlanes	Rearrange data in a 3D wave by exchanging planes symmetrically about the middle plane. The operation is performed in place and can be reverted by repeating the operation.
fuzzyClassify	Segments grayscale and color images using fuzzy logic. Iteration stops when it reaches convergence defined by /TOL or the maximum number of iterations specified by /I. It is a good practice to specify the tolerance and the number of iterations. If the number of classes is small, the operation prints the class values in the history. Use /Q to eliminate printing and increase performance. Use /CLAS to specify the number of classes and optionally use /CLAM to modify the fuzzy probability values. Use /SEG to generate the segmentation image. The classes are stored in the wave W_FuzzyClasses in the current data folder and it will be overwritten if it already exists. When *imageMatrix* is a grayscale image, each class is a single wave entry. When *imageMatrix* is a RGB image, classes are stored consecutively in the wave W_FuzzyClasses. If you request more classes than are present in *imageMatrix*, you will likely find a degeneracy where the space of a data class is spanned by more than one class. It is a good idea to compute the Euclidean distance between every possible pair of classes and eliminate degeneracies when the distance falls below some threshold. Any real data type is allowed but values in the range [0,255] are optimal. You can segment 3D waves of more than 3 layers in which a class will be a vector of dimensionality equal to the number of layers in *imageMatrix*. For examples see Examples/Imaging/fuzzyClassifyDemo.pxp.
getBeam	Extracts a beam from a 3D wave. A "beam" is a 1D array in the Z-direction. If a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension. The number of points in a beam is equal to the number of layers in *imageWave*. Specify the beam with the /Beam={*row*,*column*} flag. It stores the result in the wave W_Beam in the current data folder. W_Beam has the same numeric type as *imageWave*. Use setBeam to set beam values. (See also, **MatrixOp** beam.)
getChunk	Extracts the chunk specified by chunk index /CHIX from *imageMatrix* and stores it in the wave M_Chunk in the current data folder. For example, if *imageMatrix* has the dimensions (10,20,3,10), the resulting M_Chunk has the dimensions (10,20,3). See also setChunk and insertChunk.
getCol	Extracts a 1D wave, named W_ExtractedCol, from any type of 2D or 3D wave. You specify the column using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. *imageMatrix* can be real or complex. (See also putCol keyword, **MatrixOp** col.)
getPlane	Creates a new wave, named M_ImagePlane, that contains data in the plane specified by the /P flag. The new wave is of the same data type as the source wave. You can specify the type of plane using the /PTYP flag. (See also setPlane keyword, **MatrixOp**.)
getRow	Extracts a 1D wave, named W_ExtractedRow, from any type of 2D or 3D wave. You specify the row using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. *imageMatrix* can be real or complex. (See also setRow keyword, **MatrixOp** row.)
Hough	Performs the Hough transform on the input wave. The result is saved to a 2D wave M_Hough in which the rows are the angle domain and the columns are the radial domain. It is assumed that the input wave is binary with background value of 0. See **Hough Transform** on page III-308.
hsl2rgb	Transforms a 3-plane HSL wave into a 3-plane RGB wave. If the source wave for this operation is of any type other than byte or unsigned byte, the HSL values are expected to be between 0 and 65535. For all source wave types the resulting RGB wave is of type unsigned short. The result of the operation is the wave M_HSL2RGB (of type unsigned word), where the RGB values are in the range 0 to 65535.
hslSegment	Creates a binary image of the same dimensions as the source image, in which all pixels that belong to all three of the specified Hue, Saturation, and Lightness ranges are set to 255 and the others to zero. You can specify the HSL ranges using the /H, /S, and /L

flags. Each flag takes as an argument either a pair of values or a wave containing pairs of values. You must specify the /H flag but you can omit the /S and /L flags in which case the default values (corresponding to full range 0 to 1) are used. *imageMatrix* is assumed to be an RGB image.

imageToTexture

Transforms a 2D or 3D image wave into a 1D wave of contiguous pixel components. The transformation is useful for creating an OpenGL texture (for Gizmo) or for saving a color image in a format requiring either RGB or RGBA sequences.

The /O flag does not apply to imageToTexture.

Use the /TEXT flag to specify the type of transformation. *imageMatrix* must be an unsigned byte wave. A 1D unsigned byte wave named W_Texture is created in the current data folder.

W_Texture's wave note is set to a semicolon-separated list of keyword -value pairs that can be parsed using **StringByKey** and **NumberByKey**:

Keyword	Information Following Keyword
WIDTHPIXELS	**DimSize**(imageMatrix,0) or truncated to nearest power of 2 if /TEXT value is odd
HEIGHTPIXELS	**DimSize**(imageMatrix,1) or truncated to nearest power of 2
LAYERS	**DimSize**(imageMatrix,2)
TEXTUREMODE	val parameter from /TEXT flag
SOURCEWAVE	**GetWavesDataFolder**(imageMatrix, 2)

insertChunk

Inserts a chunk (a 3D wave specified by the /D flag) into *imageMatrix* at chunk index specified by the /CHIX flag. The dimensions of the inserted chunk must match the first three dimensions of *imageMatrix*. The wave must also have the same numeric type. The 4th dimension of *imageMatrix* is incremented by 1 to accommodate the new data. See also getChunk and setChunk.

insertImage

Inserts the image specified by the flag /INSI into *imageMatrix* starting at the position specified by the flags /INSX and /INSY. If the *imageMatrix* is a 3D wave then it inserts the image in the layer specified by the /P flag. The inserted image and *imageMatrix* must be the same data type. The inserted data is clipped to the boundaries of *imageMatrix*.

insertXplane

Inserts a 2D wave as a new plane perpendicular to the X-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be cols x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 20x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.

insertYplane

Inserts a 2D wave as a new plane perpendicular to the Y-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.

insertZplane

Inserts a 2D wave as a new plane perpendicular to the Z-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x cols of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x20. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder. This keyword is included for completeness. You can accomplish the same task using InsertPoints.

Invert

Converts pixel values using the formula `newValue=255-oldValue`. Works on waves of any dimension, but only on waves of type unsigned byte. The result is stored in the wave M_Inverted unless specifying the /O flag.

indexWave — Creates a 1D wave W_IndexedValues in the current data folder containing values from *imageMatrix* that are pointed to by the index wave (see /IWAV). Each row in the index wave corresponds to a single value of *imageMatrix*. If any row does not point to a valid index (within the dimensions of *imageMatrix*), the corresponding value is set to zero and the operation returns an error. Indices are zero based integers; the operation does not support interpolation and ignores wave scaling.

JPEGQ — Generates a lossy JPEG-compressed image wave when used together with the /J flag. The compressed image wave is stored in the wave M_JPEGQ and the size of the equivalent image file is stored in the variable V_value.

matchPlanes — Finds pixels that match test conditions in all layers of a 3D wave. It creates a 2D unsigned byte output wave, M_matchPlanes, that is set to the values 0 and 255. A value of 255 indicates that the corresponding pixel has satisfied test conditions in all layers of the wave for which conditions were provided. Otherwise the pixel value is 0.

Test conditions are entered as a 2D wave using the /D flag. The condition wave must be double precision and it must contain the same number of columns as the number of layers in the 3D source wave. A condition for layer j of the source wave is specified by two rows in column j of the condition wave. The first row entry, say *A*, and the second row entry, say *B*, imply a condition on pixels in layer *j* such that $A \le x < B$. You can have more than one condition for a given layer by adding pairs of rows to the condition wave. For example, if you add in consecutive rows the values *C* and *D*, this implies the test:

$$\left(A \le x \le B\right) \| \left(C \le x \le D\right).$$

If you do not have any conditions for some layer, set its corresponding condition column to NaN. Similarly, if you have two conditions for the first layer and one condition for the second layer, pad the bottom of column 1 in the condition wave with NaNs. See Examples for use of this keyword to perform hue/saturation segmentation.

offsetImage — Shifts an image in the XY plane by dx, dy pixels (specified by the /IOFF flag). Pixels outside the shifted image will be set to the specified background value. The operation works on 2D waves or on 3D waves with the optional /P flag. When shifting a 3D wave with no specified plane, it creates a 3D wave with all planes offset by the same amount. The wave M_OffsetImage contains the result in the current data folder.

The /O flag is not supported with offsetImage.

padImage — Resizes the source image. When enlarged, values from the last row and column fill in the new area. The /N flag specifies the new image size in terms of the rows and columns change. The /W flag specifies whether data should be wrapped when padding the image. Unless you use the /O flag, the result is stored in the wave M_PaddedImage in the current data folder.

projectionSlice — Computes a projection slice for a parallel fan of rays going through the image at various angles. For every ray in the fan the operation computes a line integral through the image (equivalent to the sum of the line profile along the ray). The operation computes the line integrals for multiple fans defined by the number and position of the rays as well as the angle that they make with the positive X-direction. Use the /PSL flag to specify the projection parameters. The projection slice itself is stored in a 2D wave M_ProjectionSlice where the rows correspond to the rays and the columns correspond to the selected range of angles. The operation does not support wave scaling. If the source wave is 3D the projection slice currently supports slices that are perpendicular to the z-axis and specified by their plane number.

See the backProjection keyword and the RadonTransformDemo experiment. For algorithm details see the chapter "Reconstruction of cross-sections and the projection-slice theorem of computerized tomography" in Born and Wolf, 1999.

putCol — Sets a column of *imageMatrix* to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number. See also getCol keyword.

putRow — Sets a row of *imageMatrix* to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is

a mismatch in the number of entries between the specified waves, the operation uses the smaller number. See also getRow keyword.

rgb2cmap — Computes a default color map of 256 colors to represent the input RGB image. The colors are computed by clustering the input pixels in RGB space. The resulting color map is stored in the wave M_ColorIndex in the current data folder. The operation also saves the wave M_IndexImage which contains an index into the colormap that can be used to display the image using the commands:

```
NewImage M_IndexImage
ModifyImage M_IndexImage cindex= M_ColorIndex
```

To change the default number of colors use the /NCLR flag. When the number of colors are greater than 256, M_IndexImage will be a 16-bit unsigned integer or a 32 bit integer wave depending on the number. rgb2cmap supports input images in the form of 3D waves of type unsigned byte or single precision float. The floating point option may be used to input images in colorspaces that use signed numeric data.

rgb2gray — When the input *imageMatrix* is a 3D RGB wave, rgb2gray produces a 2D wave of type unsigned byte containing the grayscale representation of the input. By default, the operation stores the output in the wave M_RGB2Gray in the current data folder. The RGB values are converted into the luminance Y of the YIQ standard using:

```
Y = 0.299R + 0.587G + 0.114B
```

When the input imageMatrix is a 4D wave containing multiple (3 layer) RGB chunks, the conversion produces a 3D wave where each layer corresponds to the grayscale conversion of the corresponding chunk in the input wave. In this case the numeric type of the output is the same as that of the input but the conversion formula is the same. The /O flag is not supported when transforming a 4D RGB wave.

rgb2hsl — Converts an RGB image stored in a 3D wave into another 3D wave in which the three planes correspond to Hue, Saturation and Lightness in the HSL color model. Values of all components are normalized to the range 0 to 255 unless the /U flag is used or if the source wave is not 8-bit, in which case the range is 0 to 65535. The default output wave name is M_RGB2HSL.

rgb2i123 — Performs a colorspace conversion of an RGB image into the following quantities:

$$I_1 = |R-G|D$$
$$I_2 = |R-B|D \quad \text{where} \quad D = \frac{255}{|R-G|+|R-B|+|G-B|}.$$
$$I_3 = |G-B|D,$$

*I*1, *I*2, and *I*3 are stored in the wave M_I123 (using the same data type as the original RGB wave) in the current data folder. *I*1 is stored in the first layer, *I*2 in the second and *I*3 in the third. This color transformation is said to have useful applications in machine vision.

For more information see: Gevers and Smeulders (1999).

removeXplane — Removes one or more planes perpendicular to the X-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.

removeYplane — Removes one or more planes perpendicular to the Y-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.

removeZplane — Removes one or more planes perpendicular to the Z-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.

rgb2xyz — converts a 3D RGB image wave into a 3D wave containing the XYZ color space equivalent. The conversion is based on the D65 white point and uses the following transformation:

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 0.412453 & 0.357580 & 0.180423 \\ 0.212671 & 0.715160 & 0.072169 \\ 0.019334 & 0.119193 & 0.950227 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix}$$

The XYZ values are stored in a wave named "M_RGB2XYZ" unless the /O flag is used, in which case the source image is overwritten and converted into single precision wave (NT_FP32).

roiTo1D

Copies all pixels in an ROI and saves them sequentially in a 1D wave. The ROI is specified by /R. The ROI wave must have the same dimensions as *imageMatrix*. If *imageMatrix* is a 3D wave, the ROI must have as many layers as *imageMatrix*. The wave W_roi_to_1d contains the output in the current data folder, has the same numeric type as *imageMatrix*, and contains the selected pixels in a column-major order.

rotateCols

Rotates rows in place. This operation is analogous to the **Rotate** operation except that it works on images and rotates an integer number of rows. The number of rows is specified by the /G flag.

When *imageMatrix* contains multiple layers you can use the /P flag to specify the layer of the wave that will undergo rotation. By default, if you do not specify the /P flag and if *imageMatrix* consists of three layers (RGB), then all three layers are rotated. Otherwise the operation rotates only the first layer of the wave.

rotateRows

Rotates columns in place. This operation is analogous to the **Rotate** operation except that it works on images and rotates an integer number of columns. The number of columns is specified by the /G flag.

When *imageMatrix* contains multiple layers you can use the /P flag to specify the layer of the wave that will undergo rotation. By default, if you do not specify the /P flag and if *imageMatrix* consists of three layers (RGB), then all three layers are rotated. Otherwise the operation rotates only the first layer of the wave.

scalePlanes

Scales each plane of the 3D wave, *imageMatrix*, by a constant taken from the corresponding entry in the 1D wave specified by the /D flag. The result is stored in the wave M_ScaledPlanes unless the /O flag is specified, in which case scaling is done in place.

When using /O, first redimension the wave to a different data type to make sure there are no artifacts due to type clipping.

If *imageMatrix* is double precision, M_ScaledPlanes is double precision. Otherwise M_ScaledPlanes is single precision.

This operation also supports the optional flag.

Note that when you display M_ScaledPlanes, which has three planes that originated from scaling byte data, you will have to multiply the wave by 255 to see the image because the RGB format for single and double precision data requires values in the range 0 to 65535.

selectColor

Creates a mask for the image in which pixel values depend on the proximity of the color of the image to a given central color. The central color, the tolerance and a grayscale indicator must be specified using the /E flag.

For example, `/E={174,187,75,10,1}` specifies an RGB of (174,187,75), a tolerance level of 10 and a requested grayscale output.

RGB values must be provided in a range appropriate for the source image. If the source wave type is not byte or unsigned byte, then the range of the RGB components should be 0 to 65535.

The color proximity is calculated in the nonuniform RGB space and the tolerance applies to the maximum component difference from the corresponding component of the central color.

The tolerance, just like the central color, should be appropriate to the type of the source wave.

The generated mask is stored in the wave M_SelectColor in the current data folder. If a wave by that name exists prior to the execution of this operation, it is overwritten.

	You can also use the /R flag with this operation to limit the color selection to pixels in the ROI wave whose value is zero.
setBeam	Sets the data of a particular beam in *imageMatrix*. A "beam" is a 1D array in the Z-direction. If a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension. Specify the beam with the /Beam={*row*,*column*} flag and the 1D beam data wave with the /D flag. The beam data wave must have the same number of elements as the number of layers and same numeric type as *imageMatrix*. Use getBeam to extract the beam.
setChunk	Overwrites the data in the wave *imageMatrix* at chunk index specified by /CHIX with the data contained in a 3D wave specified by the /D flag. The assigned data must be contained in a wave that matches the first three dimensions of *imageMatrix* and must have the same number type. See also getChunk and insertChunk.
setPlane	Sets a plane (given by the /P flag) in the designated image with the data in a wave specified by the /D flag. It is designed as a complement of the getPlane keyword to provide an easier (faster) way to create multiplane images. Note that the operation supports setting a plane when the source data is smaller than the destination plane in which case the source data is placed in memory contiguously starting from the corner pixel of the destination plane. If the source data is larger than the destination plane it is clipped to the appropriate rows and columns. If you are setting all planes in the destination wave using algorithmically named source waves you could use the stackImages keyword instead. See also getPlane keyword.
shading	Calculates relative reflectance of a surface for a light source position defined by the /A flag. The operation estimates the slope of the surface and then computes a relative reflectance defined as the dot product of the direction of the light and the normal to the surface at the point of interest. Reflectivity is scaled using the expression: *outPixel* = *shadingA* * (*sunDirection* · *surfaceNormal*) + *shadingB* By default *shadingA*=1, *shadingB*=0. The result is stored in the wave M_ShadedImage, which has the same data type as the source wave. If the source wave is any integer type, and the value of *shadingA*=1 the operation sets that value to 255. The smallest supported wave size is 4x4 elements. Values along the boundary (1 pixel wide) are arbitrary because there are no derivatives calculable for those pixels, so these pixels are filled with duplicates of the inner rows and columns.
shrinkRect	Shrinks *imageMatrix* to include only the minimum rectangle that contains all the pixels whose value is different from an outer value. The outer value is specified with the /F flag. This is useful in situations where **ImageSeedFill** has set the pixels around the object of interest to some outer value and it is desired to extract the smallest rectangle that contains interesting data. The output is stored in the wave M_Shrunk.
stackImages	Creates a 3D or 4D stack from individual image waves in the current data folder. The waves should be of the form *baseNameN*, where *N* is a numeric suffix specifying the sequence order. *imageMatrix* should be the name of the first wave that you want to add to the stack. You can use the /NP flag to specify the number of waves that you want to add to the stack The result is a 3D or 4D wave named M_Stack, which overwrites any existing wave of that name in the current data folder. With /K, it kills all waves copied into the stack.
sumAllCols	Creates a wave W_sumCols in which every entry is the sum of the pixels on the corresponding image column. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.
sumAllRows	Creates a wave W_sumRows in which every entry is the sum of the pixels on the corresponding image row. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.

sumCol — Stores in the variable V_value the sum of the elements in the column specified by /G flag and optionally the /P flag.

sumPlane — Stores in the variable V_value the sum of the elements in the plane specified by the /P flag.

sumPlanes — Creates a 2D wave M_SumPlanes which contains the same number of rows and columns as the 3D source wave. Each entry in M_SumPlanes is the sum of the corresponding pixels in all the planes of the source wave. M_SumPlanes is a double precision wave if the source wave is double precision. Otherwise it is a single precision wave.

sumRow — Stores in the variable V_value the sum of the elements of a row specified by /G flag and optionally the /P flag.

swap — Swaps image data following a 2D FFT. The transform swaps diagonal quadrants of the image in one or more planes. This keyword does not support any flags. The swapping is done in place and it overwrites the source wave.

swap3D — Swaps data following a 3D FFT. The transform swaps diagonal quadrants of the data. This keyword does not support any flags. The swapping is done in place and the source wave is overwritten.

transposeVol — Transposes a 3D wave. The transposed wave is stored in M_VolumeTranspose. The /O flag does not apply. The operation supports the following 5 transpose modes which are specified using the /G flag:

mode	**Equivalent Command**
1	`M_VolumeTranspose=`*`imageMatrix`*`[p][r][q]`
2	`M_VolumeTranspose=`*`imageMatrix`*`[r][p][q]`
3	`M_VolumeTranspose=`*`imageMatrix`*`[r][q][p]`
4	`M_VolumeTranspose=`*`imageMatrix`*`[q][r][p]`
5	`M_VolumeTranspose=`*`imageMatrix`*`[q][p][r]`

vol2surf — Creates a quad-wave output (appropriate for display in Gizmo) that wraps around 3D "particles". A particle is defined as a region of nonzero value voxels in a 3D wave. The algorithm effectively computes a box at the resolution of the input wave which completely encloses the data. The output wave M_Boxy is a 2D single precision wave of 12 columns where each row corresponds to one disjoint quad and the columns provide the sequential X, Y, and Z coordinates of the quad vertices.

voronoi — Computes the voronoi tesselation of a convex domain defined by the X, Y positions of the input wave. *imageMatrix* must be a triplet wave where the first column contains the X-values, the second column contains the Y-values and the third column is an arbitrary (zero is recommended) constant. The result of the operation is stored in the two column wave M_VoronoiEdges which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle which contains the convex domain.

xProjection — Computes the projection in the X-direction and stores the result in the wave M_xProjection. See zProjection for more information.

xyz2rgb — Converts a 3D single precision XYZ color-space data into RGB based on the D65 white point. The transformation used is:

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} 3.240479 & -1.537150 & -0.498535 \\ -0.969256 & 1.875992 & 0.041556 \\ 0.055648 & -0.204043 & 1.057311 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}.$$

If you do not specify the /O flag, the results are saved in a single precision 3D wave (NT_FP32) "M_XYZ2RGB".

Note that not all XYZ values map into positive RGB triplets (consider colors that reside outside the RGB triangle in the XYZ diagram). This operation gives you the following choices: by default, the output wave is a single precision wave that will include

possible negative RGB values. If you specify the /U flag, for unsigned short output wave, the operation will set to zero all negative components and scale the remaining ones in the range 0 to 65535.

yProjection — Computes the projection in the Y-direction and stores the result in the wave M_yProjection. See zProjection for more information.

zDot — Computes the dot product of a beam in *srcWave* with a 1D zVector wave (specified with the /D flag). This will convert stacked images of spectral scans into RGB or XYZ depending on the scaling in zVector. The *srcWave* and zVector must be the same data type (float or double). The wave M_StackDot contains the result in the current data folder.

zProjection — Computes the projection in the Z-direction and stores the result in the wave M_zProjection. The source wave must be a 3D wave of arbitrary data type. The value of the projection depends on the method specified via the /METH flag.

Flags

/A={*azimuth*, *elevation* [, *shadingA*, *shadingB*]}

Specifies parameters for shade. Position of the light source is given by *azimuth* (measured in degrees counter-clockwise) and *elevation* (measured in degrees above the horizon).

The parameters *shadingA* and *shadingB* are optional. By default their values are 1 and 0, respectively.

/Beam={*row*,*column*}

Designates a beam in a 3D wave; both *row* and *column* are zero based.

/BPJ={*width*,*height*} Specifies the backProjection parameters: *width* and *height* are the width and height of the reconstructed image and should be equal to the size of the original wave.

/C=*CMapWave* Specifies the colormap wave for cmap2rgb keyword. The *CMapWave* is expected to be a 2D wave consisting of three columns corresponding to the RGB entries.

/CHIX=*chunkIndex* Identifies the chunk index for getting, inserting or setting a chunk of data in a 4D wave. *chunkIndex* ranges from 0 to the number of chunks in *imageMatrix*.

/CLAM=*fuzzy* Sets the value used to compute the fuzzy probability in fuzzyClassify. It must satisfy *fuzzy* > 1 (default is 2).

/CLAS=*num* Sets the number of requested classes in fuzzyClassify. If you don't know the number of expected classes and *num* is too high, fuzzyClassify will likely produce some degenerate classes.

/D=*waveName* Specifies a data wave. Check the appropriate keyword documentation for more information about this wave.

/F=*value* Increases the sampling in the angle domain when used with the Hough keyword. By default *value*=1 and the operation results in single degree increments in the interval 0 to 180, and if *value*=1.5 there will be 180*1.5 rows in the transform.

Specifies the outer pixel value surrounding the region of interest when used with shrinkRect keyword.

/G=*colNumber* Specifies either the row or column number used in connection with getRow or getCol keywords. This flag also specifies the transpose *mode* with the transposeVol keyword.

/H={*minHue*, *maxHue*}

/H=*hueWave* Specifies the range of hue values for selecting pixels. The hue values are specified in degrees in the range 0 to 360. Hue intervals that contain the zero point should be specified with the higher value first, e.g., `/H={330,10}`.

Use *hueWave* when you have more than one pair of hue values that bracket the pixels that you want to select.

See **HSL Segmentation** on page III-318 for an example.

/I=*iterations* Sets the number of iterations in ccsubdivision and in fuzzyClassify.

/INSI=*imageWave* Specifies the wave, *imageWave*, to be used with the insertImage keyword. *imageWave* is a 2D wave of the same numeric data type as *imageMatrix*.

/INSW=*wave* Specifies the 2D wave to be inserted into a 3D wave using the keywords: insertXplane, insertYplane, or insertZplane.

/INSX=*xPos* Specifies the pixel position at which the first row is inserted. Ignores wave scaling.

/INSY=*yPos* Specifies the pixel position at which the first column is inserted. Ignores wave scaling.

/IOFF={*dx*,*dy*,*bgValue*}
Specifies the amount of positive or negative integer offset with *dx* and *dy* and the new background value, *bgValue*, with the offsetImage keyword.

/IWAV=*wave* Specifies the wave which provides the indices when used with the keyword indexWave. The wave should have as many columns as the dimensions of *imageMatrix* (2, 3, or 4). For example, to specify indices for pixels in an image, the wave should have two columns. The first column corresponds to the row designation and the second to the column designation of the pixel. The wave can be of any number type (other than complex) and entries are assumed to be integer indices; there is no support for interpolation or for wave scaling.

/J=*quality* Specifies the quality of JPEG image compression. *quality* can have values ranging from 0 (lowest) to 100 (highest). This flag is used with the JPEGQ keyword.

/L={*minLight, maxLight*}
/L=*lightnessWave* Specifies the range of lightness for selecting pixels. The lightness values are in the range 0-1. If you do not use the /L flag than the default full range is used.

Use *lightnessWave* when you have more than one pair of lightness values corresponding to the pixels that you want to select. For each pair, values should be arranged so that the smaller one is first and the larger is second. There is no restriction on the order of pairs in the wave except that they match the other waves used by the operation.

/LARA=*minPixels*
Specifies the minimum number of pixels required for an area to be masked by the findLakes keyword. If you do not specify this flag, the default value used is 100.

/LCVT use 8-connectivity instead of 4-connectivity.

/LRCT={*minX*,*minY*,*maxX*,*maxY*}
Sets the rectangular region of interest for the findLakes keyword. The operation will not affect the original data outside the specified rectangle. The X and Y values are the scaled values (i.e., using wave scaling).

/LTAR=*target* Set the target value for the masked region in the findLakes keyword.

/LTOL=*tol* Specifies the tolerance for the findLakes keyword. By default the tolerance is zero. The tolerance must be a positive number. The operation uses the tolerance by requiring neighboring pixels to have a value between that of the current pixel V and V+*tol*.

/M=*n* Specifies the method by which a 2D target image is filled with data from a 1D wave using the fillImage keyword.

n =0: Straight column fill, which you can also accomplish by a redimension operation.

n =1: Straight row fill.

n =2: Serpentine column fill. The points from the data wave are sequentially loaded onto the first column and continue from the last to the first point of the second column, and then sequentially through the third column, etc.

n =3: Serpentine row fill.

/METH=*method* Determines the values of the projected pixels for xProjection, yProjection, and zProjection keywords.

method =1: Pixel (i,j) in M_zProjection is assigned the maximum value that (i,j,*) takes among all layers of *imageMatrix* (default).

method =2: Pixel (i,j) in M_zProjection is assigned the average value that (i,j,*) takes among all layers of *imageMatrix*.

method =3: Pixel (i,j) in M_zProjection is assigned the minimum value that (i,j,*) takes among all layers of *imageMatrix*.

/N={*rowsToAdd, colsToAdd*}
Creates an image that is larger or smaller by *rowsToAdd*, *colsToAdd*. The additional pixels are set by duplicating the values in the last row and the last column of the source image.

/NCLR=*M* Specifies the maximum number of colors to find with the rgb2cmap keyword. *M* must be a positive number; the default value is 256 colors.

The result of the operation is saved in the wave M_paddedImage.

/NP=*numPlanes* Specifies the number of planes to remove from a 3D wave when using the removeXplane, removeYplane, or removeZplane keywords. Specifies the number of waves to be added to the stack with the stackImages keyword.

/O Overwrites the input wave with the result except in the cases of Hough transform and cmap2rgb. Does not apply to the transposeVol parameter.

/P=*planeNum* Specifies the plane on which you want to operate with the rgb2gray or getPlane keywords. Also used for getRow or getCol if the source wave is 3D.

/PSL={*xStart*,*dx*,*Nx*,*aStart*,*da*,*Na*}
Specifies projection slice parameters. *xStart* is the first offset of the parallel rays measured from the center of the image. *dx* is the directed offset to the next ray in the fan and *Nx* is the number of rays in the fan. *aStart* is the first angle for which the projection is calculated. The angle is measured between the positive X-direction and the direction of the ray. *da* is the offset to the next angle at which the fan of rays is rotated and *Na* is the total number of angles for which the projection is computed.

/PTYP=*num* Specifies the plane to use with the getPlane keyword.

num=0: XY plane.

num=1: XZ plane.

num=2: YZ plane.

/Q Quiet flag. When used with the Hough transform, it suppresses report to the history of the angle corresponding to the maximum.

/R=*roiWave* Specifies a region of interest (ROI) defined by *roiWave*. For use with the keywords: averageImage, scalePlanes and selectColor.

/S={*minSat, maxSat*}
/S=*saturationWave* Specifies the range of saturation values for selecting pixels. The saturation values are in the range 0 to 1. If you do not use the /S flag, the default value is the full saturation range.

Use *saturationWave* when you have more than one pair of saturation values. If you use a saturation wave you must also use a lightness wave (see /L). *saturationWave* should consist of pairs of values where the first point is the lower saturation value and the second point is the higher saturation value. There is no restriction on the order of pairs within the wave.

/SEG Computes the segmentation image for fuzzyClassify. The image is stored in the 2D wave M_FuzzySegments. The value of each pixel is 255**classIndex*/*number of classes*. Here *classIndex* is the index of the class to which the pixel belongs with the highest probability.

/T=*flag* Use one or more of the following flags.

1: Swaps the data so that the DC is at the center of the image.

2: Calculates the power defined as: $P(f) = 0.5 \cdot (H(f)^2 + H(-f)^2)$.

/TEXT=*val* Specifies the type of texture to create with the imageToTexture keyword. *val* is a binary flag that can be a combination of the following values.

val	Texture
1	Truncates each dimension to the nearest power of 2, which is required for OpenGL textures.
2	Creates a 1D texture (all other textures are for 2D applications).
4	Creates a single channel texture suitable for alpha or luminance channels.
8	Creates a RGB texture from a 3 (or more) layer data.
16	Creates a RGBA texture. If *imageMatrix* does not have a 4th layer, alpha is set to 255.

/TOL=*tolerance* Sets the tolerance for iteration convergence with fuzzyClassify. Convergence is satisfied when the sum of the squared differences of all classes drops below *tolerance*, which must not be negative.

/U Creates an HSL wave of type unsigned short that contains values between 0 and 65535 when used with rgb2hsl.

/W Pads the image by wrapping the data. If you are adding more rows or more columns than are available in the source wave, the operation cycles through the source data as many times as necessary.

/X={*Nx,Ny,x1,y1,z1,x2,y2,z2,x3,y3,z3*}
Nx and *Ny* are the rows and columns of the wave M_ExtractedSurface. The remaining parameters specify three 3D points on the extracted plane. The three points must be chosen at the vertices of the plane and entered in clock-wise order without skipping a vertex.

/Z Ignores errors.

Examples

If you want to insert a 2D (M x N) wave, plane0, into plane number 0 of an (M x N x 3) wave, rgbWave:

```
ImageTransform /P=0/D=plane0 setPlane rgbWave
```

If your source wave is 100 rows by 100 columns and you want to create a montage of this image use:

```
ImageTransform /W/N={200,200} padImage srcWaveName
```

An example of hue and saturation segmentation on an HSL wave.

```
Function hueSatSegment(hslW,lowH,highH,lowS,highS)
    Wave hslW
    Variable lowH,highH,lowS,highS

    Make/D/O/N=(2,3) conditionW
    conditionW={{lowH,highH},{lowS,highS},{NaN,NaN}}
    ImageTransform/D=conditionW matchPlanes hslW
    KillWaves/Z conditionW
End
```

An example of voronoi tesselation.

```
Make/O/N=(33,3) ddd=gnoise(4)
ImageTransform voronoi ddd
Display ddd[][1] vs ddd[][0]
ModifyGraph mode=3,marker=19,msize=1,rgb=(0,0,65535)
Appendtograph M_VoronoiEdges[][1] vs M_VoronoiEdges[][0]
SetAxis left -15,15
SetAxis bottom -5,10
```

ImageUnwrapPhase

ImageUnwrapPhase [***flags***][**qualityWave=*qWave*,**] **srcwave=*waveName***

The ImageUnwrapPhase operation unwraps the 2D phase in srcWave and stores the result in the wave M_UnwrappedPhase in the current data folder. srcWave must be a real valued wave of single or double precision. Phase is measured in cycles (units of 2π).

Parameters

qualityWave=*qWave* Specifies a wave, *qWave,* containing numbers that rate the quality of the phase stored in the pixels. *qWave* is 2D wave of the same dimensions as srcWave that can be any real data type and values can have an arbitrary scale. If used with /M=1 the quality values determine the order of phase unwrapping subject to branch cuts, with higher quality unwrapped first. If used with /M=2 the unwrapping is guided by the quality values only. This wave must not contain any NaNs or INFs.

srcwave=*waveName* Specifies a real-valued SP or DP wave that may contain NaNs or INFs but is otherwise assumed to contain the phase modulo 1.

Flags

/E — Eliminate dipoles. Only applies to Goldstein's method (/M=1). Dipoles are a pair of a positive and negative residues that are side by side. They are eliminated from the unwrapping process by replacing them with a branch cut. The variable V_numResidues contains the number of residues remaining after removal of the dipoles.

/L — Saves the lookup table(LUT) used in the analysis with /M=1. This information may be useful in analyzing your results. The LUT is saved as a 2D unsigned byte wave M_PhaseLUT in the current data folder. Each entry consists of 8-bit fields:

bit 0: Positive residue.

bit 1: Negative residue.

bit 2: Branch cut.

bit 3: Image boundary exclusion.

Other bits are reserved and subject to change. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

/M=*method* — Determines the method for computing the unwrapped phase:

method=0: Modified Itoh's algorithm, which assumes that there are no residues in the phase. The phase is unwrapped in a contiguous way subject only to the ROI or singularities in the data (e.g., NaNs or INFs). You will get wrong results for the unwrapped phase if you use this method and your data contains residues.

method=1: Modified Goldstein's algorithm. Creates the variables V_numResidues and V_numRegions. Optional *qWave* can determine order of unwrapping around the branch cuts.

method=2: Uses a quality map to decide the unwrapping path priority. The quality map is a 2D wave that has the same dimensions as the source wave but could have an arbitrary data type. The phase is unwrapped starting from the largest value in the quality map.

/MAX=*len* — Specifies the maximum length of a branch cut. Only applicable to Goldstein's method (/M=1). By default this is set to the largest of rows or columns.

/Q — Suppresses messages to the history.

/R=*roiWave* — Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u) that has the same number of rows and columns as *waveName*. The ROI itself is defined by entries or pixels in the *roiWave* with value of 1. Pixels outside the ROI should be set to zero. The ROI does not have to be contiguous but it is best if you choose a convex ROI in order to make sure that any branch cuts computed by the algorithm lie completely inside the ROI domain.

/REST = *threshold* — Sets the threshold value for evaluating a residue. The residue is evaluated by the equivalent of a closed path integral. If the path integral value exceeds the threshold value, the top-left corner of the quad is taken to be a positive residue. If the path integral is less than -*threshold*, it is a negative residue.

Details

Phase unwrapping in two dimensions is difficult because the result of the operation needs to be such that any path integral over a closed contour will vanish. In many practical situations, certain points in the plane have the property that a path integral around them is not zero. These nonzero points are residues. We use the definition that when a counterclockwise path integral leads to a positive value the residue is called a positive residue.

ImageUnwrapPhase uses the modified Itoh's method by default. Phase is unwrapped with an offset equal to the first element that is allowed by the ROI starting at (0,0) and scanning by rows. If there are no residues or if you unwrap the phase using Itoh's algorithm, then the phase is unwrapped only subject to the optional ROI using a seed-fill type algorithm that unwraps by growing a region outward from the seed pixel. Each time that the region growing is terminated by boundaries (external or due to the ROI), the algorithm returns to the row scanning to find a new starting point.

If there are residues and you choose Goldstein's method, the residues are first mapped into a lookup table (LUT) and branch-cuts are determined between residues and boundaries. It is also possible to remove some residues (dipoles) using the /E flag. Phase is then unwrapped in regions bounded by branch cuts using a seed-fill type algorithm that does not cross branch cuts. With a quality wave, the algorithm follows the same

seed-fill approach except that it gives priority to pixels with high quality level. The phase on the branch cuts themselves is subsequently calculated.

The output wave M_UnwrappedPhase has the same wave scaling and dimension units as srcWave. The unwrapped phase is units of cycles; you will have to multiply it by 2π if you need the results in radians.

The operation creates two variables:

V_numResidues	Number of residues encountered(if using /M=1).
V_numRegions	Number of independent phase regions. In Goldstein's method the regions are bounded by branch cuts, but in Itoh's method they depend on the content of the ROI wave.

Examples

To unwrap a complex wave wCmplx:

```
Make/O/N=(DimSize(wCmplx,0),DimSize(wCmplx,1) phaseWave
phaseWave=atan2(imag(wCmplx),real(wCmplx))/2*pi
ImageUnwrapPhase/N=1 srcWave=phaseWave
```

To find the locations of positive residues in the phase:

```
ImageUnwrapPhase/N=1/L srcWave=phaseWave
Duplicate/O M_PhaseLUT ee
ee=M_PhaseLUT&3 ? 1:0
```

To find the branch cuts:

```
Duplicate/O M_PhaseLUT bc
bc=M_PhaseLUT&4 ? 1:0
```

ImageWindow

ImageWindow [**/I/O/P=*param***] ***method srcWave***

The ImageWindow operation multiplies the named waves by the specified windowing method.

ImageWindow is useful in preparing an image for FFT analysis by reducing FFT artifacts produced at the image boundaries.

Parameters

srcWave Two-dimensional wave of any numerical type. See **WindowFunction** for windowing one-dimensional data.

method Selects the type of windowing filter, which is one of the following:

Hanning: $w(n) = \frac{1}{2}\left[1 - \cos\left(\frac{2\pi n}{L-1}\right)\right] \qquad 0 \le n \le L-1$.

Hamming: $w(n) = 0.54 - 0.46\cos\left(\frac{2\pi n}{L-1}\right) \qquad 0 \le n \le L-1$.

Bartlet: Synonym for Bartlett.

Bartlett: $w(n) = \begin{cases} \frac{2n}{L-1} & 0 \le n \le \frac{L-1}{2} \\ 2 - \frac{2n}{L-1} & \frac{L-1}{2} \le n \le L-1 \end{cases}$.

Blackman: $w(n) = 0.42 - 0.5\cos\left(\frac{2\pi n}{L-1}\right) + 0.08\cos\left(\frac{4\pi n}{L-1}\right) \qquad 0 \le n \le L-1$.

Kaiser: $$\frac{I_0\left\{\omega_a\left[((L-1)/2)^2-[n-((L-1)/2)]^2\right]^{1/2}\right\}}{I_0\{\omega_a((L-1)/2)\}} \qquad 0 \le n \le L-1 .$$

where $I_0\{\ldots\}$ is the zeroth-order Bessel function of the first kind and ω_a is the design parameter specified by /P=*param*.

KaiserBessel20: $\alpha = 2.$

KaiserBessel25: $\alpha = 2.5.$

KaiserBessel30: $\alpha = 3.$

$$w(n) = \frac{I_0\left(\pi\alpha\sqrt{1-\left(\frac{n}{(L)/2}\right)^2}\right)}{I_0(\pi\alpha)} \qquad 0 \le |n| \le \frac{L}{2} .$$

$$I_0(X) = \sum_{k=0}^{\infty}\left(\frac{(x/2)^2}{k!}\right)^2$$

In all equations, L is the array width and n is the pixel number.

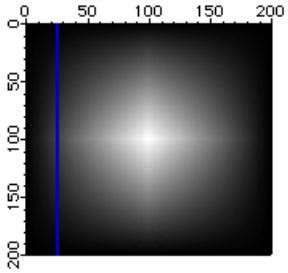
Flags

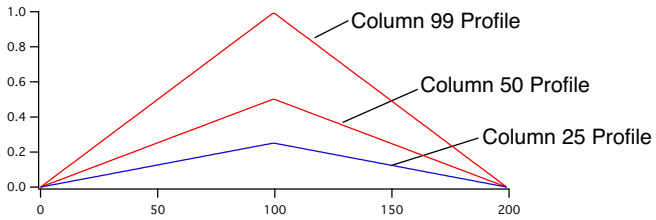
/I	Creates only the output wave containing the windowing filter values that are used to multiply each pixel in *srcWave*. It does not filter the source image.
/O	Overwrites the source image with the output image. If /O is not used then the operation creates the M_WindowedImage wave containing the filtered source image.
/P=*param*	Specifies the design parameter for the Kaiser window.

Details

The 1-dimensional window for each column is multiplied by the value of the corresponding row's window value. In other words, each point is multiplied by the both the row-oriented and column-oriented window value.

This means that all four edges of the image are decreased while the center remains at or near its original value. For example, applying the Bartlett window to an image whose values are all equal results in a trapezoidal pyramid of values:





The default output wave is created with the same data type as the source image. Therefore, if the source image is of type unsigned byte (/b/u) the result of using /I will be identically zero (except possibly for the middle-most pixel). If you keep in mind that you need to convert the source image to a wave type of single or double precision in order to perform the FFT, it is best if you convert your source image (e.g., `Redimension/S srcImage`) before using the ImageWindow operation.

The windowed output is in the M_WindowedImage wave unless the source is overwritten using the /O flag.

The necessary normalization value (equals to the average squared window factor) is stored in V_value.

Examples

To see what one of the windowing filters looks like:

```
Make/N=(80,80) wShape                  // Make a matrix
ImageWindow/I/O Blackman wShape        // Replace with windowing filter
Display;AppendImage wShape                  // Display windowing filter
Make/N=2 xTrace={0,79},yTrace={39,39}       // Prepare for 1D section
AppendToGraph yTrace vs xTrace
ImageLineProfile srcWave=wShape, xWave=xTrace, yWave=yTrace
Display W_ImageLineProfile             // Display 1D section of filter
```

IndependentModule

```
#pragma IndependentModule = imName
```

The IndependentModule pragma designates groups of one or more procedure files that are compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows functioning control panels and menus to continue to work regardless of user programming errors.

See Also

Independent Modules on page IV-214, **The IndependentModule Pragma** on page IV-43 and **#pragma**.

IndependentModuleList

```
IndependentModuleList(listSepStr)
```

The IndependentModuleList function returns a string containing a list of independent module names separated by listSepStr.

Use **StringFromList** to access individual names.

Parameters

listSepStr contains the character, usually ";", to be used to to separate the names in the returned list.

Details

Only the first character of *listSepStr* is used.

ProcGlobal is not in the returned list, and the order of returned names is not defined.

See Also

Independent Modules on page IV-214.

GetIndependentModuleName, **StringFromList**, **FunctionList**.

IndexedDir

```
IndexedDir(pathName, index, flags)
```

The IndexedDir function returns a string containing the name of or the full path to the *index*th folder in the folder referenced by *pathName*.

Parameters

pathName is the name of an Igor symbolic path pointing to the parent directory.

index is the index number of the directory (within the parent directory) of interest starting from 0. If *index* is -1, IndexedDir will return the name of *all* of the folders in the parent, separated by semicolons.

flags is a bitwise parameter:

Bit 0:	Set if you want a full path. Cleared if you want just the directory name.

All other bits are reserved and should be cleared.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

Details

You create the symbolic path identifying the parent directory using the **NewPath** operation or the New Path dialog (Misc menu).

Prior to Igor Pro 3.1, IndexedDir was an external function and took a string as the first parameter rather than a name. The *pathName* parameter can now be either a name or a string containing a name. Any of the following will work:

```
String str = "IGOR"
Print IndexedDir(IGOR, 0, 0)         // First parameter is a name.
Print IndexedDir($str, 0, 0)         // First parameter is a name.
Print IndexedDir("IGOR", 0, 0)       // First parameter is a string.
Print IndexedDir(str, 0, 0)          // First parameter is a string.
```

The acceptance of a string is for backward compatibility only. New code should be written using a name.

The returned path uses the native conventions of the OS under which Igor is running.

Examples

Here is an example for heavy-duty Igor Pro programmers. It is an Igor Pro user-defined function that prints the paths of all of the files and folders in a given folder with or without recursion. You can rework this to do something with each file instead of just printing its path.

To try the function, copy and paste it into the Procedure window. Then execute the example shown in the comments.

```
// PrintFoldersAndFiles(pathName, extension, recurse, level)
// Shows how to recursively find all files in a folder and subfolders.
// pathName is the name of an Igor symbolic path that you created
// using NewPath or the Misc->New Path menu item.
// extension is a file name extension like ".txt" or "????" for all files.
// recurse is 1 to recurse or 0 to list just the top-level folder.
// level is the recursion level - pass 0 when calling PrintFoldersAndFiles.
// Example: PrintFoldersAndFiles("Igor", ".ihf", 1, 0)
Function PrintFoldersAndFiles(pathName, extension, recurse, level)
   String pathName     // Name of symbolic path in which to look for folders and files.
   String extension    // File name extension (e.g., ".txt") or "????" for all files.
   Variable recurse    // True to recurse (do it for subfolders too).
   Variable level      // Recursion level. Pass 0 for the top level.

   Variable folderIndex, fileIndex
   String prefix

   // Build a prefix (a number of tabs to indicate the folder level by indentation)
   prefix = ""
   folderIndex = 0
   do
      if (folderIndex >= level)
         break
      endif
      prefix += "\t"      // Indent one more tab
      folderIndex += 1
   while(1)

   // Print folder
   String path
   PathInfo $pathName     // Sets S_path
   path = S_path
   Printf "%s%s\r", prefix, path

   // Print files
   fileIndex = 0
   do
      String fileName
      fileName = IndexedFile($pathName, fileIndex, extension)
      if (strlen(fileName) == 0)
         break
      endif
      Printf "%s\t%s%s\r", prefix, path, fileName
      fileIndex += 1
   while(1)

   if (recurse)           // Do we want to go into subfolder?
      folderIndex = 0
      do
         path = IndexedDir($pathName, folderIndex, 1)
         if (strlen(path) == 0)
            break        // No more folders
         endif
```

```
            String subFolderPathName = "tempPrintFoldersPath_" + num2istr(level+1)

            // Now we get the path to the new parent folder
            String subFolderPath
            subFolderPath = path

            NewPath/Q/O $subFolderPathName, subFolderPath
            PrintFoldersAndFiles(subFolderPathName, extension, recurse, level+1)
            KillPath/Z $subFolderPathName

            folderIndex += 1
        while(1)
    endif
End
```

IndexedFile

IndexedFile(*pathName*, *index*, *fileTypeOrExtStr* [, *creatorStr*])

The IndexedFile function returns a string containing the name of the *index*th file in the folder specified by *pathName* which matches the file type or extension specified by *fileTypeOrExtStr*.

Details

IndexedFile returns an empty string ("") if there is no such file.

pathName is the *name* of an Igor symbolic path. It is *not* a string.

index normally starts from zero. However, if *index* is -1, IndexedFile returns a string containing a semicolon-separated list of the names of all files in the folder associated with the specified symbolic path which match *fileTypeOrExtStr*.

fileTypeOrExtStr is either:

- A string starting with ".", such as ".txt", ".bwav", or ".c". Only files with a matching file name extension are indexed. Set *fileTypeOrExtStr* to "." to index file names that end with "." such as "myFileNameEndsWithThisDot."
- A string containing exactly four characters, such as "TEXT" or "IGBW". Only files of the specified Macintosh file type are indexed. However, if *fileTypeOrExtStr* is "????", files of any type are indexed.

  On Windows, Igor considers files with ".txt" extensions to be of type TEXT. It does similar mappings for other extensions. See **File Types and Extensions** on page III-404 for details.

creatorStr is an optional string argument containing four characters such as "IGR0". Only files with the specified Macintosh creator code are indexed. Set *creatorStr* to "????" to index all files (or omit the argument altogether). This argument is ignored on Windows systems.

Treatment of Macintosh Dot-Underscore Files

As of Igor Pro 6.10, IndexedFile ignores "dot-underscore" files unless fileTypeOrExtStr is "????".

A dot-underscore file is a file created by Macintosh when it writes to a non-HFS volume, for example, when it writes to a Windows volume via SMB file sharing. The dot-underscore file stores Macintosh HFS-specific data such as the file's type and creator codes, and the file's resource fork, if it has one.

For example, if a file named "wave0.ibw" is copied via SMB to a Windows volume, Mac OS X creates two files on the Windows volume: "wave0.ibw" and "._wave0.ibw". Mac OS X makes these two files appear as one to Macintosh applications. However, Windows does not do this. As a consequence, when a Windows program sees "._wave0.ibw", it expects it to be a valid .ibw file, but it is not. This causes problems.

By ignoring dot-underscore files, IndexedFile prevents this type of problem. However, if fileTypeOrExtStr is "????", IndexedFile will return dot-underscore files on Windows.

Examples

```
NewPath/O myPath "MyDisk:MyFolder:"
Print IndexedFile(myPath,-1,"TEXT")         // all text-type files
Print IndexedFile(myPath,0,"TEXT")          // only the first text file
Print IndexedFile(myPath,-1,".dat")         // *.dat
Print IndexedFile(myPath,-1,"TEXT","IGR0")  // all Igor text files
Print IndexedFile(myPath,-1,"????")         // all files, all creators
```

See **IndexedDir** for another example using IndexedFile.

See Also
The **TextFile** and **IndexedDir** functions.

IndexSort

IndexSort [**/DIML**] ***indexWaveName, sortedWaveName*** [**, *sortedWaveName***]…

The IndexSort operation sorts the values in each *sortedWaveName* wave according to the Y values of *indexWaveName*.

Flags

/DIML Moves the dimension labels with the values (keeps any row dimension label with the row's value).

Details

indexWaveName can not be complex. *indexWaveName* is presumed to have been the destination of a previous **MakeIndex** operation.

This has the effect of putting the *sortedWaveName* waves in the same order as the wave from which the index values in *indexWaveName* was made.

All of the *sortedWaveName* waves must be of equal length.

See Also
MakeIndex and IndexSort Operations on page III-137.

Inf

Inf

The Inf function returns the "infinity" value.

InsertPoints

InsertPoints [**/M=*dim***] ***beforePoint, numPoints, waveName*** [**, *waveName***]…

The InsertPoints operation inserts *numPoints* points in front of point *beforePoint* in each *waveName*. The new points have the value zero.

Flags

/M=*dim* Specifies the dimension into which elements are to be inserted. Values are 0 for rows, 1 for columns, 2 for layers, 3 for chunks. If /M is omitted, InsertPoints inserts in the rows dimension.

Details

Trying to insert points into any but the rows of a zero-point wave results in a zero-point wave. You must first make the number of rows nonzero before anything else has an effect.

See Also
Lists of Values on page II-96.

Integrate

Integrate [***type flags***][***flags***] ***yWaveA*** [**/X = *xWaveA***][**/D = *destWaveA***]
[, ***yWaveB*** [**/X = *xWaveB***][**/D = *destWaveB***][**, …**]]

The Integrate operation calculates the 1D numeric integral of a wave. X values may be supplied by the X-scaling of the source wave or by an optional X wave. Rectangular integration is used by default.

Flags

/DIM= *d* Specifies the wave dimension along which to differentiate when yWave is multi-dimensional.

d=-1: Treats entire wave as 1D (default).

For *d*=0, 1, 2, 3, operates along rows, columns, layers or chunks.

For example, for a 2D wave, /DIM=0 integrates each row and /DIM=1 integrates each column.

/METH=*m* Sets the integration method.

m=0: Rectangular integration (default). Results at a point are stored at the same point (rather than at the next point as for /METH=2). This method keeps the dimension size the same.

m=1: Trapezoidal integration.

m=2: Rectangular integration. Results at a point are stored at the next point (rather than at the same point as for /METH=0). This method increases the dimension size by one to provide a place for the last bin.

/P Forces point scaling.

/T Trapezoidal integration. Same as /METH=1.

Type Flags *(used only in functions)*

Integrate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-58 and **WAVE Reference Type Flags** on page IV-58 for a complete list of type flags and further details.

Wave Parameters

Note: ***All*** wave parameters must follow *yWave* in the command. All wave parameter flags and type flags must appear immediately after the operation name (`Integrate`).

/D=*destWave* Specifies the name of the wave to hold the integrated data. It creates *destWave* if it does not already exist or overwrites it if it exists.

/X=*xWave* Specifies the name of corresponding X wave. For rectangular integration, the number of points in the X wave must be one greater than the number of elements in the Y wave dimension being integrated.

Details

The computation equation for rectangular integration using /METH=0 is:

$$waveOut[p] = \sum_{i=0}^{p} waveIn[i] \cdot [x_{i+1} - x_i] .$$

The computation equation for rectangular integration using /METH=2 is:

$$waveOut[0] = 0$$

$$waveOut[p+1] = \sum_{i=0}^{p} waveIn[i] \cdot [x_{i+1} - x_i] .$$

The inverse of this rectangular integration is the backwards difference.

Trapezoidal integration (/METH=1) is a more accurate method of computing the integral than rectangular integration. The computation equation is:

$$waveOut[0] = 0$$

$$waveOut[p] = waveOut[p-1] + \frac{waveIn[p-1] + waveIn[p]}{2} \cdot [x_p - x_{p-1}] .$$

If the optional /D = *destWave* flag is omitted, then the wave is integrated in place overwriting the source wave.

When using an X wave, the X wave must be a 1D wave with data type matching the Y wave (excluding the complex type flag). Rectangular integration (/METH=0 or 2) requires an X wave having one more point than the number of elements in the dimension of the Y wave being integrated. X waves with number points plus one are allowed for rectangular integration with methods needing only the number of points. X waves are not used with integer source waves.

Although it is mathematically suspect, rectangular integration using /METH=0 would be correct if the X scaling of the output wave is offset by ΔX.

`Differentiate/METH=1/EP=1` is the inverse of `Integrate/METH=2`, but `Integrate/METH=2` is the inverse of `Differentiate/METH=1/EP=1` only if the original first data point is added to the output wave.

Integrate applied to an XY pair of waves does not check the ordering of the X values and doesn't care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves first (see **Sort**).

The **Differentiate** operation. The **Integrate1D**, **area** and **areaXY** functions.

Integrate1D

Integrate1D(*UserFunctionName*, *min_x*, *max_x* [, *options* [, *count*]])

The Integrate1D function performs numerical integration of a user function between the specified limits (*min_x* and *max_x*).

Parameters

UserFunctionName must have the following format:

```
Function UserFunctionName(inX)
    Variable inX
    ... do something
    return result
End
```

options is one of the following:

0: Trapezoidal integration (default).

1: Romberg integration.

2: Gaussian Quadrature integration.

By default, *options* is 0 and the function performs trapezoidal integration. In this case Igor evaluates the integral iteratively. In each iteration the number of points where Igor evaluates the function increases by a factor of 2. The iterations terminate at convergence to tolerance or when the number of evaluations is 2^{23}.

The *count* parameter specifies the number of subintervals in which the integral is evaluated. If you specify 0 or a negative number for count, the function performs an adaptive Gaussian Quadrature integration in which Igor bisects the interval and performs a recursive refining of the integration only in parts of the interval where the integral does not converge to tolerance.

Details

You can integrate complex-valued functions using a function with the format:

```
Function/C complexUserFunction(inX)
    Variable inX
    Variable/C result
    //… do something
    return result
End
```

The syntax used to invoke the function is:

```
Variable/C cIntegralResult=Integrate1D(complexUserFunction,min_x,max_x…)
```

You can also use Integrate1D to perform a higher dimensional integrals. For example, consider the function: $F(x,y) = 2x + 3y + xy$.

In this case, the integral $h = \int dy \int f(x,y)dx$ can be performed by establishing two user functions:

```
Function Do2dIntegration(xmin,xmax,ymin,ymax)
    Variable xmin,xmax,ymin,ymax

    Variable/G globalXmin=xmin
    Variable/G globalXmax=xmax
    Variable/G globalY

    return Integrate1d(userFunction2,ymin,ymax,1)  // Romberg integration
End

Function UserFunction1(inX)
    Variable inX

    NVAR globalY=globalY

    return (3*inX+2*globalY+inX*globalY)
End
```

```
Function UserFunction2(inY)
   Variable inY

   NVAR globalY=globalY
   globalY=inY
   NVAR globalXmin=globalXmin
   NVAR globalXmax=globalXmax

   // Romberg integration
   return Integrate1D(userFunction1,globalXmin,globalXmax,1)
End
```

This method can be extended to higher dimensions.

If the integration fails to converge or if the integrand diverges, Integrate1D returns NaN. When a function fails to converge it is a good idea to try another integration method or to use a user-defined number of intervals (as specified by the count parameter). Note that the trapezoidal method is prone to convergence problems when the absolute value of the integral is very small.

The **Integrate** operation.

IntegrateODE

IntegrateODE [***flags***] ***derivFunc, cwaveName, ywaveSpec***

The IntegrateODE operation calculates a numerical solution to a set of coupled ordinary differential equations by integrating derivatives. The derivatives are user-specified via a user-defined function, *derivFunc*. The equations must be a set of first-order equations; a single second-order equation must be recast as two first-order equations, a third-order equation to three first order equations, etc. For more details on how to write the function, see **Solving Differential Equations** on page III-268.

IntegrateODE offers two ways to specify the values of the independent variable (commonly called X or t) at which output Y values are recorded. You can specify the X values or you can request a "free-run" mode.

The algorithms used by IntegrateODE calculate results at intervals that vary according to the characteristics of the ODE system and the required accuracy. You can set specific X values where you need output (see the /X flag below) and arrangements will be made to get values at those specific X values. In between those values, IntegrateODE will calculate whatever spacing is needed, but intermediate values will not be output to you.

If you specify free-run mode, IntegrateODE will simply output all steps taken regardless of the spacing of the X values that results.

Parameters

cwaveName Name of wave containing constant coefficients to be passed to *derivFunc*.

derivFunc Name of user function that calculates derivatives. For details on the form of the function, see **Solving Differential Equations** on page III-268.

ywaveSpec Specifies a wave or waves to receive calculated results. The waves also contain initial conditions. The *ywaveSpec* can have either of two forms:

ywaveName: *ywaveName* is a single, multicolumn wave having one column for each equation in your equation set (if you have just one equation, the wave will be a simple 1D wave).

{*ywave0*, *ywave1*, …}: The *ywaveSpec* is a list of 1D waves, one wave for each equation. The ordering is important — it must correspond to the elements of the y wave and dydx wave passed to *derivFunc*.

Unless you use the /R flag to alter the start point, the solution to the equations is calculated at each point in the waves, starting with row 1. You must store the initial conditions in row 0.

Flags

/CVOP={*solver*, *jacobian*, *extendedErrors* [, *maxStep*]}

Selects options that affect how the Adams-Moulton and BDF integration schemes operate. This flag applies only when using /M = 2 or /M = 3. These methods are based on the CVODE package, hence the flag letters "CV".

The *solver* parameter selects a solver method for each step. The values of *solver* can be:

solver=0: Select the default for the integration method. That is functional for /M=2 or Newton for /M=3.

solver=1: Functional solver.

solver=2: Newton solver.

The *jacobian* parameter selects the method used to approximate the jacobian matrix (matrix of df/dy_i where f is the derivative function).

jacobian=0: Full jacobian matrix.

jacobian=1: Diagonal approximation.

In both cases, the derivatives are approximated by finite differences.

In our experience, *jacobian* = 1 causes the integration to proceed by much smaller steps. It might decrease overall integration time by reducing the computation required to approximate the jacobian matrix.

If the *extendedErrors* parameter is nonzero, extra error information will be printed to the history window in case of an error during integration using /M=2 or /M=3. This extra information is mostly of the sort that will be meaningful only to WaveMetrics software engineers, but may occasionally help you to solve problems. It is printed out as a bug message (`BUG: . . .`) regardless of whether it is our bug or yours.

If *maxStep* is present and greater than zero, this option sets the maximum internal step size that the CVODE package is allowed to take. This is particularly useful with /M=3, as the BDF method is capable of taking extremely large steps if the derivatives don't change much. Use of this option may be necessary to make sure that the CVODE package doesn't step right over a brief excursion in, say, a forcing function. If you have something in your derivative function that may be step-like and brief, set *maxStep* to something smaller than the duration of the excursion.

If you want to set *maxStep* only, set the other three options to zero.

/E=*eps* Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a fraction of a scaled number. The fraction is *eps*. For instance, to achieve error less than one part in a thousand, set *eps* to 0.001. The number itself is set by a combination of the /F flag and possibly the wave specified with the /S flag. See **Solving Differential Equations** on page III-268 for details.

If you do not use the /E flag, *eps* is set to 10^{-6}.

For details, see **Error Monitoring** on page III-278.

/F=*errMethod* Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a scaled number. *errMethod* is a bitwise value that specifies what to include in that number:

bit 0: Add a constant from the error scaling wave set by the /S flag.

bit 1: Add the current value of the results.

bit 2: Add the current value of the derivatives.

bit 3: Multiply by the current step size (/M=0 or /M=1 only).

Each bit that you set of bits 0, 1, or 2 adds a term to the number; setting bit 3 multiplies the sum by the current step size to achieve a global error limit. Note that bit 3 has no effect if you use the Adams or BDF integrators (/M=2 or /M=3). See **Setting Bit Parameters** on page IV-12 for further details about bit settings.

If you don't include the /F flag, a constant is used. Unless you use the /S flag, that constant is set to 1.0.

For details, see **Error Monitoring** on page III-278.

/M=*m* Specifies the method to use in calculating the solution.

m=0: Fifth-order Runge-Kutta-Fehlberg (default).

m=1: Bulirsch-Stoer method using Richardson extrapolation.

m=2: Adams-Moulton method.

m=3: BDF (Backwards Differentiation Formula, or Gear method). This method is the preferred method for stiff problems.

If you don't specify a method, the default is the Runge-Kutta method (*m*=0). Bulirsch-Stoer (*m*=1) should be faster than Runge-Kutta for problems with smooth solutions, but we find that this is often not the case. Simple experiments indicate that Adams-

Moulton (*m*=2 may be fastest for nonstiff problems. BDF (*m*=3) is definitely the preferred one for stiff problems. Runge-Kutta is a robust method that may work on problems that fail with other methods.

/Q [= *quiet*]
quiet = 1 or simply /Q sets quiet mode. In quiet mode, no messages are printed in the history, and errors do not cause macro abort. The variable V_flag returns an error code. See **Details** for the meanings of the V_flag error codes.

/R=(*startX*,*endX*)
Specifies an X range of the waves in *ywaveSpec*.

/R=[*startP*,*endP*]
Specifies a point range in *ywaveSpec*.

If you specify the range as /R=[*startP*] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is evaluated. If you specify only the end point (/R = [,*endP*]) the start point is taken as point 0.

You must store initial conditions in *startP*. The first point is *startP*+1.

/S=*errScaleWaveName*
If you set bit 0 of *errMethod* using the /F flag, or if you don't include the /F flag, a constant is required for scaling the estimated error for each differential equation. By default, the constants are simply set to 1.0.

You provide custom values of the constants via the /S flag and a wave. Make a wave having one element for each derivative, set a reasonable scale factor for the corresponding equation, and set *errScaleWaveName* to the name of that wave.

If you don't use the /S flag, the constants are all set to 1.0.

/STOP = {*stopWave*, *mode*}
Requests that IntegrateODE stop when certain conditions are met on either the solution values (Y values) or the derivatives.

stopWave contains information that IntegrateODE uses to determine when to stop.

mode = 0: OR mode. If *stopWave* contains more than one condition, any one condition will stop the integration when it is satisfied.

mode = 1: AND mode. If *stopWave* contains more than one condition, all conditions must be satisfied to cause the integration to stop.

See Details, below, for more information.

/U=*u*
Update the display every *u* points. By default, it will update the display every 10 points. To disable updates, set *u* to a very large number.

/X=*xvaluespec*
Specifies the values of the independent variable (commonly called x or t) at which values are to be calculated (see parameter *ywaveSpec*).

You can provide a wave or *x0* and *deltaX*:

/X = *xWaveName*

Use this form to provide a list of values for the independent variable. They can have arbitrary spacing and may increase or decrease, but should be monotonic.

If you use the /XRUN flag to specify free-run mode, /X = *xWaveName* is required. In this case, the X wave becomes and output wave and any contents are overwritten. See the description of /XRUN for details.

xValues = {*x0, deltaX*}

If you use this form, *x0* is the initial value of the independent variable. This is the value at which the initial conditions apply. It will calculate the first result at *x0*+*deltaX*, and subsequent results with spacing of *deltaX*.

deltaX can be negative.

If you do not use the xValues keyword, it reads independent variable values from the X scaling of the results wave (see *ywaveSpec* parameter).

/XRUN={*dx0, Xmax*}
If *dx0* is nonzero, the output is generated in a free-running mode. That is, the output values are generated at whatever values if the independent variable (*x* or *t*) the integration method requires to achieve the requested accuracy. Thus, you will get solution points at variably-spaced X values.

The parameter *dx0* sets the step size for the first integration step. If this is smaller than necessary, the step size will increase rapidly. If it is too large for the requested accuracy, the integration method will decrease the step size as necessary.

If *dx0* is set to zero, free-run mode is not used; this is the same as if the XRUN flag is not used.

When using free-run mode, you must provide an X wave using /X = *xWaveName*. Set the first value of the wave (this is usually point zero, but may not be if you use the /R flag) to the initial value of X.

As the integration proceeds, the X value reached for each output point is written into the X wave. The integration stops when the latest step taken goes beyond *Xmax* or when the output waves are filled.

Details

The various waves you may use with the IntegrateODE operation must meet certain criteria. The wave to receive the results (*ywaveSpec*), and which contains the initial conditions, must have exactly one column for each equation in your system of equations, or you must supply a list of waves containing one wave for each equation. Because IntegrateODE can't determine how many equations there are from your function, it uses the number of columns or the number of waves in the list to determine the number of equations.

If you supply a list of waves for *ywaveSpec*, all the waves must have the same number of rows. If you supply a wave containing values of the independent variable or to receive X values in free-run mode (using /X=*waveName*) the wave must have the same number of rows as the *ywaveSpec* waves.

The wave you provide for error scaling via the /S flag must have one point for each equation. That is, one point for each *ywaveSpec* wave, or one point for each column of a multicolumn *ywaveSpec*.

By default, the display will update after each tenth point is calculated. If you display one of your *ywaveSpec* waves in a graph, you can watch the progress of the integration.

The display update may slow down the calculation considerably. Use the /U flag to change the interval between updates. To disable the updates entirely, set the update interval to a number larger than the length of the waves in *ywaveSpec*.

In free-run mode, it is impossible to predict how many output values you will get. IntegrateODE will stop when either your waves are filled, or when the X value exceeds *Xmax* set in the /XRUN flag. The best strategy is to make the waves quite large; unused rows in the waves will not be touched. To avoid having "funny" traces on a graph, you can prefill your waves with NaN. Make sure that you don't set the initial condition row and initial X value row to Nan!

Stopping IntegrateODE

In some circumstances it is useful to be able to stop the integration early, before the full number of output values has been computed. You can do this two ways: using the /STOP flag to put conditions on the solution, or by returning 1 from your derivative function.

When using /STOP={*stopWave*, *mode*}, *stopWave* must have one column for each equation in your system or, equivalently, a number of columns equal to the order of your system. Each column represents a condition on either the solution value or the derivatives for a given equation in your system.

Row 0 of *stopWave* contains a flag telling what sort of condition to apply to the solution values. If the flag is zero, that value is ignored. If the flag is 1, the integration is stopped if the solution value exceeds the value you put in row 1. If the flag is -1, integration is stopped when the solution value is less than the value in row 1.

Rows 2 and 3 work just like rows 0 and 1, but the conditions are applied to the derivatives rather than to the solution values.

If *stopWave* has two rows, only the solution values are checked. If *stopWave* has four rows, you can specify conditions on both solution values and derivatives.

You can set more than one flag value non-zero. If you do that, then *mode* determines how the multiple conditions are applied. If *mode* is 0, then any one condition can stop integration when it is satisfied. If *mode* is 1, all conditions with a non-zero flag value must be satisfied at the same time. If row 0 and row 2 have nothing but zeroes, then *stopWave* is ignored.

For further discussion, see **Stopping IntegrateODE on a Condition** on page III-281.

Output Variables

The IntegrateODE operation sets a variety of variables to give you information about the integration. These variables are updated at the same time as the display so you can monitor an integration in progress. They are:

V_ODEStepCompleted	Point number of the last result calculated.
V_ODEStepSize	Size of the last step in the calculation.
V_ODETotalSteps	Total number of steps required to arrive at the current result. In free-run mode, this is the same as V_ODEStepCompleted.
V_ODEMinStep	Minimum step size used during the entire calculation.
V_ODEFunctionCalls	The total number of calls made to your derivative function.

In Quiet mode (see the /Q flag) an V_Flag is set when IntegrateODE stops to indicate why it stopped:

V_flag — Set only in Quiet mode. Value indicates reason that IntegrateODE stopped. The values are:

- 0: Finished normally.
- 1: User aborted the integration.
- 2: Integration stopped because the step size became too small. That is, dX was so small that X + dX = X.
- 3: IntegrateODE ran out of memory.
- 4: In /M=2 or /M=3, the integrator received illegal inputs. Please report this to WaveMetrics (see **Technical Support** on page II-15 for contact details).
- 5: In /M=2 or /M=3, the integrator stopped with a failure in the step solver. The method chosen may not be suitable to the problem.
- 6: Indicates a bug in IntegrateODE. Please report this to WaveMetrics (see **Technical Support** on page II-15 for contact details).
- 7: An error scaling factor was zero (see /S and /F flags).
- 8: IntegrateODE stopped because the conditions specified by the /STOP flag were met.
- 9: IntegrateODE stopped because the derivative function returned a value requesting the stop.

interp

interp(*x1, xwaveName, ywaveName*)

The interp function returns a linearly interpolated value at the location x = *x1* of a curve whose X components come from the Y values of *xwaveName* and whose y components come from the Y values of *ywaveName*.

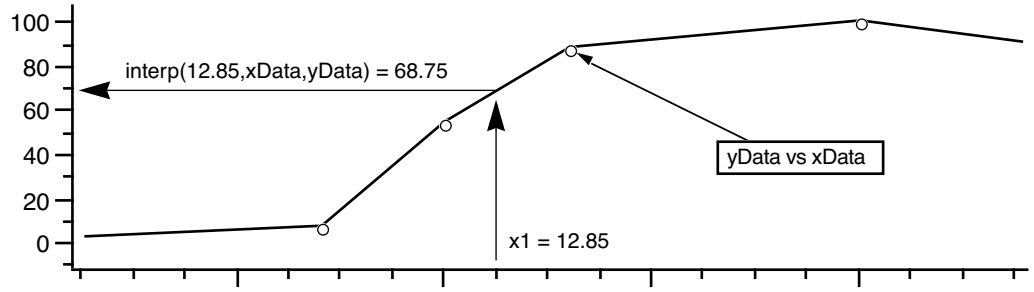
Details

interp returns nonsense if the waves are complex or if *xwaveName* is not monotonic.

The interp function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-110 for details.

Examples

Examples



See Also

The Interpolate XOP can also do linear as well as spline interpolation.

The **Loess**, **ImageInterpolate**, **Interpolate3D**, and **Interp3DPath** operations.

The **Interp2D**, **Interp3D** and **ContourZ** functions.

Interp2D

Interp2D(*srcWaveName, xValue, yValue*)

The Interp2D function returns a double precision number as the interpolated value for the *xValue*, *yValue* point in the source wave. Returns NaN if the point is outside the source wave domain or if the source wave is complex.

Parameters

srcWaveName is the name of a 2D wave. The wave can not be complex.

xValue is the X-location of the interpolated point.

yValue is the Y-location of the interpolated point.

See Also

The **ImageInterpolate** operation. **Interpolation** on page III-121.

Interp3D

Interp3D(*srcWave, x, y, z* [, *triangulationWave*])

The Interp3D function returns an interpolated value for location P=(*x*, *y*, *z*) in a 3D scalar distribution *srcWave*.

If *srcWave* is a 3D wave containing a scalar distribution sampled on a regular lattice, the function returns a linearly interpolated value for any P=(*x*, *y*, *z*) location within the domain of *srcWave*. If P is outside the domain, the function returns NaN.

To interpolate a 3D scalar distribution that is not sampled on a regular lattice, *srcWave* is a four column 2D wave where the columns correspond to *x*, *y*, *z*, f(*z*, *y*, *z*), respectively. You must also use a "triangulation" wave for *srcWave* (use `Triangulate3D/out=1` to obtain the triangulation wave). If P falls within the convex domain defined by the tetrahedra in *triangulationWave*, the function returns the barycentric linear interpolation for P using the tetrahedron where P is found. If P is outside the convex domain the function returns NaN.

Examples

```
Make/O/N=(10,20,30) ddd=gnoise(10)
Print interp3D(ddd,1,0,0)
Print interp3D(ddd,1,1,1)
```

```
Make/O/N=(10,4) ddd=gnoise(10)
Triangulate3D/OUT=1 ddd
Print interp3D(ddd,1,0,0,M_3DVertexList)
Print interp3D(ddd,1,1,1,M_3DVertexList)
```

See Also

The **Interpolate3D** operation. **Interpolation** on page III-121.

Interp3DPath

Interp3DPath *3dWave tripletPathWave*

The Interp3DPath operation computes the trilinear interpolated values of *3dWave* for each position specified by a row of in *tripletPathWave*, which is a three-column wave in which the first column represents the X coordinate, the second represents the Y coordinate and the third represents the Z coordinate. Interp3DPath stores the resulting interpolated values in the wave W_Interpolated. Interp3DPath is equivalent to calling the Interp3D() function for each row in *tripletPathWave* but it is computationally more efficient.

If the position specified by the *tripletPathWave* is outside the definition of the *3dWave* or if it contains a NaN, the operation stores a NaN in the corresponding output entry.

Both *3dWave* and *tripletPathWave* can be of any numeric type. W_Interpolated is always of type NT_FP64.

See Also

The **ImageInterpolate** operation and the **Interp3D** and **interp** functions. **Interpolation** on page III-121.

Interpolate3D

Interpolate3D [/Z] /RNGX={*x0,dx,nx*}/RNGY={*y0,dy,ny*}/RNGZ={*z0,dz,nz*}
/DEST=*dataFolderAndName*, triangulationWave=*tWave*, srcWave=*sWave*

The Interpolate3D operation uses a precomputed triangulation of *sWave* (see **Triangulate3D**) to calculate regularly spaced interpolated values from an irregularly spaced source. The interpolated values are calculated for a lattice defined by the range flags /RNGX, /RNGY, and /RNGZ. *sWave* is a 4 column wave where the first three columns contain the spatial coordinates and the fourth column contains the associated scalar value. Interpolate3D is essentially equivalent to calling the **Interp3D** function for each interpolated point in the range but it is much more efficient.

Parameters

triangulationWave=*tWave*
: Specifies a 2D index wave, *tWave*, in which each row corresponds to one tetrahedron and each column (tetrahedron vertex) is represented by an index of a row in *sWave*. Use **Triangulate3D** with /OUT=1 to obtain *tWave*.

srcWave=*sWave*
: Specifies a real-valued 4 column 2D source wave, *sWave*, in which columns correspond to *x*, *y*, *z*, f(*x*, *y*, *z*). Requires that the domain occupied by the set of {*x*, *y*, *z*} be convex.

Flags

/DEST=*dataFolderAndName*
: Saves the result in the specified destination wave. The destination wave will be created or overwritten if it already exists. *dataFolderAndName* can include a full or partial path with the wave name.

/RNGX={*x0*,*dx*,*nx*}
: Specifies the range along the X-axis. The interpolated values start at *x0*. There are *nx* equally spaced interpolated values where the last value is at *x0*+(*nx*-1)*dx*. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a YZ plane would have *nx*=1.

/RNGY={*y0*,*dy*,*ny*}
: Specifies the range along the Y-axis. The interpolated values start at *y0*. There are *nx* equally spaced interpolated values where the last value is at *y0*+(*ny*-1)*dy*. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XZ plane would have *ny*=1.

/RNGZ={*z0*,*dz*,*nz*}
: Specifies the range along the Z-axis. The interpolated values start at *z0*. There are *nz* equally spaced interpolated values where the last value is at *z0*+(*nz*-1)*dz*. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XY plane would have *nz*=1.

/Z
: No error reporting.

Details

The triangulation wave defines a set of tetrahedra that spans the convex source domain. If the requested range consists of points outside the domain, the interpolated values will be set to NaN. The interpolation process for points inside the convex domain consists of first finding the tetrahedron in which the point resides and then linearly interpolating the scalar value using the barycentric coordinate of the interpolated point.

In some cases the interpolation may result in NaN values for points that are clearly inside the convex domain. This may happen when the preceding Triangulate3D results in tetrahedra that are too thin. You can try using

Triangulate3D with the flag /OUT=4 to get more specific information about the triangulation. Alternatively you can introduce a slight random perturbation to the input source wave before the triangulation.

Example

```
Function Interpolate3DDemo()
    Make/O/N=(50,4) ddd=gnoise(20)    // First 3 columns store XYZ coordinates
    ddd[][3]=ddd[p][2]                // Fourth column stores a scalar which is set to z
    Triangulate3D ddd                 // Perform the triangulation
    Wave M_3dVertexList
    Interpolate3D /RNGX={-30,1,80}/RNGY={-40,1,80}/RNGZ={-40,1,80}
          /DEST=W_Interp triangulationWave=M_3dVertexList,srcWave=ddd
End
```

References

Schneider, P.J., and D. H. Eberly, *Geometric Tools for Computer Graphics*, Morgan Kaufmann, 2003.

inverseErf

inverseErf(*x*)

The inverseErf function returns the inverse of the error function.

Details

The function is calculated using rational approximations in several regions followed by one iteration of Halley's algorithm.

See Also

The **erf**, **erfc**, **dawson**, and **inverseErfc** functions.

inverseErfc

inverseErfc(x)

The inverseErfc function returns the inverse of the complementary error function.

Details

The function is calculated using rational approximations in several regions followed by one iteration of Halley's algorithm.

See Also

The **erf**, **erfc**, **erfcw**, **dawson**, and **inverseErf** functions.

ItemsInList

ItemsInList(*listStr* [, *listSepStr*])

The ItemsInList function returns the number of items in *listStr*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use ItemsInList to count the number of items in a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

If *listStr* is `""` then 0 is returned.

listSepStr is optional. If missing, *listSepStr* is presumed to be ";".

Details

listStr is searched for item strings bound by *listSepStr* on the left and right.

An item can be empty. The lists `"abc;def;;ghi"` and `";abc;def;;ghi;"` have four items (the third item is `""`).

listStr is treated as if it ends with a *listSepStr* even if it doesn't. The search is case-sensitive.

Only the first character of *listSepStr* is used.

Examples

```
Print ItemsInList("wave0;wave1;wave1#1;")          // prints 3
Print ItemsInList("key1=val1,key2=val2", ",")      // prints 2
Print ItemsInList("1 \t 2 \t", "\t")               // prints 2
Print ItemsInList(";")                             // prints 1
Print ItemsInList(";;")                            // prints 2
Print ItemsInList(";a;")                           // prints 2
Print ItemsInList(";;;")                           // prints 3
```

See Also

The **AddListItem**, **StringFromList**, **FindListItem**, **RemoveFromList**, **WaveList**, **TraceNameList**, **StringList**, **VariableList**, and **FunctionList** functions.

j

j

The j function returns the loop index of the 2nd innermost iterate loop in a macro. Not to be used in a function. iterate loops are archaic and should not be used.

jlim

jlim

The jlim function returns the ending loop count for the 2nd inner most iterate loop. Not to be used in a function. iterate loops are archaic and should not be used.

JulianToDate

JulianToDate(*julianDay*, *format*)

The JulianToDate function returns a date string containing the day, month, and year. The input *julianDay* is truncated to an integer.

Parameters

julianDay is the Julian day to be converted.

format specifies the format of the returned date string.

format	Date String
0	mm/dd/year
1	dd/mm/year
2	Tuesday November 15, 2002
3	year mm dd
4	year/mm/dd

See Also

The **dateToJulian** function.

For more information about the Julian calendar see: <http://www.tondering.dk/claus/cal/>.

KillBackground

KillBackground

The KillBackground operation kills the unnamed background task.

KillBackground works only with the unnamed background task. New code should used named background tasks instead. See **Background Tasks** on page IV-279 for details.

Details

You can not call KillBackground from within the background function itself. However, if you return 1 from the background function, instead of the normal 0, Igor will terminate the background task.

See Also

The **BackgroundInfo**, **CtrlBackground**, **CtrlNamedBackground**, **SetBackground**, and **SetProcessSleep** operations; and **Background Tasks** on page IV-279.

KillControl

KillControl [**/W=*winName***] ***controlName***

The KillControl operation kills the named control in the top or specified graph or panel window or subwindow.

If the named control does not exist, KillControl does not complain.

Flags

/W=*winName* Looks for the control in the named graph or panel window or subwindow. If /W is omitted, KillControl looks in the top graph or panel window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

KillDataFolder

KillDataFolder [**/Z**] ***dataFolderSpec***

The KillDataFolder operation kills the specified data folder and everything in it including other data folders.

However, if *dataFolderSpec* is the name of a data folder reference variable that refers to a free data folder, the variable is cleared and the data folder is killed only if this is the last reference to that free data folder.

Flags

/Z No error reporting (except for setting V_flag). Does not halt function execution.

Parameters

dataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

Details

If specified data folder is the current data folder or contains the current data folder then Igor makes its parent the new current data folder.

For legacy reasons, a null data folder is taken to be the current data folder. This can happen when using a $ expression where the string might possibly evaluate to "".

It is legal to kill the root data folder. In this case the root data folder itself is not killed but everything in it is killed.

KillDataFolder generates an error if any of the waves involved are in use. In this case, nothing is killed.

KillDataFolder generates an error if any of the waves involved are in use. In this case, nothing is killed. Execution ceases unless /Z is specified.

The variable V_flag is set to 0 when there is no error, otherwise it is an error code.

Examples

```
KillDataFolder foo          // Kills foo in the current data folder.
KillDataFolder :bar:foo     // Kills foo in bar in current data folder.
String str= "root:foo"
KillDataFolder $str         // Kills foo in the root data folder.
```

See Also

Chapter II-8, **Data Folders** and the **KillStrings**, **KillVariables**, and **KillWaves** operations.

KillFIFO

KillFIFO ***FIFOName***

The KillFIFO operation discards the named FIFO.

Details

FIFOs are used for data acquisition.

If there is an output or review file associated with the FIFO, KillFIFO closes the file. If the FIFO is used by an XOP, you should call the XOP to release the FIFO before killing it.

See Also

See **FIFOs and Charts** on page IV-276 for information about FIFOs and data acquisition.

KillFreeAxis

KillFreeAxis [**/W=*winName***] ***axisName***

The KillFreeAxis operation removes a free axis specified by *axisName* from a graph window or subwindow.

Flags

/W=*winName* Kills the free axis in the named graph window or subwindow. If /W is omitted, it acts on the top graph window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Details

Only an axis created by **NewFreeAxis** can be killed and only if no traces or images are attached to the axis.

See Also

The **NewFreeAxis** operation.

KillPath

KillPath [**/A/Z**] ***pathName***

The KillPath operation removes a path from the list of symbolic paths. KillPath is a newer name for the **RemovePath** operation.

Flags

/A Kills all symbolic paths in the experiment except for the built-in paths. Omit *pathName* if you use /A.

/Z Does not generate an error if a path to be killed is a built-in path or does not exist. To kill all paths in the experiment, use `KillPath/A/Z`.

Details

You can't kill the built-in paths "home" and "Igor".

See Also

The **NewPath** operation.

KillPICTs

KillPICTs [**/A/Z**] [***PICTName*** [**,** ***PICTName***]…]

The KillPICTs operation removes one or more named pictures from the current Igor experiment.

Flags

/A Kills all pictures in the experiment.

/Z Does not generate an error if a picture to be killed is in use or does not exist. To kill all pictures in the experiment, use `KillPICTs/A/Z`.

Details

You can not kill a picture that is used in a graph or page layout.

Warning: You *can* kill a picture that is referenced from a graph or layout recreation macro. If you do, the graph or layout can not be completely recreated. Use the Find dialog (Edit menu) to locate references in the procedure window to a named picture you want to kill.

See Also

See **Pictures** on page III-421 for general information on how Igor handles pictures.

KillStrings

KillStrings [**/A/Z**] [***stringName*** [**, *stringName***]…]

The KillStrings operation discards the named global strings.

Flags

/A Kills all global strings in the current data folder. If you use /A, omit *stringName*.

/Z Does not generate an error if a global string to be killed does not exist. To kill all global strings in the current data folder, use `KillStrings/A/Z`.

KillVariables

KillVariables [**/A/Z**] [***variableName*** [**, *variableName***]…]

The KillVariables operation discards the named global numeric variables.

Flags

/A Kills all global variables in the current data folder. If you use /A, omit *variableName*.

/Z Does not generate an error if a global variable to be killed does not exist. To kill all global variables in the current data folder, use `KillVariables/A/Z`.

KillWaves

KillWaves [***flags***] ***waveName*** [**, *waveName***]…

The KillWaves operation destroys the named waves.

Flags

/A Kills all waves in the current data folder. If you use /A, omit *waveName*s.

/F Deletes the Igor binary file from which *waveName* was loaded.

/Z Does not generate an error if a wave to be killed is in use or does not exist.

Details

The memory the waves occupied becomes available for other uses. You can't kill a wave used in a graph, table or user defined function, or which is reserved by an XOP.

XOPs reserve a wave by sending the OBJINUSE message.

Examples

```
KillWaves/A/Z       // kill waves not in use in current data folder
```

KillWindow

KillWindow *winName*

The KillWindow operation kills or closes a specified window or subwindow without saving a recreation macro.

Parameters

winName is the name of an existing window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

See Also

The **DoWindow** operation.

KMeans

KMeans [***flags***] ***populationWave***

The KMeans operation analyzes the clustering of data in *populationWave* using an iterative algorithm. The result of KMeans is a specification of the classes which is saved in the wave M_KMClasses in the current data folder. Optional results include the distribution of class members (W_KMMembers) and the inter-class distances. *populationWave* is a 2D wave in which columns correspond to members of the population and rows contain the dimensional information.

Flags

/CAN
Analyzes the clustering by computing Euclidean distances between the means of the resulting classes. The resulting distances are stored in an NxN square matrix where N is the number of classes. Self distances (along the diagonal) or distances involving classes that did not survive the iterations are filled with NaN. Also saves the wave W_KMDispersion, which contains the sum of the distances between the center of each class and all its members. Distances are evaluated using the method specified by /DIST.

/DEAD=*method*
Specifies how the algorithm should handle "dead" classes, which are those that lose all members in a given iteration.

method=1: Remove the class if it looses all members.

method=2: Default; keeps the last value of the mean vector in case the class might get new members in a subsequent iteration.

method=3: Assigns the class a random mean vector.

/DIST=*mode*
Specifies how the class distances are evaluated.

mode=1: Distance is evaluated as the sum of the absolute values (also known as Manhattan distance).

mode=2: Default; distance is evaluated as Euclidean distance.

/INIT=*method*
Specifies the initialization method.

method=1: Random assignment of members of the population to a class.

method=2: User-specified mean values (/INW).

method=3: Default; initialize classes using values of a random selection from the population.

/INW=*iWave*
Sets the initial classes. The number of rows of *iWave* equals the dimensionality of the class and the number of columns of *iWave* is the number of classes. For example, if we want to initialize 5 classes in a problem that involves position in two dimensions then *iWave* must have 2 rows and 5 columns. The number of rows must also match the number of rows in *populationWave*.

/NCLS=*num*
Sets the number of classes in the data. If the initialization method uses specific means (/INIT=2) then the number of columns of *iWave* (see /INW) must match *num*. The default number of classes is 2.

/OUT=*format*
Specifies the format for the results.

format=1: Output only the specification of the classes in the 2D wave M_KMClasses (default). Each column in M_KMClasses represents a class. The number of rows in M_KMClasses is equal to the number of rows in `populationWave+1`. The last row contains the number of class members. The remaining rows represent the center of the class. For example, if *populationWave* has two rows then the dimensionality of the problem is 2 and M_KMClasses has 3 rows with the first row containing the first components of each class center, the second row containing the second components of each class center and the third row containing the number of elements in each class.

format=2: Output (in addition to M_KMClasses) the class membership in the wave W_KMMembers. The rows in this 1D wave correspond to sequential members of *populationWave* and the entries correspond to the (zero based) column number in M_KMClasses.

/SEED=*val*
Sets the seed for a new sequence in the pseudo-random number generator that is used by the operation. *val* must be an integer greater than zero.

By changing the sequence you may be able to find new solutions or just make the process converge at a different rate.

/TER=*method*
Determines when the iterations stop.

method=1: User-specified number of iterations (/TERN).

method=2: Default; continue iterating until no more than a fixed number of elements change classes in one iteration (TERN).

/TERN=*num*
Specifies the termination number. The meaning of the number is determined by /TER above. By default, the termination *method*=2 and the default value of the maximum number of elements that change classes in one iteration is 5% of the size of the population.

/Z No error reporting. If an error occurs, sets V_flag to -1 but does not halt function execution.

Details

KMeans uses an iterative algorithm to analyze the clustering of data. The algorithm is not guaranteed to find a global optimum (maximum likelihood solution) so the operation provides various flags to control when the iterations terminate. You can determine if the operation iterates a fixed number of times or loops until at most a specified maximum number of elements change class membership in a single iteration. If you are computing KMeans in more than one dimension you should pay attention to the relative magnitudes of the data in each dimension. For example, if your data is distributed on the interval [0,1] in the first dimension and on the interval [0,1e7] in the second dimension, the operation will be biased by the much larger magnitude of values in the second dimension.

Examples

Create data with 3 classes:

```
Make/O/N=(1,128) jack=4+gnoise(1)
jack[0][15,50]+=10
jack[0][60,]+=20
```

Perform KMeans looking for 5 classes:

```
KMeans/init=1/out=1/ter=1/dead=1/tern=1000/ncls=5 jack
Print M_KMClasses
  M_KMClasses[0][0]= {24.1439,68}
  M_KMClasses[0][1]= {14.1026,36}
  M_KMClasses[0][2]= {4.01537,24}
```

See Also

The **FPClustering** function.

A nice overview of k-means classification can be found at:
<http://www.ece.neu.edu/groups/rpl/projects/kmeans/index.html>.

Label

Label [**/W=*winName*/Z**] ***axisName, labelStr***

The Label operation labels the named axis with *labelStr*.

Parameters

axisName is the name of an existing axis in the top graph. It is usually one of “left”, “right”, “top” or “bottom”, though it may also be the name of a free axis such as “VertCrossing”.

labelStr contains the text that labels the axis.

Flags

/W=*winName* Adds axis label in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

/Z No errors generated if the named axis doesn’t exist. Used for style macros.

Details

labelStr can contain the following escape codes which affect subsequent characters in the string:

\B Use subscript (in smaller type).

\F'*fontName*' Use specified font (e.g., `\F'Helvetica'`).

\f*dd* *dd* is a binary coded number with each bit controlling one aspect of the column’s font style as follows:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

For example, bold underline is $2^0 + 2^2 = 1 + 4 = 5$. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

\K(*r*,*g*,*b*)	Use specified color for text. *r*, *g*, and *b* are integers from 0 to 65535.
\M	Use normal script (reverts to main line and font size).
).	
\S	Use superscript (in smaller type).
\Z*nn*	Use font size *nn*, which must be exactly two digits.

labelStr can also contain the following special codes that insert dynamically computed substrings:

\c	Inserts the name of the wave that controls the axis. This is the first wave graphed against that axis.
\E	Inserts power of 10 scaling with leading x. This can be ambiguous; we recommend that you use either \U or \u.
\e	Like \E but inverts the sign of the exponent. Even more ambiguous than \E.
\s(*traceName*)	Inserts a wave symbol for the named trace.
\U	Inserts units with automatic prefixes.
\u	Inserts power of 10 scaling but without the leading x as used by \E. No action if axis is not scaled. Use in front of custom or compound unit strings. Example label: "`Field Strength (\\u Volts/Meter)`" will produce something like "Field Strength (10^6 Volts/Meter)".
\u#1	This is a variant of \u that inserts the inverse of \u (e.g., 10^{-6} instead of 10^6).
\u#2	Prevents automatic insertion of any units or scaling. Normally, if you set a wave's units and scaling, using the Change Wave Scaling dialog or **SetScale** operation, and if you do not explicitly specify an axis label, Igor will automatically generate an axis label from the units and scaling. \u#2 provides a way to suppress this behavior when it gets in the way.

Note that escape codes are case sensitive; \u and \U insert different substrings.

labelStr can also contain other infrequently-used escape sequences as documented for the **TextBox** operation.

Each backslash character should be preceded with another backslash. This is because backslash is itself a special escape character for strings. Future Igor Pro versions may require this double-backslash syntax; currently either the single or double backslash are acceptable synonyms for inserting a single backslash into a string. For example:

```
String myStr = "\\"
Print myStr             // Prints \ to the history area
```

myStr was set to a *single* backslash character. See **Escape Characters in Strings** on page IV-13 for more about the backslash character. This behavior affects how escape sequences in *labelStr* should be written:

```
Label top, "\Z14Stuff"     // no: In future, may come out as "Z14Stuff"
Label top, "\\Z14Stuff"    // yes
```

You can see how *labelStr* should be constructed by using the Axis Label tab and observing the command it creates. You will observe many double backslash sequences. Single backslash sequences are deprecated, and are currently accepted for backward compatibility reasons.

The characters "<??>" in an axis label indicate that you specified an invalid escape code or used a font that is not available.

See Also

See **About Text Info Variables** on page III-64 for *labelStr* escape codes that manipulate text info variables. See **Escape Characters in Strings** on page IV-13 for more about the backslash character. See the **Legend** operation about wave symbols.

laguerre

laguerre(*n*, *x*)

The laguerre function returns the Laguerre polynomial of degree *n* (positive integer) and argument *x*. The polynomials satisfy the recurrence relation:

$$(n+1)Laguerre(n+1,x) = (2n+1-x)Laguerre(n,x) - nLaguerre(n-1,x)$$

with the initial conditions $Laguerre(0,x) = 1$ and $Laguerre(1,x) = 1-x$.

See Also

The **chebyshev**, **chebyshevU**, **hermite**, **hermiteGauss**, and **legendreA** functions.

laguerreA

laguerreA(*n*, *k*, *x*)

The laguerreA function returns the associated Laguerre polynomial of degree *n* (positive integer), index *k* (non-negative integer) and argument *x*. The associated Laguerre polynomials are defined by

$$L_n^k(x) = (-1)^k \frac{d^k}{dx^k}[L_{n+k}(x)]$$ where $L_{n+k}(x)$ is the Laguerre polynomial.

See Also

The **laguerre** and **laguerreGauss** functions.

References

Arfken, G., *Mathematical Methods for Physicists*, Academic Press, New York, 1985.

laguerreGauss

laguerreGauss(*p*, *m*, *r*)

The laguerreGauss function returns the normalized product of the associated Laguerre polynomials and a Gaussian. This function is typically encountered in solutions to physical problems where it represents the radial solution with an additional factor exp(i*m*ϕ) which is not included in this case. The LaguerreGauss is given by

$$U_{pm}(r) = \left[\frac{2p!}{\pi(m+p)!}\right]^{1/2} (\sqrt{2}r)^m L^m{}_p(2r^2)\exp(-r^2)$$

See Also

The **laguerre**, **laguerreA**, and **hermiteGauss** functions.

Layout

Layout [*flags*] [*objectSpec* [, *objectSpec*]…] [**as** *titleStr*]

The Layout operation creates a page layout.

Note: The Layout operation is antiquated and can not be used in user-defined functions. For new programming, use the **NewLayout** operation instead.

Parameters

All of the parameters are optional.

Each *objectSpec* parameter identifies a graph, table, textbox or picture to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See **Details**.

titleStr is a string expression containing the layout's title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

Flags

/A=(*rows*,*cols*)	Specifies rows and columns for tiling or stacking.
/B=(*r*,*g*,*b*)	Specifies the background color for the layout. *r*, *g*, and *b* are integers from 0 to 65535. Defaults to white (65535,65535, 65535).
/C=*colorOnScreen*	Obsolete. Prior to Igor Pro 5, this flag switched the screen display of the layout between black and white and color. Now layouts are always displayed in color. This flag has no effect but is still accepted.
/G=*g*	Specifies grout, the spacing between tiled objects. Units are points unless /I, /M, or /R are specified.
/HIDE=*h*	Hides (h = 1) or shows (h = 0, default) the window.

/I — Specifies that coordinates are in inches. This affects subsequent /G, /W, and *objectSpec* coordinates. Coordinates are relative to the top/left corner of the paper.

/K=*k* — Specifies window behavior when the user attempts to close it.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

k=3: Hides the window.

If you use /K=2 or /K=3, the only way to kill the window is via the DoWindow/K operation.

/M — Specifies that coordinates are in centimeters. This affects subsequent /G, /W, and *objectSpec* coordinates. Coordinates are relative to the top/left corner of the paper.

/P=*orientation* — *orientation* is either Portrait or Landscape (*e.g.*, `Layout/P= Landscape`). This controls the orientation of the page in the layout. See **Details**.

If you use the /P flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as /T and /G.

/R — Specifies that coordinates are in percent. This affects subsequent /G, /W, and *objectSpec* coordinates. For /W, coordinates are as a percent of the main screen. For /G and *objectSpec*, coordinates are relative to the top/left corner of the printing part of the page.

/S — Stacks objects.

/T — Tiles objects.

/W=(*left*, *top*, *right*, *bottom*) — Gives the layout window a specific location and size on the screen. Coordinates for /W are in points unless /I or /M are specified.

Details

The orientation of the page is controlled by the page setup record associated with the layout. When you create a brand new layout window, the page setup record comes from your preferred page setup (which you specify via the Capture Layout Prefs dialog) or from a default page setup that Igor creates by calling the current printer driver. When you recreate a layout window using a Window macro, Igor reuses the page setup originally used for the layout window.

If you use the /P flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as /T and /G.

The form of an *objectSpec* is:

```
objectName [(objLeft, objTop, objRight, objBottom)][/O=objType][/F=frame]
[/T=trans][/D=fidelity]
```

objectName can be the name of an existing graph, table or picture. It can also be the name of an object that does not yet exist. In this case it is called a "dummy object".

objectSpec can be specified using a string by using the $ operator, but the entire *objectSpec* must be in the string.

Here are some examples of valid usage:

```
Layout Graph0

Layout/I Graph0(1, 1, 6, 5)/F=1

String s = "Graph0"
Layout/I $s

String s = "Graph0(1, 1, 6, 5)/F=1"
Layout/I $s         // Entire object spec is in string.
```

The object's coordinates are determined as follows:

- If *objectName* is followed by a coordinates specification in (*objLeft*, *objTop*, *objRight*, *objBottom*) form then this sets the object's coordinates. The units for the coordinates are points unless the /I or /M flag was present in which case the units are inches or centimeters respectively.
- If the object coordinates are not specified explicitly but the Layout/S flag was present then the object is stacked. If the Layout/T flag was present then the object is tiled, and if the Layout/A=(*rows*,*cols*) flag is present, tiling is performed using that number of rows and columns.

- If the object's coordinates are not determined by these rules then the object is set to a default size and is stacked.

Each object has a type (graph, table, textbox or picture) determined as follows:

If the *objectName*/O=*objType* flag is present then it determines the object's type:

/O=*objType*	*objType*=1:	Graph.
	objType=2:	Table.
	objType=8:	Picture.
	objType=32:	Textbox.

If there is no /O flag and *objectName* is the name of an existing graph, table or picture, then the object type is graph, table or picture.

If the object's type is not determined by the above rules and *objectName* contains "Table", "PICT", or "TextBox", then the object type is table, picture or textbox.

If the object's type is not specified by any of the above rules, it is taken to be a graph type object.

The remaining flags have the following meanings:

/D=*fidelity*	*fidelity*=0:	Low fidelity display.
	fidelity=1:	High fidelity display (default).
/F=*frame*	*frame*=0:	No frame.
	frame=1:	Single frame (default).
	frame=2:	Double frame.
	frame=3:	Triple frame.
	frame=4:	Shadow frame.
/T=*trans*	*trans*=0:	Opaque (default).
	trans=1:	Transparent. For this to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. Pictures may have been created transparent or opaque, and Igor cannot make an inherently opaque picture transparent.

See Also

The **NewLayout** and **LayoutInfo** operations. See Chapter II-16, **Page Layouts**.

Layout

Layout

Layout is a procedure subtype keyword that identifies a macro as being a page layout recreation macro. It is automatically used when Igor creates a window recreation macro for a layout. See **Procedure Subtypes** on page IV-179 and **Killing and Recreating a Layout** on page II-369 for details.

See Also

See Chapter II-16, **Page Layouts**.

LayoutInfo

LayoutInfo(*winNameStr, itemNameStr*)

The LayoutInfo function returns a string containing a semicolon-separated list of keywords and values that describe an object in a page layout or overall properties of the page layout. The main purpose of LayoutInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges objects.

winNameStr is the name of an existing page layout window or "" to refer to the top layout.

itemNameStr is a string expression containing one of the following:

1. The name (e.g., "Graph0") of a layout object to get information about that object.
2. An object instance (e.g., "Graph0#0" or "Graph0#1") to get information about a particular instance of an object. This is of use only in the unusual situation when the same object appears in the layout multiple times. "Graph0#0" is equivalent to "Graph0". "Graph0#1" is the second occurrence of Graph0 in the layout.

3. An integer object index starting from zero to get information about an object referenced by its position in the layout. Zero refers to the first object going from back to front in the layout.
4. The word "Layout" to get overall information about the layout.

Details

In cases 1, 2 and 3 above, where *itemNameStr* references an object, the returned string contains the following keywords, with a semicolon after each keyword-value pair.

Keyword	Information Following Keyword
FIDELITY	Object fidelity expressed as a code usable in a ModifyLayout fidelity command.
FRAME	Object frame expressed as a code usable in a ModifyLayout frame command.
HEIGHT	Object height in points.
INDEX	Object position in the back-to-front order of the layout, starting from zero.
LEFT	Object left position in points.
NAME	The name of the object.
SELECTED	Zero if the object is not selected or nonzero if it is selected. You can identify the first-selected object by examining the SELECTED code of all objects. The one with the smallest nonzero selected code is the object that was first selected.
TOP	Object top position in points.
TRANS	Object transparency expressed as a code usable in a ModifyLayout trans command.
TYPE	Object type which is one of: Graph, Table, Picture, or Textbox.
WIDTH	Object width in points.

In case 4 above, where *itemNameStr* is "Layout", the returned string contains the following keywords, with a semicolon after each keyword-value pair.

Keyword	Information Following Keyword
BGRGB	Layout background color expressed as <red>, <green>, <blue> where each color is a value from 0 to 65535.
MAG	Layout magnification: 0.25, 0.5, 1.0, or 2.0.
NUMOJBECTS	Total number of objects in the layout.
NUMSELECTED	Number of selected objects.
PAGE	A rectangle defining the part of the paper that is inside the margins, expressed in points. The format is <left>, <top>, <right>, <bottom>.
PAPER	A rectangle defining the bounds of the paper, expressed in points. The format is <left>, <top>, <right>, <bottom>.
SELECTED	A comma-separated list of the names of selected objects.
UNITS	Units used to display object locations and sizes. This will be one of the following: 0 for points, 1 for inches, 2 for centimeters.

LayoutInfo returns `""` in the following situations:

winNameStr is `""` and there are no layout windows.

winNameStr is a name but there are no layout windows with that name.

itemNameStr is not "Layout" and is not the name or index of an existing object.

Examples

This example sets the background color of all selected graphs in a particular page layout to the color specified by `red`, `green`, and `blue`, which are numbers from 0 to 65535.

```
Function SetLayoutGraphsBackgroundColor(layoutName,red,green,blue)
   String layoutName      // Name of layout or "" for top layout.
   Variable red, green, blue

   Variable index
   String info
   Variable selected
   String indexStr
   String objectTypeStr
   String graphNameStr

   index = 0
   do
      sprintf indexStr, "%d", index
      info = LayoutInfo(layoutName, indexStr)
      if (strlen(info) == 0)
         break     // No more objects
      endif

      selected = NumberByKey("SELECTED", info)
      if (selected)
         objectTypeStr = StringByKey("TYPE", info)
         if (CmpStr(objectTypeStr,"Graph") == 0)// This is a graph?
            graphNameStr = StringByKey("NAME", info)
            ModifyGraph/W=$graphNameStr wbRGB=(red,green,blue)
            ModifyGraph/W=$graphNameStr gbRGB=(red,green,blue)
         endif
      endif

      index += 1
   while(1)
End
```

The **Layout** operation. See Chapter II-16, **Page Layouts**.

LayoutMarquee

LayoutMarquee

LayoutMarquee is a procedure subtype keyword that puts the name of the procedure in the layout Marquee menu. See **Marquee Menu as Input Device** on page IV-140 for details.

See Also

See Chapter II-16, **Page Layouts**.

LayoutStyle

LayoutStyle

LayoutStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Layout dialog and in the Layout Macros menu. See **Layout Style Macros** on page II-389 for details.

See Also

See Chapter II-16, **Page Layouts** and **Layout Style Macros** on page II-389.

leftx

leftx(*waveName*)

The leftx function returns the X value of point 0 (the first point) of the named 1D wave. The leftx function is not multidimensional aware. The multidimensional equivalent of this function is **DimOffset**.

Details

Point 0 contains a wave's *first* value, which is usually the leftmost point when displayed in a graph. Leftx returns the value elsewhere called *x0*. The function DimOffset returns any of x0, y0, z0, or t0, for dimensions 0, 1, 2, or 3.

See Also

The **deltax** and **rightx** functions.

For multidimensional waves, see **DimDelta**, **DimOffset**, and **DimSize**.

For an explanation of waves and X scaling, see **Changing Dimension and Data Scaling** on page II-83.

Legend

Legend [*flags*] [*legendStr*]

The Legend operation puts a legend on a graph or page layout.

Parameters

legendStr contains the text that is printed in the legend.

If *legendStr* is missing or is an empty string (""), the text needed for a default legend is automatically generated. Legends are automatically updated when waves are appended to or removed from the graph or when you rename a wave in the graph.

See **Legend Text** on page III-52 for a discussion of what *legendStr* may contain.

Flags

/H=*legendSymbolWidth*

Sets the width in points of the area in which to draw the wave symbols. A value of 0 means "default". This results in a width that is based on the text size in effect when the symbol is drawn. A value of 36 gives a 0.5 inch (36 points) width which is nice in most cases.

/H={*legendSymbolWidth*, *minThickness*, *maxThickness*}

A newer form (Igor Pro 4.0) of the /H flag. The *legendSymbolWidth* parameter works the same as described above.

The *minThickness* and *maxThickness* parameters allow you to create a legend whose line and marker thicknesses are different from the thicknesses of the associated traces in the graph. This can be handy to make the legend more readable when you use very thin lines or markers for the traces.

minThickness and *maxThickness* are values from 0.0 to 10.0. Also, setting *minThickness* to 0.0 and *maxThickness* to 0.0 (default) uses the same thicknesses for the legend symbols as for the traces.

/J

Disables the default legend mechanism so that a default legend is not created even if *legendStr* is an empty string ("") or omitted.

Window recreation macros use /J in case *legendStr* is too long to fit on the same command line as the Legend operation itself. In this case, an AppendText command appears after the Legend command to append *legendStr* to the empty legend. For really long values of *legendStr*, there may be multiple AppendText commands.

/M[=*saMeSize*]

/M or /M=1 specifies that legend markers should be the same size as the marker in the graph.

/M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.

For all other flags:

/A=*anchorCode*	/C	/E[=*exterior*]	/F=*frame*	/K
/N=*name*	/R=*newName*	/S=*style*	/T=*tabSpec*	/V=*vis*
/W=*winName*	/X=*xoffset*	/Y=*yoffset*		

see the **TextBox** and **AppendText** operations. Also see **ColorScale** and **Tag**.

Examples

The command `Legend` (with no parameters) creates a default legend. A default legend in a layout contains a line for each wave in each of the graphs in the layout, starting from the bottom graph and working toward the front.

The command:

```
Legend/C/N=name ""
```

changes the named existing legend to a default legend.

You can put a legend in a page layout with a command such as:

```
Legend "\s(Graph0.wave0) this is wave0"
```

This creates a legend in the layout that shows the symbol for wave0 in Graph0. The graph named in the command is usually in the layout but it doesn't have to be.

See Also
Legend Text on page III-52 and the **TextBox**, **Tag**, and **ColorScale** operations.

legendreA

legendreA(*n*, *m*, *x*)

The legendreA function returns the associated Legendre polynomial: $P_n^m(x)$ where n and m are integers such that $0 \le m \le n$ and $|x| \le 1$.

Arfken, G., *Mathematical Methods for Physicists*, Academic Press, New York, 1985.

limit

limit(*num*, *low*, *high*)
The limit function returns *num*, limited to the range from *low* to *high*:

num if *low* <= *num* <= *high*.

low if *num* < *low*.

high if *num* > *high*.

See Also
SelectNumber function.

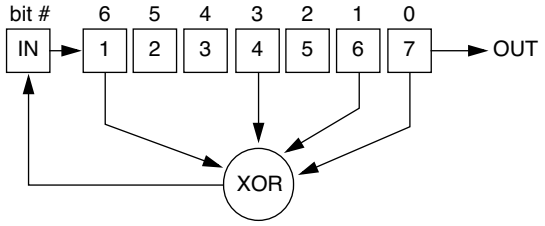
LinearFeedbackShiftRegister

LinearFeedbackShiftRegister [***flags***]
The LinearFeedbackShiftRegister operation implements a, well, linear feedback shift register, or LFSR. A LFSR is a way to produce a sequence of very bad pseudorandom numbers, or a random bit stream (that is, a random sequence of zeroes of ones that over time are nearly equal in number).

If it produces bad random numbers, why would I want to use a LFSR? A properly-configured LFSR will create a "maximal-length sequence": a LFSR of N bits will produce 2^N-1 numbers in a quasi-random sequence without repeating. That is, it will produce all the N-bit numbers except zero. This gives the sequence good spectral properties for certain applications, and, taking the least-significant bit as the output, it creates a pseudorandom bit stream with nearly equal numbers of zeroes and ones (*nearly* means one more one than zeroes).

The LinearFeedbackShiftRegister operation generates either a wave full of the sequential states of the shift register or a wave full of ones and zeroes representing the least significant bit of the shift register.

Linear Feedback Shift Registers
A LFSR is a shift register with taps. The tap bits are XOR'ed together and the result, after the register is shifted, becomes the new most significant bit. Here is a diagram of a 7-bit LFSR:



Each successive number is generated by shifting the contents of the register (boxes 1-7) to the right, while shifting in the output of the XOR node. The XOR node samples specified bits of the register contents, generating its output ready to be shifted in. Thus, the inputs of the XOR are bits sampled *before* a shift; the output of the XOR becomes the leading bit in the register *after* a shift.

In many applications the output of interest is the stream of bits that appear in the last position. This stream of bits is a pseudorandom sequence of ones and zeroes (or ones and minus ones, or whatever other binary sequence you need).

The bits fed into the XOR node are referred to as *taps*. The taps illustrated here would be specified with the tap list 7,6,4,1. As implemented in Igor Pro, the output tap (tap 7 in the illustration) is the least significant bit, so an alternate way to express the tap list is as the binary number 1001011_2 (77_{10}).

With the right taps, a LFSR produces a maximal-length sequence. The list of sequential states in a maximal-length sequence has length 2^N-1 without repeating a state. That means that every possible N-bit nonzero number appears exactly once in the maximal-length sequence.

Maximal-length tap lists always have an even number of taps.

If you have a tap list that gives a maximal-length sequence, you can generate another tap list from it. If your tap list is (n, A, B, C) the new tap list is (n, n-C, n-B, n-A). This new tap list will generate a bit stream that is the mirror image in time of the bit stream produced by the first tap list.

Flags

/DEST=*wavename* Specifies a wave to receive the generated sequence. With /MODE=0, the number type of the wave must have at least *nbits* bits for an integer wave, or at least an *nbit* mantissa if it is a floating-point wave. That is, /N=25 requires a double-precision wave or a 32-bit integer wave. /N=18 requires any floating-point wave or a 16- or 32-bit integer wave. If you use an integer wave, we recommend an unsigned integer wave for /N=8, 16, or 32.

If /MODE=1 is used, any number type is acceptable. See the Details for what happens if you don't use /DEST.

If *wavename* doesn't exist, a suitable integer wave will be made.

If *wavename* already exists, LinearFeedbackShiftRegister will use it as-is. The sequence length will be taken from the wave. If the number type of the wave is not suitable, an error is issued. If the sequence length is less than the number of points in your wave, it will be truncated to match.

/FREE In a user-defined function, makes a free wave. See **Free Waves** on page IV-71 for details.

/INIT=*initialValue* Sets the initial value of the shift register to *initialValue*. This will also be the first value in the output for /MODE=0, or the least-significant bit of *initialValue* will be the first output for /MODE=1. You can use this initial value to restart a very long sequence from the last state of a previous run.

Default is a single 1 bit in the first position (bit *nbits*-1 for /N=*nbits*).

/LEN=*length* Sets the length of sequence to generate. If the sequence repeats before *length* states are generated, the sequence is terminated early. If *length* is larger than the number of states in a maximal-length sequence, you will get a maximal-length sequence, or a shorter sequence if the initial value is seen again (that is, your sequence is not a maximal-length sequence).

You can specify *length* greater than the maximal-length sequence length, but it will be truncated to the maximal length.

/MAX=*index* An internal table of tap lists gives maximal-length sequences. This table has up to 32 tap lists for each value of *nbits*. You select a tap list by setting index to a number from 0 to 31. For values of *nbits* that do not have 32 maximal-length tap lists, the table repeats. Most *nbits* values have many more than 32 possible maximal-length sequences. For each tap list in the table, another tap list can be accessed using the /MROR flag.

/MODE=*doBitStream*

Sets the output stream format.

doBitStream=0: Succession of bit register states (default).

doBitStream=1: Stream of ones and zeroes.

/MROR [=*doMirror*] Transforms the tap list into its complementary tap list, creating a mirror-image bit stream, when you use /MROR or *doMirror*=1. Specify the tap list using /TAPS, /TAPB, or /MAX.

/N=*nbits* Determines the number of bits in the shift register. A maximal-length sequence will have 2^{nbits}-1 states. *nbits* must be in the range of 1-32. Note that *nbits* = 1 or 2 is not very interesting.

/STOP=*stopValue* Terminates the sequence when *stopValue* is the next shift register value. You can use this flag to generate long sequences using multiple calls to LinearFeedbackShiftRegister by storing the initial value of the first call, and setting *stopValue* to that initial value in subsequent calls.

/TAPB=*tapbits* An alternate way to express the tap list. *tapbits* is a number in which each bit represents a tap, with bit 0 representing the tap with tap number *nbits*.

/TAPS={*t1*, *t2*, …} Specifies the tap list. Tap numbers are in the range from 1 to *nbits*.

Details

If the /TAPS, /TAPB, or /MAX flags are absent, the maximal-length sequence corresponding to /MAX=0 is generated.

In you omit the /DEST flag, a wave named W_LFSR will be generated for you. W_LFSR is an unsigned integer wave with number type set to the minimum size for the shift register size and /MODE setting. Thus, if you set `/N=10/MODE=0`, W_LFSR will be an unsigned 16-bit integer wave.

Because W_LFSR is an unsigned integer wave, you will need to redimension the wave to a floating-point wave for many purposes. Use the **Redimension** operation or the Redimension Waves item in the Data menu.

Up to /N=18, W_LFSR will initially be created large enough to hold a maximal-length sequence, unless you request a shorter sequence using the /LEN flag. If the initial value is seen again before a maximal-length sequence is generated, it means that the tap list specified was not one that generates a maximal-length sequence, and generation is terminated. The wave is shortened to the generated sequence length.

If you set a register size greater than /N=18 and you do not use /LEN, the generated sequence will stop after 2^{18}-1 (262143) states. Note that beyond some N, it will be impossible to create a wave large enough to hold a maximal-length sequence.

Some tap lists do not generate maximal-length sequences but also do not repeat the initial value. In that case, the generated sequence will be of maximal length but will contain repeated subsequences. The V_flag variable will be set to 0 if the sequence was not a maximal-length sequence, or 1 if it was. If /LEN=*length* values were generated, V_flag is set to 2.

If you specify your own wave using /DEST, the sequence length will be the same as the length of your wave. Your wave will be resized if a shorter sequence is generated.

Generating Long Sequences in Smaller Segments

Very long maximal-length sequences will not fit in the largest wave you can make. It may also be more convenient to make multiple, small fragments of a longer sequence. You can do this using the /INIT, /STOP, and /LEN flags, along with the V_nextValue variable. Here is an example of making 1000-point subsequences from a 16-bit maximal-length sequence:

```
// Start with the first 1000 states, with initial value of 1
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=1
// Restart using the V_nextValue variable to continue the sequence
// /STOP=1 sets the stopping value to the first initial value
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_nextValue)/STOP=1
// Continue…
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_nextValue)/STOP=1
```

Variables

The LinearFeedbackShiftRegister operation returns information in the following variables:

`V_flag` Set to zero when a nonmaximal-length sequence was detected. This occurs if the initial value is seen again before a maximal-length sequence was generated, or if a maximal-length sequence was generated but the final state was not the same as the initial state.

Set to 1 when a maximal-length sequence was generated.

Set to 2 when the sequence was limited by /LEN=*length* or by the default limit of 2^{18}-1 (262143) states.

`V_tapValue` Set to the binary representation of the tap sequence used. That is, you can generate the same sequence using `/TAPB=V_tapValue`. If you use /MROR=1, V_tapValue reflects that setting. It will also give the actual tap value used when you specify the a maximal-length sequence using the /MAX flag.

`V_nextValue` Set to the next value beyond the last generated register state. This can be used to restart a truncated sequence.

Examples

Generate a 16-bit maximal-length sequence and reprocess the output values to be centered on zero and normalized to a maximum value of 1:

```
LinearFeedbackShiftRegister/N=16
Redimension/D W_LFSR
```

```
W_LFSR -= 2^15
W_LFSR /= 2^15-1
```

Another way to do the same thing that avoids the Redimension operation, which could lead to fragmentation of memory:

```
Make/D/N=(2^16-1) LFSR_output
LinearFeedbackShiftRegister/N=16/DEST=LFSR_output
LFSR_output -= 2^15
LFSR_output /= 2^15-1
```

Make a bit stream with random +1 and -1 instead of 0 and 1:

```
LinearFeedbackShiftRegister/N=16/MODE=1
Redimension/B W_LFSR
W_LFSR = W_LFSR*2-1
```

See Also

If you really need random numbers, we provide high-quality RNG's that return random deviates from a number of distributions. See **enoise**, **gnoise**, and others.

References

A discussion of LFSR's can be found in "Generation of Random Bits" (Section 7.4) in Press, William H., *et al*., *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992. They refer to "primitive polynomials modulo 2" and do not use the name Linear Feedback Shift Register, but it is the same thing. We use an implementation equivalent to their Method I.

ListBox

ListBox [**/Z**] ***ctrlName*** [***keyword = value*** [**,** ***keyword = value*** **…**]]

The ListBox operation creates or modifies the named control that displays, in the target window, a list from which the user can select any number of items.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the ListBox control to be created or changed.

The following keyword=value parameters are supported:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of `default`, `native`, or `os9`.

platform can be one of `Mac`, `Win`, or `All`.

See **Button** and **DefaultGUIControls** for more appearance details.

clickEventModifiers=*modifierSelector*

Selects modifier keys to ignore when processing clicks to start editing a cell or when toggling a checkbox. That is, use this keyword if you want to prevent a shift-click (for instance) from togging checkbox cells. Allows the action procedure to receive mousedown events with those modifiers without interfering actions on the part of the listbox control.

modifierSelector is a bit pattern with a bit for each modifier key; sum these values to get the desired combination of modifiers:

modifierSelector=1:	Control key (Ctrl)
modifierSelector=2:	Option (Macintosh) or Alt (Windows)
modifierSelector=4:	Context click (right click on Windows, control-click on Macintosh)
modifierSelector=8:	Shift key
modifierSelector=16:	Cmd (Macintosh) key
modifierSelector=32:	Caps lock key

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

col=*c*

Sets the left-most visible column (user scrolling will change this). The list is scrolled horizontally as far as possible. Sometimes this won't be far enough to

actually make column *c* the first column, but it will at least be visible. Use *c* =1 to put the left edge of column 1 (the *second* column) at the left edge of the list.

colorWave= *cw*
: Specifies a 3 column numeric wave containing red, green, and blue values as short unsigned integers. Used in conjunction with planes in selWave to define foreground and background colors for individual cells. Values range from 65535 (full on) to 0.

disable=*d*
: Sets user editability of the control.
  d=0: Normal.
  d=1: Hide.
  d=2: Draw in gray state; disable control action.

editStyle= *e*
: Sets the style for cells designated as editable (see selWave, bit 1).
  e=0: Uses a light blue background (default).
  e=1: Draws a frame around the cell with a white background.
  e=2: Combines the frame with the blue background. The background in all cases can be overridden using the colorWave parameter.

font="*fontName*"
: Sets the font used for the list box items, e.g., `font="Helvetica"`.

frame= *f*
: Specifies the list box frame style.
  f=0: No frame.
  f=1: Simple rectangle.
  f=2: 3D well.
  f=3: 3D raised.
  f=4: text well style.

fsize= s
: Sets list box font size.

fstyle=*fs*
: *fs* is a binary coded number with each bit controlling one aspect of the font style as follows:
  bit 0: Bold.
  bit 1: Italic.
  bit 2: Underline.
  bit 3: Outline (*Macintosh only*).
  bit 4: Shadow (*Macintosh only*).
  See **Setting Bit Parameters** on page IV-12 for details about bit settings.

hScroll=*h*
: Scrolls the list to the right by *h* pixels (user scrolling will change this). *h* is the total amount of horizontal scrolling, not an increment from the current scroll position: *h* will be the value returned in the V_horizScroll variable by **ControlInfo**.
  The hScroll value will not be automatically included in a ListBox recreation macro until Igor Pro 6 or later (to keep experiments compatible with Igor 5.0 and 5.01) unless you execute `SetIgorOption recreateListboxHScroll=1`. This means that normally the scroll position will be lost when saving a ListBox window recreation macro, and hScroll won't be included in the ControlInfo S_recreation string or in the WinRecreation result.

keySelectCol= *col*
: Sets scan column number *col* when doing keyboard selection. Default is to scan column zero.

listWave= *w*
: A 1D or 2D text wave containing the list contents.

mode=*m*
: List selection mode specifying how many list selections can be made at a time.
  m=0: No selection allowed.
  m=1: One or zero selection allowed.
  m=2: One and only one selection allowed.
  m=3: Multiple, but not disjoint, selections allowed.
  m=4: Multiple and disjoint selections allowed.
  When multiple columns are used, you can enable individual cells to be selected using modes 5, 6, 7, and 8 in analogy to *m*=1-4. When using *m*=3 or 4 with multiple

columns, only the first column of the selWave is used to indicate selections. Checkboxes and editing mode, however, use all cells even in modes 0-4.

Modes 9 and 10 are the same as modes 4 and 8 except they use different selection rules and require testing bit 3 as well as bit 0 in selWave. In modes 4 and 8, a shift click toggles individual cells or rows, but in modes 9 and 10, the Command (*Macintosh*) or Ctrl (*Windows*) key toggles individual cells or rows whereas Shift defines a rectangular selection. T o determine if a cell is selected, perform a bitwise AND with `0x09`.

proc= *p* — Set name of user function proc to be called upon certain events. See discussion below.

pos={*left*,*top*} — Sets the location of top left corner of the list box in pixels.

pos+={*dx*,*dy*} — Offsets the position of the list box in pixels.

row=*r* — *r* is desired top row (user scrolling will change this). Use a value of -1 to scroll to the first selected cell (if any). Combine with selRow to select a row and to ensure it is visible (modes 1 and 2).

selCol= *c* — Defines the selected column when mode is 5 or 6 and no selWave is used. To read this value, use **ControlInfo** and the V_selCol variable.

selRow= *s* — Defines the selected row when mode is 1 or 2; when no selWave is used, it is defined by modes 5 or 6. Use -1 for no selection.

To read this value, use **ControlInfo** and the V_value variable.

selWave= *sw* — *sw* is a numeric wave with the same dimensions as listWave. It is optional for modes 0-2, 5 and 6 and required in all other modes.

In modes greater than 2, *sw* indicates which cells are selected. In modes 1 and 2 use **ControlInfo** to find out which row is selected.

In all modes *sw* defines which cells are editable or function as checkboxes or disclosure controls.

Numeric values are treated as integers with individual bits defined as follows:

Bit 0 (0x01): Cell is selected.

Bit 1 (0x02): Cell is editable.

Bit 2 (0x04): Cell editing requires a double click.

Bit 3 (0x08): Current shift selection.

Bit 4 (0x10): Current state of a checkbox cell.

Bit 5 (0x20): Cell is a checkbox.

Bit 6 (0x40): Cell is a disclosure cell. Drawn as a disclosure triangle (*Macintosh*) or a treeview expansion node (*Windows*).

In modes 3 and 4 bit 0 is set only in column zero of a multicolumn listbox.

Other bits are reserved. Additional dimensions are used for color info. See the discussion for colorWave. As of Igor Pro 6, selWave is not required for modes 5 and 6.

`setEditCell={`*`row`*`,`*`col`*`,`*`selStart`*`,`*`selEnd`*`}`

Initiates edit mode for the cell at *row*, *col*. An error is reported if *row* or *col* is less than zero. Nothing happens and no error is reported if *row*, *col* is beyond the limits of the listbox, or if the cell has not been made editable by setting bit 1 of *selWave*.

selStart and *selEnd* set the range of characters that are selected when editing is initiated; 0 is the start of the text. If there are N characters in the listbox cell, setting *selStart* or *selEnd* to N or greater moves the start or end of the selection to the point after the last character. Setting *selStart* and *selEnd* to the same value selects no characters and the insertion point is set to *selStart*. Setting *selStart* to -1 always causes all characters to be selected.

size={*width*,*height*} — Sets list box size in pixels.

special={*kind*,*height*,*style*}

Specifies special cell formatting or contents.

kind=0: Normal text but with specified *height* (if nonzero). Use a *style* of 1 to autocalculate widths based on the entire list contents. In this case, user widths are taken to be minimums and the last is not repeated.

kind=1: Text taken to be the names of graphs or tables. Images of the graphs or tables are displayed in the cells. Use a *style* of 0 to display just the presentation portion of the graph or 1 to display it entirely. For tables, only the presentation portion is displayed.

kind=2: Text taken to be the names of pictures. Images are displayed in the cells.

kind=3: Displays a PNG, TIFF, or JPEG image. You can obtain binary picture data using SavePict.

For *kind*=1 or 2, *height* may be zero to auto-set cell height to same as width or a specific value.

titleWave=*w* Specifies a text wave containing titles for the listbox columns, instead of using the list wave dimension labels. Each row is the title for one column; if you have N columns you must have a wave with N rows. Allows more than 31 characters for a title, which is particularly important if you use styled text.

userColumnResize= *u* Enables resizing the list columns using the mouse.

u =0: Columns are not resizable (default). The widths parameter still works, though.

u =1: User can resize columns by dragging the column dividers.

When resizing a column without Option, Alt, or Shift modifiers (a "normal" resizing), any width added to the column is subtracted from the following column (if any).

When resizing while pressing Option (*Macintosh*) or Alt (*Windows*), only columns following the dragged divider will move (the same way table columns are resized).

When pressing Shift, all columns are set to the same width as the column being resized. If the total widths of all columns is less than the width of the listbox, then each column expands to fill the available width.

userdata=*UDStr* Sets the unnamed user data to *UDStr*.

userdata(*UDName*)=*UDStr*
Sets the named user data, *UDName*, to *UDStr*.

userdata+=*UDStr* Appends *UDStr* to the current unnamed user data.

userdata(*UDName*)+=*UDStr*
Appends *UDStr* to the current named user data, *UDName*.

widths={*w1*,*w2*,…} Optional list of minimum column widths in screen pixels. If more columns than widths, the last is repeated. If total of widths is greater than list box width then a horizontal scroll bar will appear. If total is less than available width then each expands proportionally.

widths+={*w1*,*w2*,…} Additional column widths. Because only 400 characters fit on a command line, lists with many columns may require multiple widths+= parameters to define all the column widths. However if all the widths are the same, widths+= is not needed; just use:

```
ListBox ctrlName widths={sameWidth}
```

win=*winName* Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-95 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

If the list wave has column dimension labels (see **SetDimLabel**), then those will be used as column titles. Note that a 1D wave is subtly different from a 1 column 2D wave. The former does not have any columns and therefore no column dimension labels.

Alternately, use a text wave with the titleWave keyword to specify column titles.

You can make a column title bold using TextBox-style escape codes. For instance, to make a title bold use the \f01 escape sequence:

```
SetDimLabel 1, columnNum, $"\\f01My Label", textWave
```

If you can't fit title text within the 31 character limit (styled text can be especially long), use the titleWave keyword with a text wave. The wave must have as many rows as the list wave has columns. When using a title wave, there are no restrictions on the number of or what characters you can use.

This example uses a title wave to add a red up-arrow graph marker to the end of a centered title:

```
Make/O/T/N=(numColumns) columnTitles
columnTitles[colNum]="\\JCThis is the title\\K(65535,0,0)\\k(65535,0,0)\\W523"
ListBox list0 titleWave=columnTitles
```

That's a 51-character title that results in 19 characters or symbols that you actually see. \JC requests centered text, \K sets the text color (which colors the inside of the graph marker), \k sets the marker stroke color, and \W523 inserts a down-pointing triangular graph marker.

When using modes that allow multiple selections, use Shift to extend or add to the selection.

You can specify individual cells as being editable by setting bit 1 (counting from zero on the right) in selWave. The user can start editing a cell by either clicking in it or, if the cell is selected, by pressing Enter (or Return). When finished, the user can press Enter to accept the changes or can press Escape to reject changes. The user may also press Up or Down Arrow to accept changes and begin editing the next editable cell in a column. Likewise, Tab and Shift-Tab moves to the next or previous column in a row. If bit 2 of selWave is set then a double click will be required rather than a single click. **Note**: in edit mode, Tab and Shift-Tab are used to move left and right because the Left and Right Arrow keys are used to move the text entry cursor left and right.

When the listbox has keyboard focus (either by tabbing to the list box or by clicking in the box), the keyboard arrow keys move a cell selection (or row depending on mode). When not in cell edit mode, Tab and Shift-Tab move the keyboard focus to other objects in the window. The Home, End, Page Up, and Page Down keys affect the vertical scroll bar.

When the listbox has focus, the user may type the first few chars of an entry in the list to select that entry. Only the first column is used. If a match is not found then nothing is done. The search is case insensitive.

You may define a user-function that will be called when certain events occur. Your action function must have the following syntax:

```
Function MyListboxProc(ctrlName,row,col,event) : ListboxControl
   String ctrlName     // name of this control
   Variable row        // row if click in interior, -1 if click in title
   Variable col        // column number
   Variable event      // event code
   …
   return 0            // other return values reserved
End
```

The "`: ListboxControl`" designation tells Igor to include this procedure in the Procedure pop-up menu in the List Box Control dialog.

The action procedure for a ListBox control can also use a predefined structure `WMListboxAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a ListBox control, otherwise it will use the old-style method.

A ListBox action procedure using a structure has the format:

```
Function newActionProcName(LB_Struct) : ListboxControl
   STRUCT WMListboxAction &LB_Struct
   …
End
```

For a ListBox control, the `WMListboxAction` structure has members as described in the following table:

`WMListboxAction` Structure Members

Member	Description
`char ctrlName[MAX_OBJ_NAME+1]`	Control name.
`char win[MAX_WIN_PATH+1]`	Host (sub)window.
`STRUCT Rect winRect`	Local coordinates of host window.

WMListboxAction Structure Members

Member	Description
STRUCT Rect ctrlRect	Enclosing rectangle of the control.
STRUCT Point mouseLoc	Mouse location.
Int32 eventCode	Event that caused the procedure to execute. See table following for eventCode values.
String userData	Primary (unnamed) user data. If this changes, it is written back automatically.
Int32 blockReentry	Prevents reentry of control action procedure. See **Control Structure blockReentry Field** on page III-386.
Int32 eventCode2	Used for the second event when two events happen at the same time. In this case, the various values in the structure refer to this second event. As of Igor 5.02, an event queue is used to deliver events to new-style action procedures and eventCode2 is not used. Instead your procedure simply gets called multiple times. See **Event Queue** on page V-343 for more details
Int32 eventMod	Bitfield of modifiers. See **Control Structure eventMod Field** on page III-385.
Int32 row, col	Row number of selection in interior or -1 if in title area, and column number of selection. The meanings of row and col are different for eventCodes 8-11:

Code	row	col
8	top visible row	horiz shift in pixels.
9	top visible row	horiz shift (user scroll).
9	-1	horiz shift (hScroll keyword).
10	top visible row	-1 (row keyword).
10	-1	first visible col (col keyword).
11	column shift	column resized by user.

	If eventCode is 11, row is the horizontal shift in pixels of the column col that was resized, not the total horizontal shift of the list as reported in V_horizScroll by ControlInfo. If row is negative, the divider was moved to the left. col=0 corresponds to adjusting the divider on the right side of the first column. Use **ControlInfo** to get a list of all column widths.
WAVE/T listWave	List wave specified by ListBox command.
WAVE selWave	Selection wave specified by ListBox command.
WAVE colorWave	Color wave specified by ListBox command.
WAVE/T titleWave	Title wave specified by ListBox command

The event code passed to your action procedure has the following meanings:

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

eventCode	Meaning
-1	Control being killed.
1	Mouse down.
2	Mouse up.
3	Double click.
4	Cell selection (mouse or arrow keys).
5	Cell selection plus Shift key.
6	Begin edit.
7	Finish edit.
8	Vertical scroll. See **Scroll Event Warnings** on page V-343.
9	Horizontal scroll by user or by the hScroll=*h* keyword.
10	Top row set by row=*r* or first column set by col=*c* keywords.
11	Column divider resized.
12	Keystroke, character code is place in row field.
13	Checkbox was clicked. This event is sent after selWave has been updated by Igor Pro 6.20 or later.

Some events cause another event immediately. For example a cell selection usually follows a mouse down. Before Igor Pro 5.02, the second event is stored in eventCode 2. In Igor Pro 5.02 and later, each event causes a separate call to your event handler. See **Event Queue** for more details.

The background and foreground (text) color of individual cells may be defined by providing colorWave in conjunction with specific planes in selWave. The planes in selWave are taken to be integer indexes into colorWave. The planes are defined by specific dimension labels and not by specific plane numbers. To provide foreground colors, define a plane labeled "foreColors" that contains the desired index values. Likewise define and fill a plane labeled "backColors" for background colors. The value 0 is special and indicates that the default colors should be used. Note that if you have a one column list for which you want to supply colors, the selWave needs to be three dimensional but with just one column. Here is an example:

```
Make/T/N=(5,1) tw= "row "+num2str(p)        // 5 row, 1 col text wave (2D)
Make/B/U/N=(5,1,2) sw                       // 5 row, 1 col, 2 plane byte wave
Make/O/W/U myColors={{0,0,0},{65535,0,0},{0,65535,0},{0,0,65535},{0,65535,65535}}
MatrixTranspose myColors      // above was easier to enter as 3 rows, 5 cols

NewPanel
ListBox lb,mode=3,listWave= tw,selWave= sw,size={200,100},colorWave=myColors
sw[][][1]= p                          // arbitrary index values into plane 1
```

Now, execute the following commands one at a time and observe the results:

```
SetDimLabel 2,1,backColors,sw        // define plane 1 as background colors

SetDimLabel 2,1,foreColors,sw        // redefine plane 1 s foreground colors

sw[][][%foreColors]= 4-p             // change the color index values
```

In the above example, the selWave was defined as unsigned byte. If you need more than 254 colors, you will have to use a larger number size.

Checkboxes in Cells

You can cause a cell to contain a checkbox by setting bit 5 in selWave. The title (if any) is taken from listWave and the results (selected/deselected) is bit 4 of selWave. If a checkbox cell is selected then the space bar will toggle the checkbox. (Clicking a checkbox cell does not select it — use the arrow keys.)

Errors

Your listbox may be drawn with a red X and an error code. The error codes are:

Error	Meaning
E1	Too small.
E2	listWave is invalid (missing, not text or no rows).
E3	listWave and selWave do not match in dimensions.
E4	mode > 2 with no selWave.

Event Queue

It is possible for a single user action to produce more than one event. For instance, using the Up Arrow key while editing to select a cell that is not visible will generate events 4, 8, and 6. As of Igor 5.02, such a cascade of events will generate three separate calls to your new-style action procedure that uses a structure for input. Before Igor 5.02 eventCode2 was used to deliver a second event to your action procedure (scroll events 8, 9, and 10 were not available then).

If your code tests for a nonzero value in eventCode2, and uses it only if it is nonzero, then the event queue method will not break your code. If you have determined empirically when you need to use eventCode2 and you do not test, your code will break.

Scroll Event Warnings

Events 8, 9, and 10 report to you that the listbox has been scrolled vertically or horizontally. These events are envisioned as allowing you to keep two listboxes synchronized (you may find other uses for these events). You might use an action procedure like this one to keep two listboxes (named list0 and list1) in sync:

```
Function ListBoxProc2(LB_Struct) : ListBoxControl
   STRUCT WMListboxAction &LB_Struct

   if (LB_Struct.eventCode == 8)
      String listname
      if (CmpStr(LB_Struct.ctrlName, "list1") == 0)
         listname = "list0"
      else
         listname = "list1"
      endif
      ControlInfo $listname
      if (V_startRow != LB_Struct.row)
         listbox $listname,row=LB_Struct.row
         ControlUpdate $listname
      endif
   endif
End
```

It is very easy to create an infinite cascade of events feeding back between the two listboxes, especially if you use event 10. When this happens, you will see your listboxes jigging up and down endlessly. The test using ControlInfo is intended to make this unlikely.

The slow response of the old-style, nonstructure action procedure can defeat the ControlInfo test by delaying the action procedure execution. If you use events 8, 9, or 10, we recommended that you use the new-style action procedure.

Examples

Here is a simple Listbox example:

```
Make/O/T/N=30 tjack="this is row "+num2str(p)
Make/O/B/N=30 sjack=0
NewPanel /W=(19,61,319,261)
ListBox lb1,pos={42,9},size={137,94},listWave=tjack,selWave=sjack,mode= 3
Edit/W=(367,61,724,306) tjack,sjack
ModifyTable width(tjack)=148
```

Make selections in the list and note changes in the table and vice versa. Edit one of the list text values in the table and note update of the list.

Here is an example using a titleWave and styled text in the title cells. Note that the last title isn't very long when rendered, but requires a 63 character specification.

```
Make/O/T/N=(4,3) ListWave="row "+num2str(p)+" col "+num2str(q)
Make/O/T/N=3 titles                    // three rows to match 3-column ListWave
titles[0] = "\f01Bold Title"
titles[1] = "title with semicolon;"
titles[2] = "Marker in Gray: \K(40000,40000,40000)\k(40000,40000,40000)\W517"
```

```
NewPanel /W=(515,542,1011,794)
ListBox list0,pos={1,2},size={391,120},listWave=ListWave
ListBox list0,titleWave=titles
```

An example experiment that lets you easily experiment with ListBox settings is available in "Examples:Testing & Misc:ListBox Demo.pxp".

Setting Bit Parameters on page IV-12 for further details about bit settings.

The **GetUserData** operation for retrieving named user data.

ListMatch

ListMatch(*listStr*, *matchStr* [, *listSepStr*])

The ListMatch function returns each list item in *listStr* that matches *matchStr*.

ListStr should contain items separated by the *listSepStr* character, such as "abc;def;".

You may include asterisks in *matchStr* as a wildcard character. Note that matching is case-insensitive. See **stringmatch** for wildcard details.

ListSepStr is optional. If missing, it is taken to be ";".

See Also

The **GrepList**, **stringmatch**, **StringFromList**, and **WhichListItem** functions.

ln

ln(*num*)

The ln function returns the natural logarithm of *num*, -INF if *num* is 0, or NaN if *num* is less than 0. In complex expressions, *num* is complex, and ln(*num*) returns a complex value.

To compute a logarithm base n use the formula:

$$\log_n(x) = \frac{\log(x)}{\log(n)}.$$

See Also

The **log** function.

LoadData

LoadData [*flags*] *fileOrFolderNameStr*

The LoadData operation loads data from the named file or folder. "Data" means Igor waves, numeric and string variables and data folders containing them. The specified file or folder must be an Igor packed experiment file or a folder containing Igor binary data, such as an Igor unpacked experiment folder or a folder in which you have stored Igor binary wave files.

LoadData loads data objects into memory and they become part of the current Igor experiment, disassociated from the file from which they were loaded.

If loading from a file-system folder, the data (waves, variables, strings) in the folder, including any subfolders if /R is specified, is loaded into the current Igor data folder.

If loading from a packed Igor experiment file, the data in the file, including any packed subdata folders if /R is specified, is loaded into the current Igor data folder.

Use LoadData to load experiment data using Igor procedures. To load experiment data interactively, use the Data Browser (Data menu).

Parameters

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-398 for details on forming the path.

If *fileOrFolderNameStr* is omitted you get to locate the file (if /D is omitted) or the folder (if /D is present) via a dialog.

Flags

/D — If present, loads from a file-system folder (a directory). If omitted, LoadData loads from an Igor packed experiment file.

/I — Interactive. Forces LoadData to present a dialog.

/J=*objectNamesStr* — Loads only the objects named in the semicolon-separated list of object names.

/L=*loadFlags* — Controls what kind of data objects are loaded with a bit for each data type:

loadFlags	Bit Number	Loads this Object Type
1	0	Waves
2	1	Numeric Variables
4	2	String Variables

To load multiple data types, sum the values shown in the table. For example, /L=1 loads waves only, /L=2 loads numeric variables only, and /L=3 loads both waves and numeric variables. See **Setting Bit Parameters** on page IV-12 for further details about bit settings.

If no /L is specified, all object types are loaded. This is equivalent to /L=7. All other bits are reserved and should be set to zero.

/O[=*overwriteMode*] — If /O alone is used, overwrites existing data objects in case of a name conflict.

overwriteMode is defined as follows:

0: No overwrite, as if there were no /O.

1: Normal overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory. Incoming data folders completely replace any conflicting data folders in memory.

2: Mix-in overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory but nonconflicting objects in memory are left untouched.

See **Details** for more about overwriting.

/P=*pathName* — Specifies folder to look in for the specified file or folder. *pathName* is the name of an existing symbolic path.

/Q — Suppresses the normal messages in the history area.

/R — Recursively loads subdata folders.

/S=*subDataFolderStr* — Specifies a subdata folder within a packed experiment file to be loaded. See **Details** for more.

/T[=*topLevelName*] — If /T=*topLevelName* is specified, it creates a new data folder in the current data folder with the specified name and places the loaded data in the new data folder.

If just /T is specified, it creates a new data folder in the current data folder with a name derived from the name of the unpacked experiment folder, packed experiment file or packed subdata folder being loaded.

Details

If /T is present, LoadData loads the top level data folder and its contents. If /T is omitted, it loads just the contents of the top level data folder and not the data folder itself. This distinction has an analogy in the desktop. You can drag the contents of disk folder A into folder B or you can drag folder A itself into folder B.

If present, /S=*subDataFolderStr* specifies the subdata folder within the packed experiment file from which the load is to start. For example:

```
LoadData/P=Path1/S="Folder A:Folder B" "aPackedExpFile"
```

This starts loading from data folder “Folder B” which is in “Folder A” in the packed experiment file. Note that the string specified by /S must specify each subdata folder until the desired data folder is reached. Since this parameter is specified as a string, you must not use single quotes.

/S has no effect if you are loading from a file system folder rather than from a packed experiment file.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "`hd:Folder1:`" or "`C:\\Folder1\\`". See **Symbolic Paths** on page II-34 for details.

If /J=*objectNamesStr* is used, then only the objects named in *objectNamesStr* are loaded into the current experiment. For example, `/J="wave0;wave1"` will load only the two named waves, ignoring any other data in the file or folder being loaded.

Assume that you have an experiment that contains 5 runs where each run, stored in a separate data folder in a packed experiment file, consists of data acquired from four channels from an ADC card. Using the /J flag, you can load just one specific channel from each run. This way you can compare that channel's data from all runs without loading the other channels.

The list of object names used with /J must be semicolon-separated. A semicolon after the last object name in the list is optional. Because the object names exist in a string expression, they should not be quoted. The list is limited to 1000 characters.

Using `/J=""` acts like no /J at all.

If you load a hierarchy of data folders (using the /R flag) with /J in effect, LoadData will create each data folder in the hierarchy even if it contains none of the named objects. This behavior is necessary to avoid loading a subdata folder without loading its parent, as well as other such complications.

If you do a load of a data folder, overwriting an existing data folder of the same name, the behavior of LoadData depends on whether you use /J. If you do not use /J, the entire data folder and all of its contents are replaced. If you do use /J, just the specified objects in the data folder are replaced, leaving any other preexisting objects in the data folder unchanged.

If you do not use the /O (overwrite) flag or if you use /O=0 and there is a conflict between objects or data folders in the current data folder and objects or data folders in the file or folder being loaded, LoadData will present a dialog to ask you if you want to replace the existing data. However, LoadData can not replace an object with an object of a different type and will refuse to do so.

You can overwrite an object that is in use, such as a wave that is displayed in a graph or table. You can also overwrite a data folder that contains objects that are in use. This is a powerful feature. Imagine that you define a data structure consisting of waves, variables and possibly subdata folders. You can display the data in graphs and tables and you can display these in a layout. You can then overwrite the data with an analogous data structure from a packed experiment file and Igor will automatically update any graphs, tables, or layouts that need to be updated.

Because LoadData can load from a complex packed Igor experiment file or from a complex hierarchy of file-system folders, it does not set the variables normally set by a file loader: S_path, S_fileName, and S_waveNames. The variable V_flag is set to the total number of objects loaded, or to -1 if the user cancelled the open file dialog. To find what objects were created by LoadData, you can use the **CountObjects** and **GetIndexedObjName** functions.

See Also

The **SaveData** operation. Chapter II-9, **Importing and Exporting Data**; **Data Browser** on page II-130.

LoadPackagePreferences

LoadPackagePreferences [**/MIS=***mismatch* **/P=***pathName*] ***packageName, prefsFileName, recordID, prefsStruct***

The LoadPackagePreferences operation loads preference data previously stored on disk by the **SavePackagePreferences** operation. The data is loaded into the specified structure.

If the /P flag is present then the location on disk of the preference file is determined by *pathName* and *prefsFileName*. However in the usual case the /P flag will be omitted and the preference file is located in a file named *prefsFileName* in a directory named *packageName* in the Packages directory in Igor's preferences directory.

Note: You must choose a very distinctive name for *packageName* as this is the only thing preventing collisions between your package and someone else's package.

See **Saving Package Preferences** on page IV-226 for background information and examples.

Parameters

packageName is the name of your package of Igor procedures. It is limited to 31 characters and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else's package.

prefsFileName is the name of a preference file to be loaded by LoadPackagePreferences. It should include an extension, typically ".bin".

prefsStruct is the structure into which data from disk, if it exists, will be loaded.

recordID is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct *recordID*s to identify which structure you want to load. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the *recordID*.

Flags

/MIS=*mismatch* Controls what happens if the number of bytes in the file does not match the size of the structure:

0: Returns an error. Default behavior if /MIS is omitted.

1: Returns the smaller of the size of the structure and the number of bytes in the file. Does not return an error. Use this if you want to read and update old versions of a preferences structure.

/P=*pathName* Specifies the directory to look in for the file specified by *prefsFileName*.

pathName is the name of an existing symbolic path. See **Symbolic Paths** on page II-34 for details.

`/P=$<empty string variable>` acts as if the /P flag were omitted.

Details

LoadPackagePreferences sets the following output variables:

`V_flag` Set to 0 if no error occurred or to a nonzero error code.

If the preference file does not exist, V_flag is set to zero so you must use V_bytesRead to detect that case.

`V_bytesRead` Set to the number of bytes read from the file. This will be zero if the preference file does not exist.

`V_structSize` Set to the size in bytes of *prefsStruct*. This may be useful in handling structure version changes.

After calling LoadPackagePreferences if V_flag is nonzero or V_bytesRead is zero then you need to create default preferences as illustrated by the example referenced below.

V_bytesRead, in conjunction with the /MIS flag, makes it possible to check for and deal with old versions of a preferences structure as it loads the version field (typically the first field) of an older or newer version structure. However in most cases it is sufficient to omit the /MIS flag and treat incompatible preference data the same as missing preference data.

Example

See the example under **Saving Package Preferences in a Special-Format Binary File** on page IV-226.

See Also

SavePackagePreferences.

LoadPICT

LoadPICT [***flags***] [***fileNameStr***][**, *pictName***]

The LoadPICT operation loads a picture from a file or from the Clipboard into Igor. Once you have loaded a picture, you can append it to graphs and page layouts.

Parameters

The file to be loaded is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-398 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter.

If *fileNameStr* is "Clipboard" and /P=*pathName* is omitted, LoadPICT loads its data from the Clipboard rather than from a file.

pictName is the name that you want to give to the newly loaded picture. You can refer to the picture by its name to append it to graphs and page layouts. LoadPICT generates an error if the name conflicts with some other type of object (e.g., wave or variable) or if the name conflicts with a built-in name (e.g., the name of an operation or function).

If you omit *pictName*, LoadPICT automatically names the picture as explained in **Details**.

Flags

/I=*resIndex*	Specifies the resource to load by resource index, starting from 1 (*Macintosh only*).
/M=*promptStr*	Specifies a prompt to use if LoadPICT needs to put up a dialog to find the file.
/N=*resNameStr*	A string that specifies the resource to load by resource name (*Macintosh only*).
/O	Overwrites an existing picture with the same name. If /O is omitted and there is an existing picture with the same name, LoadPICT displays a dialog in which you can resolve the name conflict.
/P=*pathName*	Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.
/Q	Quiet: suppresses the insertion of picture info into the history area.
/R=*resourceID*	Specifies the resource to load by resource ID (*Macintosh only*).
/Z	Doesn't load the picture, just checks for its existence.

Details

If the picture file is not fully specified then LoadPICT presents a dialog from which you can select the file. "Fully specified" means that LoadPICT can determine the name of the file (from the *fileNameStr* parameter) and the folder containing the file (from the flag /P=*pathName* flag or from the *fileNameStr* parameter). If you want to force a dialog, omit the *fileNameStr* parameter.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "`hd:Folder1:`" or "`C:\\Folder1\\`". See **Symbolic Paths** on page II-34 for details.

On Macintosh, LoadPICT can load picture data from the file's data or resource fork. Most graphics programs store a picture in the data fork. Some programs may store one or more pictures as resources. If you use /R, /I, or /N, it loads the picture from the specified resource in the file. Otherwise, it loads the picture from the file's data fork.

If you omit *pictName*, LoadPICT automatically names the picture as follows:

On Macintosh, if the picture was loaded from the resource fork of a file (you used /R, /I, or /N) and the resource had a nonempty name, it uses the resource name. If necessary, the name is made legal by replacing illegal characters or shortening it.

If the picture was loaded from a file, LoadPICT uses the file name. If necessary, it makes it into a legal name by replacing illegal characters or shortening it.

Otherwise, LoadPICT uses a name of the form "PICT_*n*".

If the resulting name is in conflict with an existing picture name, Igor puts up a name conflict resolution dialog.

LoadPICT sets the variable V_flag to 1 if the picture exists and fits in available memory or to 0 otherwise.

It also sets the string variable S_info to a semicolon-separated list of values:

Keyword	Information Following Keyword
NAME	Name of the loaded PICT, often "PICT_0", etc.
SOURCE	One of "data fork", "resource fork" or "Clipboard".
RESOURCENAME	Name of the resource the picture was loaded from, or `""` if the source was not the file's resource fork.
RESOURCEID	Resource ID the picture was loaded from, or 0 if the source was not the file's resource fork.
TYPE	One of: "Enhanced metafile", "Windows metafile", "DIB", "Windows bitmap", "PICT", "PNG", or "Unknown type".

Keyword	Information Following Keyword
BYTES	Amount of memory used by the picture.
WIDTH	Width of the picture in pixels.
HEIGHT	Height of the picture in pixels.
PHYSWIDTH	Physical width of the picture in points.
PHYSHEIGHT	Physical height of the picture in points.

LoadWave

LoadWave [***flags***] [***fileNameStr***]

The LoadWave operation loads data from the named Igor binary, Igor text, delimited text, fixed field text, or general text file into waves. LoadWave can load 1D and 2D data from delimited text, fixed field text and general text files, or data of any dimensionality from Igor binary and Igor text files.

Parameters

The file to be loaded is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If LoadWave can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-398 for details on forming the path.

If *fileNameStr* is "Clipboard" and /P=*pathName* is omitted, LoadWave takes its data from the Clipboard rather than from a file. This is not implemented for binary loads.

If *fileNameStr* is omitted you get to locate the file via a dialog.

Flags

/A "Auto-name and go" option (used with /G, /F or /J).

This skips the dialog in which you normally enter wave names. Instead it automatically assigns names of the form *wave*0, *wave*1, choosing names that are not already in use. When used with /W, it reads wave names from the file instead of automatically assigning names and /A just skips the wave name dialog. The /B flag can also override names specified by /A.

/A=*baseName* Same as /A but it automatically assigns wave names of the form *baseName*0, *baseName*1.

/B=*columnInfoStr* Specifies the name, format, numeric type, and field width for columns in the file. See **Specifying Characteristics of Individual Columns**.

/C This is used in experiment recreation commands generated by Igor to force experiment recreation to continue if an error occurs in loading a wave.

/D Creates double precision waves. (Used with /G, /F or /J.) The /B flag can override the numeric precision specified by the /D flag.

/E=*editCmd*

editCmd= 1: Makes a new table containing the loaded waves.

editCmd= 2: Appends the loaded waves to the top table. If no table exists, a new table is created.

editCmd= 0: Same as if /E had not been specified (loaded waves are not put in any table).

/F={*numColumns*, *defaultFieldWidth*, *flags*}

Indicates that the file uses the fixed field file format. Most FORTRAN programs generate files in this format.

numColumns is the number of columns of data in the file.

defaultFieldWidth is the default number of characters in each column. If the columns do not all have the same number of characters, you need to use the /B flag to provide more information to LoadWave.

flags is a bitwise parameter that controls the conversion of text to values. The bits are defined as follows:

bit 0: If set, any field that consists entirely of the digit "9" is taken to be blank. A field that consists entirely of the digit "9" except for a leading "+" or "-" is also taken to be blank.

All other bits are reserved and you should use 0 for them.

/G Indicates that the file uses the general text format.

/H Loads the wave into the current experiment and severs the connection between the wave and the file. When the experiment is saved, the wave copy will be saved as part of the experiment. For a packed experiment this means it is saved in the packed experiment file. For an unpacked experiment this means it is saved in the experiment's home folder.

See **Sharing Versus Copying Igor Binary Files** on page II-165.

/J Indicates that the file uses the delimited text format.

/K=*k* Controls how to determine whether a column in the file is numeric or text (only for delimited text and fixed field text files).

k=0: Deduces the nature of the column automatically.

k=1: Treats all columns as numeric.

k=2: Treats all columns as text.

This flag as well as the ability to load text data into text waves were added in Igor Pro 3.0. The default for the LoadWave operation is /K=1, meaning that it will treat all columns as numeric. We did this so that existing procedures would behave the same in Igor Pro 3.0 as before. Use /K=0 when you want to load text columns into text waves. /K=2 may have use in a text-processing application.

For finer control, the /B flag specifies the format of each column in the file individually.

/L={*nameLine*, *firstLine*, *numLines*, *firstColumn*, *numColumns*}

Affects loading delimited text, fixed field text, and general text files only (/J, /F or /G). /L is accepted no matter what the load type but is ignored for Igor binary and Igor text loads. Line and column numbers start from 0.

nameLine is the number of the line containing column names. For general text loads, 0 means auto. See **Loading General Text Files** on page II-153 for details.

firstLine is the number of the first line to load into a wave. For general text loads, 0 means auto. See **Loading General Text Files** on page II-153 for details.

numLines is the number of lines that should be treated as data. 0 means auto which loads until the end of the file or until the end of the block of data in general text files. The *numLines* parameter can also be used to make loading very large files more efficient. See **Loading Very Large Files**.

firstColumn is the number of the first column to load into a wave. This is useful for skipping columns.

numColumns is the number of columns to load into a wave. 0 means auto, which loads all columns.

/M Loads data as matrix wave. If /M is used then it ignores the /W flag (read wave names) and follows the /U flags instead.

The wave is autonamed unless you provide a specific wave name using the /B flag.

The type of the wave (numeric or text) is determined by an assessment of the type of the first loaded column unless you override this using the /K flag or the /B flag.

See **The Load Waves Dialog for Delimited Text — 2D** on page II-149 for further information.

/N Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.

/N=*baseName* Same as /N except that it automatically assigns wave names of the form *baseName0*, *baseName1*.

/O Overwrite existing waves in case of a name conflict.

/P=*pathName* Specifies the folder to look in for *fileNameStr*. *pathName* is the name of an existing symbolic path.

/Q Suppresses the normal messages in the history area.

/R={*languageName*, *yearFormat*, *monthFormat*, *dayOfMonthFormat*, *dayOfWeekFormat*, *layoutStr*, *pivotYear*}
Specifies a custom date format for dates in the file. If the /R flag is used, it overrides the date setting that is part of the /V flag.

languageName controls the language used for the alphabetic date components, namely the month and the day-of-week. *languageName* is one of the following:

Default			
Chinese	ChineseSimplified	Danish	Dutch
English	Finnish	French	German
Italian	Japanese	Korean	Norwegian
Portuguese	Russian	Spanish	Swedish

Default means the system language on Macintosh or the user default language on Windows.

yearFormat is one of the following codes:

1: Two digit year.

2: Four digit year.

monthFormat is one of the following codes:

1: Numeric, no leading zero.

2: Numeric with leading zero.

3: Abbreviated alphabetic (e.g., Jan).

4: Full alphabetic (e.g., January).

dayOfMonthFormat is one of the following codes:

1: Numeric, no leading zero.

2: Numeric with leading zero.

dayOfWeekFormat is one of the following codes:

1: Abbreviated alphabetic (e.g., Mon).

2: Full alphabetic (e.g., Monday).

layoutStr describes which components appear in the date in what order and what separators are used. *layoutStr* is constructed as follows (but with no line break):

```
"<component keyword><separator>
<component keyword><separator>
<component keyword><separator>
<component keyword>"
```

where <component keyword> is one of the following:

```
Year
Month
DayOfMonth
DayOfWeek
```

and <separator> is a string of zero to 15 characters.

Starting from the end, parts of the layout string must be omitted if they are not used.

Extraneous spaces are not allowed in *layoutStr*. Each separator must be no longer than 15 characters. No component can be used more than once. Some components may be used zero times.

pivotYear determines how LoadWave interprets two-digit years. If the year is specified using two digits, yy, and is less than *pivotYear* then the date is assumed to be 20yy. If the two digit year is greater than or equal to *pivotYear* then the year is assumed to be 19yy. *pivotYear* must be between 4 and 40.

See **Loading Custom Date Formats** for further discussion of date formats.

/T Indicates that the file uses the Igor text format.

Although LoadWave is generally thread-safe, it is not thread-safe to load an Igor text file containing an Igor command (e.g., "X <command>").

/U={*readRowLabels*, *rowPositionAction*, *readColLabels*, *colPositionAction*}

These parameters affect loading a matrix (/M) from a delimited text (/J) or a fixed field text (/F) file. They are accepted no matter what the load type is but are ignored when they don't apply.

If *readRowLabels* is nonzero, it reads the first column of data in the file as the row labels for the matrix wave.

rowPositionAction has one of the following values:

0: The file has no row position column.

1: Uses the row position column to set the row scaling of the matrix wave.

2: Creates a 1D wave containing the values in the row position column. The name of the 1D wave will be the same as the matrix wave but with the suffix "_RP".

The *readColumnLabels* and *columnPositionAction* parameters have analogous meanings. The suffix used for the column position wave is "_CP".

See Chapter II-9, **Importing and Exporting Data** for further details.

/V={*delimsStr*, *skipCharsStr*, *numConversionFlags*, *loadFlags*}

These parameters affect loading delimited text (/J) and fixed field text (/F) data and column names. They are accepted no matter what the load type is but are ignored when they don't apply. These parameters should rarely be needed.

delimsStr is a string expression containing the characters that should act as delimiters for delimited file loads. The default is "\t," for tab and comma. You can specify the space character as a delimiter, but it is always given the lowest priority behind any other delimiters contained in *delimsStr*. The low priority means that if a line of text contains any other delimiter besides the space character, then that delimiter is used rather than the space character.

skipCharsStr is a string expression containing characters that should always be treated as garbage and skipped when they appear before a number. The default is "$" for space and dollar sign. This parameter should rarely be needed.

numConversionFlags is a bitwise parameter that controls the conversion of text to numbers. The bits are defined as follows:

bit 0: If set: dates are dd/mm/yy.
If cleared: dates are mm/dd/yy.

bit 1: If set: decimal character is comma.
If cleared: it is period.

bit 2: If set: thousands separators in numbers are ignored when loading delimited text only (LoadWave/J).

The thousands separator is the comma in 1,234 or, if comma is the decimal character, the dot in 1.234.

Most numeric data files do not use thousands separators and searching for them slows loading down so this bit should usually be 0.

This bit has no effect if the thousands separator (e.g., comma) is also a delimiter character as specified by delimsStr.

All other bits are reserved and must be cleared.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

If the /R flag is used to specify the date format, this overrides the setting of bit 0.

loadFlags is a bitwise parameter that controls the overall load. The bits are defined as follows:

bit 0: If set, ignores blanks at the end of a column. This is appropriate if the file contains columns of unequal length. Set *loadFlags* = 1 to set bit 0.

bit 1: If set, when the /W flag is specified and the line containing column labels starts with one or more space characters, the spaces are taken to be a blank column name. The resulting column will be named Blank. Use this if both the line containing column labels and the lines containing data start with leading spaces in a space-delimited file. Set loadFlags = 2 to set bit 1.

bit 2: If set: Disables pre-counting of lines of data. See **Loading Very Large Files** below.

bit 3: If set: Disables unescaping of backslash characters in text columns. See **Escape Sequences** below.

All other bits are reserved and you should use 0 for them.

/W Looks for wave names in a file. (With /G, /F, and /J.)

Use /W/A to read wave names from the file and then continue the load without displaying the normal wave name dialog.

Details

Without the /G, /F, /J, or /T flags, LoadWave loads Igor Binary files.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "`hd:Folder1:`" or "`C:\\Folder1\\`". See **Symbolic Paths** on page II-34 for details.

When loading a general text file, the delimiters are always tab, comma and space.

Loading Custom Date Formats

Here are some examples showing custom date formats and how you would specify them using the /R flag:

Date Format	Specification
October 11, 1999	`/R={English, 2, 4, 1, 1, "Month DayOfMonth, Year", 40}`
Oct 11, 1999	`/R={English, 2, 3, 1, 1, "Month DayOfMonth, Year", 40}`
11 October 1999	`/R={English, 2, 4, 1, 1, "DayOfMonth Month Year", 40}`
11 Oct 1999	`/R={English, 2, 3, 1, 1, "DayOfMonth Month Year", 40}`
10/11/99	`/R={English, 1, 2, 1, 1, "Month/DayOfMonth/Year", 40}`
11-10-99	`/R={English, 1, 2, 2, 1, "DayOfMonth-Month-Year", 40}`
11-Jun-99	`/R={English, 1, 3, 2, 1, "DayOfMonth-Month-Year", 40}`
991011	`/R={English,1,2,2,1,"YearMonthDayOfMonth", 40}`
19991011	`/R={English,2,2,2,1,"YearMonthDayOfMonth", 40}`

When loading data as delimited text, if you use a date format containing a comma, such as "October 11, 1999", you must use the /V flag to make sure that LoadWave will not treat the comma as a delimiter.

When loading a date format that consists entirely of digits, such as 991011, you must use the LoadWave/B to specify that the data is a date. Otherwise, LoadWave will treat it as a regular number.

Loading Very Large Files

The number of waves (columns) or points (rows) that LoadWave can handle when loading a text file is limited only by available memory.

You can improve the speed and efficiency of loading very large files (i.e., more than 50,000 lines of data) using the *numLines* parameter of the /L flag. Normally this parameter is used to load a section of the file instead of the whole file. However, in delimited, general text and fixed field text loads, the *numLines* parameter also specifies how many rows the waves should initially have. Thus all of the required memory is allocated at the start of the load, rather than increasing the number of wave rows over and over as more lines of data are loaded. When loading very large files, if you know the exact number of lines of data in the file, use the *numLines* parameter of the /L flag. If you don't know the exact number of lines, you can provide a number that is guaranteed to be larger.

As of Igor Pro 6.02, if you omit the /L flag or if the *numLines* parameter is zero, and if you are loading a file greater than 500,000 bytes, and if you are running on Windows, LoadWave will automatically count the lines of data in the file so that the entire wave can be allocated before data loading starts. This acts as if you used /L and set *numLines* to the exact correct value. For very large files on Windows, this can speed the loading process considerably. For small files on Windows and for files of any size on Macintosh, it actually makes the load slower. That's why this feature takes effect only on Windows and only for files of greater than 500,000 bytes. You can disable this feature by using the /V flag and setting bit 2 to 1.

Escape Sequences

An escape sequence is a two-character sequence used to represent special characters in plain text. Escape sequences are introduced by a backslash character.

By default, in a text column, LoadWave interprets the following escape sequences: \t (tab), \n (linefeed), \r (carriage-return), \\ (backslash), \" (double-quote) and \' (single-quote). This works well with Igor's **Save** operation which uses escape sequences to encode the first four of these characters.

If you are loading a file that does not use escape sequences but which does contain backslashes, you can disable interpretation of these escape sequences by setting bit 3 of the *loadFlags* parameter of the /V flag. This is mainly of use for loading a text file that contains unescaped Windows file system paths.

Generating Wave Names

The /N flag automatically names new waves "wave" (or *baseName* if =*baseName* is used) plus a digit. The digit starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The /A flag is like /N except that it skips names already in use.

Specifying Characteristics of Individual Columns

The /B=*columnInfoStr* flag provides information to LoadWave for each column in a delimited text (/J), fixed field text (/F) or general text (/G) file. The flag overrides LoadWave's normal behavior. In most cases, you will not need to use it.

columnInfoStr is constructed as follows:

```
"<column info>;<column info>; … ;<column info>;"
```

where <column info> consists of one or more of the following:

C=<number> The number of columns controlled by this column info specification. <number> is an integer greater than or equal to one.

F=<format> A code that specifies the data type of the column or columns. <format> is an integer from -2 to 10. The meaning of the <format> is:

- -2: Text. The column will be loaded into a text wave.
- -1: Format unknown. It will deduce the format.
- 0 to 5: Numeric.
- 6: Date.
- 7: Time.
- 8: Date/Time.
- 9: Octal number.
- 10: Hexadecimal number.

The F= flag is used for delimited text and fixed field text files only. It is ignored for general text files.

N=<name> A name to use for the column. <name> can be a standard name (e.g., wave0) or a quoted liberal name (e.g., 'Heart Rate'). If <name> is '_skip_' (including single quotation marks) then LoadWave will skip the column.

The N= flag works for delimited text, fixed field text and general text files.

T=<numtype> A number that specifies what the numeric type for the column should be. This flag overrides the LoadWave/D flag. It has no effect on columns whose format is text. <numtype> must be one of the following:

- 2: 32-bit float.
- 4: 64-bit float.
- 8: 8-bit signed integer.

16: 16-bit signed integer.

32: 32-bit signed integer.

72: 8-bit unsigned integer.

80: 16-bit unsigned integer.

96: 32-bit unsigned integer.

W=<width> The column field width for fixed field files. <width> is an integer greater than or equal to one. Fixed width files are FORTRAN-style files in which a fixed number of characters is allocated for each column and spaces are used as padding.

The W= flag is used for fixed field text only.

Here is an example of the /B=*columnInfoStr* flag:

```
/B="C=1,F=-2,T=2,W=20,N=Factory; C=1,F=6,W=16,T=4,N=MfgDate;
C=1,F=0,W=16,T=2,N=TotalUnits; C=1,F=0,W=16,T=2,N=DefectiveUnits;"
```

This example is shown on two lines but in a real command it would be on a single line. In a procedure, it could be written as:

```
String columnInfoStr = ""
columnInfoStr += "C=1,F=-2,T=2,W=20,N=Factory;"
columnInfoStr += "C=1,F=6,T=4,W=16,N=MfgDate;"
columnInfoStr += "C=1,F=0,T=2,W=16,N=TotalUnits;"
columnInfoStr += "C=1,F=0,T=2,W=16,N=DefectiveUnits;"
```

Note that each flag inside the quoted string ends with either a comma or a semicolon. The comma separates one flag from the next within a particular column info specification. The semicolon marks the end of a column info specification. The trailing semicolon is required. Spaces and tabs are permitted within the string.

This example provides information about a file containing four columns.

The first column info specification is "`C=1;F=-2,T=2,W=20,N=Factory;`". This indicates that the specification applies to one column, that the column format is text, that the numeric format is single-precision floating point (but this has no effect on text columns), that the column data is in a fixed field width of 20 characters, and that the wave created for this column is to be named Factory.

The second column info specification is "`C=1;F=6,T=4,W=16,N=MfgDate;`". This indicates that the specification applies to one column, that the column format is date, that the numeric format is double-precision floating point (double precision should always be used for dates), that the column data is in a fixed field width of 16 characters, and that the wave created for this column is to be named MfgDate.

The third column info specification is "`C=1;F=0,T=2,W=16,N=TotalUnits;`". This indicates that the specification applies to one column, that the column format is numeric, that the numeric format is single-precision floating point, that the column data is in a fixed field width of 16 characters, and that the wave created for this column is to be named TotalUnits.

The fourth column info specification is the same as the third except that the wave name is DefectiveUnits.

All of the items in a column specification are optional. The default value for each item in the column info specification is as follows:

C=<number> C=1. Specifies that the column info describes one column.

F=<format> F=-1. Determines the format as dictated by the /K flag. If /K=0 is used, LoadWave will automatically determine the column format.

N=<name> N=_auto_. Generates the wave name as it would if the /B flag were omitted.

T=<numtype> Defaults to T=4 (double precision) if the LoadWave/D flag is used or to T=2 (single precision) if the /D flag is omitted.

W=<width> W=0. For a fixed width file, LoadWave will use the default field width specified by the /F flag unless you provide an explicit field width greater than 0 using W=<width>.

Taking advantage of the default values, we could abbreviate the example as follows:

```
/B="F=-2,W=20,N=Factory; F=6,T=4,W=16,N=MfgDate;
W=16,N=TotalUnits; W=16,N=DefectiveUnits;"
```

If the file were not a fixed field text file, we would omit the W= flag and the example would become:

```
/B="F=-2,N=Factory;F=6,T=4,N=MfgDate;N=TotalUnits;N=DefectiveUnits;"
```

Here are some more examples and discussion that illustrate the use of the /B=*columnInfoStr* flag.

In this example, the /B flag is used solely to specify the name to use for the waves created from the columns in the file:

```
/B="N=WaveLength; N=Absorbance;"
```

The wave names in the previous example are standard names. If you want to use liberal names, such as names containing spaces or dots, you must use single quotes. For example:

```
/B="N='Wave Number'; N='Reflection Angle';"
```

The name that you specify via N= can not be used if overwrite is off and there is already a wave with this name or if the name conflicts with a macro, function or operation or variable. In these cases, LoadWave generates a unique name by adding one or more digits to the name specified by the N= flag for the column in question. You can avoid the problem of a conflict with another wave name by using the overwrite (/O) flag or by loading your data into a newly-created data folder. You can minimize the likelihood of a name conflict with a function, operation or variable by avoiding vague names.

If you specify the same name in two N= flags, LoadWave will generate an error, so make sure that the names are unique.

Except if the specified name is '_skip_', the N= flag generates a name for one column only, even if the C= flag is used to specify multiple columns. Consider this example:

```
/B="C=10,N=Test;"
```

This ostensibly uses the name Test for 10 columns. However, wave names must be unique, so LoadWave will not do this. It will use the name Test for just the first column and the other columns will receive default names.

Also, when loading data into a matrix wave, LoadWave uses only one name. If you specify more than one name, only the first is used.

In this example, the /B flag solely specifies the format of each column in the file. The file in question starts with a text column, followed by a date column, followed by 3 numeric columns.

```
/B="F=-2; F=6; C=3,F=0"
```

In most cases, it is not necessary to use the F= flag because LoadWave can automatically deduce the formats. The flag is useful for those cases where it deduces the column formats incorrectly. It is also useful to force LoadWave to interpret a column as octal or hexadecimal because LoadWave can not automatically deduce these formats.

The numeric codes (0…10) used by the F= flag are the same as the codes used by the ModifyTable operation. If you create a table using the /E flag, the F= flag controls the numeric format of table columns.

The code -1 is not a real column format code. If you use F=-1 for a particular column, LoadWave will deduce the format for that column from the column text.

In this example, the /B flag is used solely to specify the width of each column in a fixed field file. This file contains a 20 character column followed by ten 16 character columns followed by three 24 character columns.

```
/B="C=1,W=20; C=10,W=16; C=3,W=24"
```

The field widths specified via W= override the default field width specified by the /F flag. If all of the columns in the file have the same field width then you can use just the /F flag.

You can load a subset of the columns in the file using the /L flag. Even if you do this, the column info specifications that you provide via the /B flag start from the first column in the file, not from the first column to be loaded.

Output Variables

LoadWave sets the following variables:

`V_flag`	Number of waves loaded.
`S_fileName`	Name of the file being loaded.
`S_path`	File system path to the folder containing the file.
`S_waveNames`	Semicolon-separated list of the names of loaded waves.

The setting of S_path was added in Igor Pro 3.14. S_path uses Macintosh path syntax (e.g., "`hd:FolderA:FolderB:`"), even on Windows. It includes a trailing colon. If LoadWave is loading from the Clipboard, S_path is set to `""`.

When LoadWave presents an Open File dialog and the user cancels, V_flag is set to 0 and S_fileName is set to `""`.

The **ImageLoad** operation.

See Chapter II-9, **Importing and Exporting Data** for further information on loading waves, including loading multidimensional data from HDF, PICT, TIFF and other graphics files. Check the "More Extensions:File Loaders" folder other file-loader extensions.

Setting Bit Parameters on page IV-12 for further details about bit settings.

Loess

```
Loess [flags] srcWave = srcWaveName [, factors = factorWaveName1
    [, factorWaveName2 …]]
```

The Loess operation smooths *srcWaveName* using locally-weighted regression smoothing. This algorithm is sometimes classified as a "nonparametric regression" procedure. The regression can be constant, linear, or quadratic. A robust option that ignores outliers is available. See **Basic Algorithm**, **Robust Algorithm**, and **References** for additional details and terminology.

This implementation works with waveforms, XY pairs of waves, false-color images, matrix surfaces, and multivariate data (one dependent data wave with multiple independent variable data waves).

Unlike the **FilterFIR** operation, Loess discards any NaN input values and will not generate a result that is wholly NaN.

Parameters

srcWaveName is the input data to be smoothed. It may be a one-dimensional or a two-dimensional wave, and it may contain NaNs.

When no /DEST flag is specified, Loess will overwrite *srcWaveName* with the smoothed result.

If *srcWaveName* is one-dimensional and no factors are provided, X values are derived from the X scaling of *srcWaveName*.

If *srcWaveName* is two-dimensional, the factors keyword is not permitted and the X and Y values are derived from the X and Y scaling of *srcWaveName*.

Higher dimensions of *srcWaveName* are not supported.

The optional factors parameter(s) provide the independent variable value(s) that correspond to the observed value in *srcWaveName*.

Note: Cleveland et al. (1992) use the term "multiple factors" instead of "multivariate", hence the keyword name "factors" is used to denote these waves.

Use one factors wave when *srcWaveName* is the one-dimensional Y wave of an XY data pair:

```
srcWaveName[i] = someFunction(factorWaveName1[i])
```

Use multiple factors waves when *srcWaveName* contains the values of a multivariate function. "Multivariate" means that *srcWaveName* contains the observed results of a process that combines multiple independent input variables:

```
srcWaveName[i] = someFunction(factorWaveName1[i], factorWaveName2[i],…)
```

A maximum of 10 factors waves is supported.

All factors wave(s) must be numeric, noncomplex, one-dimensional and have the same number points as *srcWaveName*.

Any NaN values in *srcWaveName*[i], *factorWaveName1*[i], *factorWaveName2*[i], … cause all corresponding values to be ignored. Factors waves may contain NaN values only when /DFCT is specified.

Loess does not support NaNs in any of *destFactorWaveName1*, *destFactorWaveName2*,… and the results are undefined.

Flags

/CONF={*confInt*, *ciPlusWaveName* [,*ciMinusWaveName*]}
: *confInt* specifies the confidence interval (a probability value from 0 to 1). *ciPlusWaveName* and the optional *ciMinusWaveName* are the names of new or overwritten output waves to hold the fitted value ± the confidence interval.

  Note: /CONF uses large memory allocations, approximately N*N*8 bytes, where N is the number of points in *srcWaveName* (see **Memory Details**).

/DEST=*destWaveName*
: Specifies the name of the wave to hold the smoothed data. It creates *destWaveName* if it does not already exist or overwrites it if it does. The x (and possibly y) scaling

of *destWave* determines the independent (factor) coordinates unless /DFCT={*destFactorWaveName1* [,*destFactorWaveName2*...]} is also specified.

/DFCT
Specifies that the /DEST wave's x (and possibly y) scaling determines the independent (factor) coordinates at which to compute the smoothed data.

/DFCT={*destFactorWaveName1* [,*destFactorWaveName2*…]}
Specifies the names of one-dimensional waves providing the independent coordinates at which to compute the smoothed data.

If /DFCT={...} is used, the same number of waves must be specified for /DFCT and for factors = {*factorWaveName1* [, *factorWaveName2*…]}, though their lengths may (and usually will) be different. The length of *destFactorWaveName* waves must be the same as that of the *destWaveName* wave.

All destination factor waves must be numeric, noncomplex, and one-dimensional. The number of destination factor waves must match the number of source factor waves (if specified), or match the dimensionality of *srcWaveName* (one destination factor wave if *srcWaveName* is one-dimensional, two destination factors waves if *srcWaveName* is two-dimensional.)

The values in the destination factor waves may not be NaN.

/E=*extrapolate*
Set *extrapolate* to nonzero to use a slower fitting method that computes values beyond the domain defined by the source factors. This is the "surface" parameter named "direct" in Cleveland et al. (1992). The default is *extrapolate* = 0, which uses the "interpolate" surface parameter, instead.

/N=*neighbors*
Specifies the number of values in the smoothing window.

If *neighbors* is even, the next larger odd number is used. When *neighbors* is less than two, no smoothing is done.

The default is `0.5*numpnts(`*`srcWaveName`*`)` rounded up to the next odd integer or 3, whichever is larger.

Use either /N or /SMTH, but not both.

/NORM [=*norm*]
Set *norm* to 0 when specifying multiple factors and they all have the same scale and meaning, for example multiple factors all in units of meters.

The default is *norm* = 1, which normalizes each factor independently when computing the weighting function. This is appropriate when the factors are not dimensionally related, for example one factor measures wavelength and another measures temperature.

/ORD=*order*
Specifies the regression (fitting) order, the *d* parameter in Cleveland (1977):

order=0: Fits a constant to the locally-weighted neighbors around each point.

order=1: Fits a line to the locally-weighted neighbors around each point (Lowess smoothing).

order=2: Default; fits a quadratic (Loess smoothing).

/PASS=*passes*
The number of iterations of local weighting and regression fitting performed. The minimum is 1 and the default is 4. In Cleveland (1977), *passes* corresponds to *r*.

/R [=*robust*]
Set *robust* to nonzero to use a robust fitting method that uses a bisquare weight function instead of the normal tricube weight function. This corresponds to the "symmetric" family in Cleveland et al. (1992). The robust method is less affected by outliers. The default is *robust* = 0, which is the "gaussian" family in Cleveland et al. (1992).

/SMTH=*sf*
Another way to express the number of values in the smoothing window, $0 \le sf \le 1$. The default is 0.5.
